The boiling point of the solution is  $100.000^\circ\text{C} + 0.0114^\circ\text{C} = \mathbf{100.011^\circ\text{C}}$ , and the freezing point is  $0.000^\circ\text{C} - 0.0413^\circ\text{C} = \mathbf{-0.041^\circ\text{C}}$ . Note that  $\Delta T_b$  is added and  $\Delta T_f$  is subtracted.

(continued)

**Example 12.10** (continued)**Solution Essentials:**

- Boiling-point elevation ( $\Delta T_b = K_b c_m$ )
- Freezing-point depression ( $\Delta T_f = K_f c_m$ )
- Boiling-point-elevation constant ( $K_b$ )
- Freezing-point-depression constant ( $K_f$ )
- Molality ( $m = \frac{\text{moles of solute}}{\text{kg of solvent}}$ )
- Solute
- Solvent

**Answer Check** When reporting the final answer for either freezing-point depression or boiling-point elevation, always make sure that the final answer makes sense. For example, a solvent that contains a nonvolatile solute will always boil at a higher than normal boiling-point temperature and freeze at a lower than normal freezing-point temperature, as is the case here. If you find a solution like the one in this problem that has water as the solvent boiling at less than  $100^\circ\text{C}$  or freezing above  $0^\circ\text{C}$ , you will know that you have made an error.

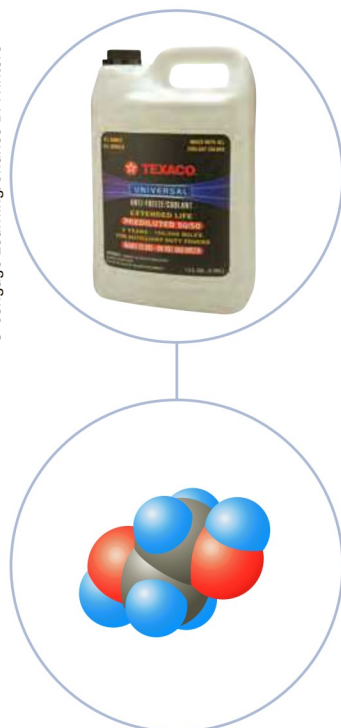

**Exercise 12.13** How many grams of ethylene glycol,  $\text{CH}_2\text{OHCH}_2\text{OH}$ , must be added to 37.8 g of water to give a freezing point of  $-0.150^\circ\text{C}$ ?

See Problems 12.69 and 12.70.

The boiling-point elevation and the freezing-point depression of solutions have a number of practical applications. We mentioned in the chapter opening that ethylene glycol is used in automobile radiators as an antifreeze because it lowers the freezing point of the coolant (Figure 12.22). The same substance also helps prevent the radiator coolant from boiling away by elevating the boiling point. Sodium chloride and calcium chloride are spread on icy roads in the winter to lower the melting point of ice and snow below the temperature of the surrounding air. Salt–ice mixtures are used as freezing mixtures in home ice cream makers. Melting ice cools the ice cream mixture to the freezing point of the solution, which is well below the freezing point of pure water.

Colligative properties are also used to obtain molecular weights. Although the mass spectrometer is now often used for routine determinations of the molecular weight of pure substances, colligative properties are still employed to obtain information about the species in solution. Freezing-point depression is often used because it is simple to determine a melting point or a freezing point (Figure 12.23). From the freezing-point lowering, you can calculate the molal concentration, and from the molality, you can obtain the molecular weight. The next two examples illustrate these calculations.

© Cengage Learning/Charles D. Winters

**Figure 12.22** ◀

**Automobile antifreeze mixtures**

The main ingredient of automobile antifreeze mixtures is ethylene glycol,  $\text{CH}_2\text{OHCH}_2\text{OH}$ . This substance has low vapor pressure, so it does not easily vaporize away. It is relatively cheap, being manufactured from ethylene,  $\text{C}_2\text{H}_4$ , which is obtained from petroleum. Ethylene glycol is also used to produce polyester fibers and plastics. The substance has a sweet taste (the name glycol derives from the Greek word *glukus*, meaning “sweet”) but is poisonous.

**Figure 12.23** ▲

**Determination of the freezing point of a liquid** The liquid is cooled by means of a freezing mixture. To control the rate of temperature decrease, the liquid is separated from the freezing mixture by an air space.

**Example 12.11** Calculating the Molecular Weight of a Solute from Molality**Gaining Mastery Toolbox****Critical Concept 12.11**

Molality is the ratio of moles of solute per kg of solvent. For a given solution, this ratio will be constant regardless of the temperature of the solution.

**Solution Essentials:**

- Molality  $\left(m = \frac{\text{moles of solute}}{\text{kg of solvent}}\right)$
- Molecular weight

A solution is prepared by dissolving 0.131 g of a substance in 25.4 g of water. The molality of the solution is determined by freezing-point depression to be 0.056 *m*. What is the molecular weight of the substance?

**Problem Strategy** The key to this problem is to determine the moles of substance in the sample. Recall that if you know the molality of a substance (given in the problem), you can determine the moles of substance present in 1 kg of solvent (0.056 mol substance/1.0 kg H<sub>2</sub>O). You then can use this ratio to determine the moles of substance present in the mass of water used to prepare the sample solution (moles of substance/25.4 × 10<sup>-3</sup> kg H<sub>2</sub>O). Now you know the moles of substance, its molar mass equals mass of substance (0.131 g) divided by moles of substance. The molecular weight (in amu) has the same numerical value as molar mass in g/mol.

**Solution** The molality of an aqueous solution is

$$\text{Molality} = \frac{\text{moles of substance}}{\text{kg H}_2\text{O}}$$

Hence, for the given solution, we can use the following proportional relationship:

$$\frac{0.056 \text{ mol}}{1 \text{ kg H}_2\text{O}} = \frac{\text{moles of substance}}{25.4 \times 10^{-3} \text{ kg H}_2\text{O}}$$

Rearranging this equation, you get

$$\text{Moles of substance} = \frac{0.056 \text{ mol}}{\text{kg H}_2\text{O}} \times 25.4 \times 10^{-3} \text{ kg H}_2\text{O} = 1.42 \times 10^{-3} \text{ mol}$$

(An extra digit is retained for further computation.) The molar mass of the substance equals

$$\text{Molar mass} = \frac{0.131 \text{ g}}{1.42 \times 10^{-3} \text{ mol}} = 92.3 \text{ g/mol}$$

You round the answer to two significant figures. The molecular weight is **92 amu**.

**Answer Check** Mistakes often give unreasonable values. For example, if you calculated the molality by dividing moles of substance by g H<sub>2</sub>O (instead of kg H<sub>2</sub>O), you would have obtained a molecular weight of 0.092 amu. Because the atomic mass of H (the lightest element) is 1.01 amu, a value of 0.092 amu is not possible. Very large molecular masses, like 92,000 amu, should also set off alarm bells (unless you have reason to believe the material is polymeric or biological). Typical molecular substances have molecular weights that range from tens up to hundreds of amu.

**Exercise 12.14** A 0.930-g sample of ascorbic acid (vitamin C) was dissolved in 95.0 g of water. The concentration of ascorbic acid, as determined by freezing-point depression, was 0.0555 *m*. What is the molecular weight of ascorbic acid?

See Problems 12.73 and 12.74.

**Example 12.12** Calculating the Molecular Weight from Freezing-Point Depression**Gaining Mastery Toolbox****Critical Concept 12.12**

The change in freezing point of a solution is directly proportional to the molality of the solution. For a given solution, if the change in freezing point is known, then the molality of the solution can be calculated.

Camphor is a white solid that melts at 179.5°C. It has been used to determine the molecular weights of organic compounds because of its unusually large freezing-point-depression constant (40°C/*m*), which allows ordinary thermometers to be used. The organic substance is dissolved in melted camphor, and then the melting point of the solution is determined. a. A 1.07-mg sample of a compound was dissolved in 78.1 mg of camphor. The solution melted at 176.0°C. What is the molecular weight of the compound? b. If the empirical formula of the compound is CH, what is the molecular formula? *(continued)*

**Example 12.12** (continued)**Solution Essentials:**

- Freezing-point depression ( $\Delta T_f = K_f c_m$ )
- Freezing-point-depression constant ( $K_f$ )
- Molality ( $m = \frac{\text{moles of solute}}{\text{kg of solvent}}$ )
- Molecular weight

**Problem Strategy**

a. The key to this problem is to determine the molality of the solution. Given the information in the problem, the equation for freezing-point depression provides a path for determining the solution molality. From the melting point of the solution, calculate the freezing-point depression,  $\Delta T_f$ ; then solve the equation  $\Delta T_f = K_f c_m$  for the molality,  $m$ . Use the method of the preceding example to obtain the molecular weight, given the mass of the sample and the molality of the solution. b. See Example 3.12 for the relation between number of empirical formula units  $n$ , empirical formula mass, and molecular weight.

**Solution**

a. The freezing-point lowering is

$$\Delta T_f = (179.5 - 176.0)^\circ\text{C} = 3.5^\circ\text{C}$$

so the molality of the solution is

$$\frac{\Delta T_f}{K_f} = \frac{3.5^\circ\text{C}}{40^\circ\text{C}/m} = 0.088 m$$

From this you compute the moles of the compound that are dissolved in 78.1 mg of camphor (see Example 12.11).

$$0.088 \text{ mol/kg} \times 78.1 \times 10^{-6} \text{ kg} = 6.9 \times 10^{-6} \text{ mol}$$

The molar mass of the compound is

$$M_m = \frac{1.07 \times 10^{-3} \text{ g}}{6.9 \times 10^{-6} \text{ mol}} = 1.6 \times 10^2 \text{ g/mol}$$

The molecular weight is **160 amu** (two significant figures).

b. The empirical formula weight of CH is 13 amu. Therefore, the number of CH units in the molecule is

$$n = \frac{\text{molecular weight}}{\text{empirical formula weight}} = \frac{1.6 \times 10^2 \text{ amu}}{13 \text{ amu}} = 12$$

The molecular formula is **C<sub>12</sub>H<sub>12</sub>**.

**Answer Check** In calculations like this, which focus on molecular weight determinations, the concentrations (molality) of the solutions are typically on the order of that in this problem. If you calculate a concentration of solute that is very large, check for errors.

**Exercise 12.15** A 0.205-g sample of white phosphorus was dissolved in 25.0 g of carbon disulfide, CS<sub>2</sub>. The boiling-point elevation of the carbon disulfide solution was found to be 0.159°C. What is the molecular weight of the phosphorus in solution? What is the formula of molecular phosphorus?

See Problems 12.75 and 12.76.

**12.7 Osmosis**

Certain membranes allow smaller solvent molecules to pass through them but not larger, solvated solute particles, particularly not those of large molecular mass. Such a membrane is called *semipermeable* and might be an animal bladder, a vegetable tissue, or a piece of cellophane. Figure 12.24 depicts the operation of a semipermeable membrane. **Osmosis** is the phenomenon of solvent flow through a semipermeable membrane to equalize the solute concentrations on both sides of the membrane. When two solutions of the same solvent are separated by a semipermeable membrane, solvent

**Figure 12.24** ▲

**A semipermeable membrane separating water and an aqueous solution of glucose**

Here the membrane is depicted as being similar to a sieve—the pores are too small to allow the glucose molecules to pass. The actual mechanism in particular cases may be more complicated. For example, water may be absorbed on one side of the membrane and diffuse through it to the other side.

molecules migrate through the membrane in both directions. However, the solvent migration is faster from the solution of low solute concentration to the solution of high solute concentration.

Figure 12.25 shows an experiment that demonstrates osmosis. A concentrated glucose solution is placed in an inverted funnel whose mouth is sealed with a semipermeable membrane. The funnel containing the glucose solution is then placed in a beaker of pure water. As water flows from the beaker through the membrane into the funnel, the liquid level rises in the stem of the funnel.

The glucose solution continues to rise up the funnel stem until the downward pressure exerted by the solution above the membrane eventually stops the upward flow of solvent (water). In general, **osmotic pressure** is a colligative property of a solution equal to the pressure that, when applied to the solution, just stops osmosis.

The osmotic pressure,  $\pi$ , of a solution is related to the molar concentration of solute,  $M$ :

$$\pi = MRT$$

Here  $R$  is the gas constant and  $T$  is the absolute temperature. There is a formal similarity between this equation for osmotic pressure and the equation for an ideal gas:

$$PV = nRT$$

The molar concentration  $M$  of a gas equals  $n/V$ ; therefore,  $P = (n/V)RT = MRT$ .

To see the order of magnitude of the osmotic pressure of a solution, consider the aqueous solution described in Example 12.10. There you found that a solution that is about 0.02  $m$  has a freezing-point depression of

**a** Before reaching equilibrium, water molecules pass through the membrane, into the glucose solution in the inverted funnel at a greater rate than they return (osmosis). This causes the liquid level in the funnel to rise.

**b** The column of liquid in the funnel eventually reaches sufficient height to exert a downward pressure,  $\pi$  (the osmotic pressure), causing the rates of water molecules entering and leaving the glucose solution to become equal. Once the osmotic pressure,  $\pi$ , has been reached, osmosis stops, and the liquid level in the funnel has reached its maximum height.

**Figure 12.25** ▲

**An experiment in osmosis**

about 0.04°C. The molarity and molality of a dilute aqueous solution are approximately equal (see Example 12.7). Therefore, this solution will also be about 0.02 *M*. Hence, the osmotic pressure at 25°C (298 K) is

$$\begin{aligned}\pi &= MRT \\ &= 0.02 \text{ mol/L} \times 0.082 \text{ L}\cdot\text{atm}/(\text{K}\cdot\text{mol}) \times 298 \text{ K} \\ &= 0.5 \text{ atm}\end{aligned}$$

If this pressure were to be exerted by a column of a water solution, as in Figure 12.25, the column would have to be more than 4.5 m high.

In most osmotic-pressure experiments, much more dilute solutions are employed. Often osmosis is used to determine the molecular weights of macromolecular or polymeric substances. Polymers are very large molecules generally made up from a simple, repeating unit. A typical molecule of polyethylene, for instance, might have the formula  $\text{CH}_3(\text{CH}_2\text{CH}_2)_{2000}\text{CH}_3$ . Although polymer solutions can be fairly concentrated in terms of grams per liter, on a mole-per-liter basis they may be quite dilute. The freezing-point depression is usually too small to measure, although the osmotic pressure may be appreciable.

### Example 12.13 Calculating Osmotic Pressure

#### Gaining Mastery Toolbox

##### Critical Concept 12.13

At a given temperature, the osmotic pressure of a solution is directly proportional to the molarity of the solution. A concentrated solution can have a great osmotic pressure.

##### Solution Essentials:

- Osmotic pressure ( $\pi = MRT$ )
- Molarity
- Ideal gas constant
- Kelvin temperature

The formula for low-molecular-weight starch, a polymer that occurs in plants, is  $(\text{C}_6\text{H}_{10}\text{O}_5)_n$ , where *n* averages  $2.00 \times 10^2$ . When 0.798 g of starch is dissolved in 100.0 mL of water solution, what is the osmotic pressure, in mmHg, at 25°C?

**Problem Strategy** Calculations of osmotic pressure involve the formula  $\pi = MRT$ . In order to employ this equation here, we need to determine the molarity (*M*) of the solution. If we obtain the molecular weight of the starch, we can determine the number of moles of starch in the 0.798-g sample used to prepare the solution. Then, knowing the moles of starch and the volume of the solution (100.0 mL), we can calculate the molarity. After using the formula to determine osmotic pressure, convert the pressure from units of atm to mmHg.

**Solution** The molecular weight of  $(\text{C}_6\text{H}_{10}\text{O}_5)_{200}$  is 32,400 amu. The number of moles in 0.798 g of starch is

$$0.798 \text{ g starch} \times \frac{1 \text{ mol starch}}{32,400 \text{ g starch}} = 2.46 \times 10^{-5} \text{ mol starch}$$

The molarity of the solution is

$$\frac{2.46 \times 10^{-5} \text{ mol}}{0.1000 \text{ L solution}} = 2.46 \times 10^{-4} \text{ mol/L solution}$$

and the osmotic pressure at 25°C is

$$\begin{aligned}\pi &= MRT \\ &= 2.46 \times 10^{-4} \text{ mol/L} \times 0.0821 \text{ L}\cdot\text{atm}/(\text{K}\cdot\text{mol}) \times 298 \text{ K} \\ &= 6.02 \times 10^{-3} \text{ atm} = 6.02 \times 10^{-3} \text{ atm} \times \frac{760 \text{ mmHg}}{1 \text{ atm}} \\ &= \mathbf{4.58 \text{ mmHg}}\end{aligned}$$

For comparison, you can calculate the freezing-point depression. Assume that the molality is equal to the molarity (this is in effect the case for very dilute aqueous solutions). Then,

$$\Delta T_f = 1.86^\circ\text{C}/m \times 2.46 \times 10^{-4} m = 4.58 \times 10^{-4} ^\circ\text{C}$$

which is barely detectable with generally available equipment.

(continued)

**Example 12.13** (continued)

**Answer Check** When performing calculations that involve the formula for osmotic pressure, always make certain that your temperature is in kelvins and that you use the correct value of the ideal gas constant,  $R$ .

**Exercise 12.16** Calculate the osmotic pressure at 20°C of an aqueous solution containing 5.0 g of sucrose,  $C_{12}H_{22}O_{11}$ , in 100.0 mL of solution.

See Problems 12.77 and 12.78.

Osmotic pressure appears to be important for the rising of sap in a tree. During the day, water evaporates from the leaves of the tree, so the aqueous solution in the leaves becomes more concentrated and the osmotic pressure increases. Sap flows upward to dilute the water solution in the leaves.

Osmosis is important in many biological processes. ◀ A cell might be thought of (simplistically) as an aqueous solution enclosed by a semipermeable membrane. The solution surrounding the cell must have an osmotic pressure equal to that within the cell. Otherwise, water would either leave the cell, dehydrating it, or enter the cell and possibly burst the membrane. For intravenous feeding (adding a nutrient solution to the venous blood supply of a patient), it is necessary that the nutrient solution have exactly the same osmotic pressure as blood plasma. If it does not, the blood cells may collapse or burst as a result of osmosis (Figure 12.26).

The body has portions of organs that are at different osmotic pressures, and an active pumping mechanism is required to offset osmosis. For example, cells of the transparent tissue of the exterior eye, the cornea, have a more concentrated optical fluid than does the aqueous humor, a solution just behind the cornea (Figure 12.27). To prevent the cornea from taking up additional water from the aqueous humor, cells that pump water are located in the corneal tissue adjacent to the aqueous humor. Corneas that are to be stored and used for transplants must be removed from the globe of the eye soon after the donor's death. This prevents the clouding that occurs when the pumping mechanism fails (as its energy supply is depleted at death).

The process of *reverse osmosis* has been applied to the problem of purifying water. In particular, the method has been used to *desalinate* ocean water (that is, remove salts from seawater to make drinkable or industrially usable water). In normal osmosis, the solvent flows from a dilute solution through a membrane to a more concentrated solution. By applying a pressure equal to the osmotic pressure to the more concentrated solution, it is possible to stop the process of osmosis. By

**a** The osmotic pressure of the solution is greater than that of the cell; the cell has collapsed.

**b** The osmotic pressure of the solution is equal to that of the cell; the cell has its normal round shape with depressed center.

**c** The osmotic pressure of the solution is less than that of the cell; the cell has a bloated shape.

© David Phillips/Science Source

**Figure 12.26** ▲

**The importance of osmotic pressure to cells** Shown here are color-enhanced electron micrographs of red blood cells in solutions of various osmotic pressures.

Figure 12.27 ◀

**Parts of the eye** Certain cells in the cornea act as pumps to prevent osmosis of water from the aqueous humor.

application of an even greater pressure, the osmotic process can be reversed. Then, solvent flows from the concentrated solution (which could be ocean water) through a membrane to the more dilute solution (which could be more or less pure water).

### ✓ CONCEPT CHECK 12.6

Explain why pickles are stored in a brine (salt) solution. What would the pickles look like if they were stored in water?

## 12.8 Colligative Properties of Ionic Solutions

To explain the colligative properties of ionic solutions, you must realize that it is the total concentration of ions, rather than the concentration of ionic substance, that is important. For example, the freezing-point depression of 0.100 *m* sodium chloride solution is nearly twice that of 0.100 *m* glucose solution. You can explain this by saying that sodium chloride dissolves in water to form the ions Na<sup>+</sup> and Cl<sup>-</sup>. Each formula unit of NaCl gives two particles. You can write the freezing-point lowering more generally as

$$\Delta T_f = iK_f c_m$$

where *i* is the number of ions resulting from each formula unit and *c<sub>m</sub>* is the molality computed on the basis of the formula of the ionic compound. With ionic solutions, the equations for the other colligative properties must be modified in a similar fashion to include the factor *i*.

$$\text{Vapor-pressure lowering:} \quad \Delta P = iP_A^\circ X_B$$

$$\text{Boiling-point elevation:} \quad \Delta T_b = iK_b c_m$$

$$\text{Osmotic pressure:} \quad \pi = iMRT$$

The actual values for the colligative properties of ionic solutions agree with the previous equations only when the solutions are quite dilute. For example, the *i* values calculated from the freezing-point depression are usually smaller than the

number of ions obtained from the formula unit. For example, a 0.029 *m* aqueous solution of potassium sulfate,  $K_2SO_4$ , has a freezing point of  $-0.14^\circ\text{C}$ . Hence,

$$i = \frac{\Delta T_f}{K_f c_m} = \frac{0.14^\circ\text{C}}{1.86^\circ\text{C}/m \times 0.029 m} = 2.6$$

You might have expected a value of 3, on the basis of the fact that  $K_2SO_4$  ionizes to give three ions. ◀ At first, this was taken as evidence that salts were not completely ionized in solution. In 1923, however, Peter Debye and Erich Hückel were able to show that the colligative properties of salt solutions could be explained by assuming that the salt is completely ionized in solution but that the *activities*, or effective concentrations, of the ions are less than their actual concentrations as a result of the electrical interactions of the ions in solution. The *Debye–Hückel theory* allows us to calculate these activities. When this is done, excellent agreement is obtained for dilute solutions.

The value of  $i$  equal to  $\Delta T_f/K_f c_m$  is often called the van 't Hoff factor. Thus, the van 't Hoff factor for 0.029 *m*  $K_2SO_4$  is 2.6.

### Example 12.14 Determining Colligative Properties of Ionic Solutions

#### Gaining Mastery Toolbox

##### Critical Concept 12.14

Colligative properties depend on the total number of particles in solution. For dilute ionic solutions, the chemical formula of the soluble ionic compound is used to determine the number of ions (particles) in solution resulting from each formula unit ( $i$ ). For example, a solution of  $MgCl_2$  would have  $i = 3$  because one mol of  $MgCl_2$  produces three moles of ions in solution.

##### Solution Essentials:

- Number of ions from each formula unit ( $i$ )
- Freezing-point depression of ionic solution ( $\Delta T_f = iK_f c_m$ )
- Freezing-point-depression constant ( $K_f$ )
- Molality ( $m = \frac{\text{moles of solute}}{\text{kg of solvent}}$ )

Estimate the freezing point of a 0.010 *m* aqueous solution of aluminum sulfate,  $Al_2(SO_4)_3$ . Assume the value of  $i$  based on the formula of the compound.

**Problem Strategy** Because aluminum sulfate is a soluble ionic compound, we need to use a modified form of the freezing-point depression formula,  $\Delta T_f = iK_f c_m$ . To obtain  $i$ , we need to determine the number of ions produced when  $Al_2(SO_4)_3$  dissolves in water.

**Solution** When aluminum sulfate,  $Al_2(SO_4)_3$ , dissolves in water, it dissociates into five ions.

Therefore, you assume  $i = 5$ . The freezing-point depression is

$$\Delta T_f = iK_f c_m = 5 \times 1.86^\circ\text{C}/m \times 0.010 m = 0.093^\circ\text{C}$$

The estimated freezing point of the solution is  $0.000^\circ\text{C} - 0.093^\circ\text{C} = -0.093^\circ\text{C}$ .

**Answer Check** Whenever you have to solve a problem involving the colligative properties of aqueous solutions, always make your first step a determination of whether the solute is an ionic or a molecular compound. This information will point you to the correct form of the equation.

**Exercise 12.17** Estimate the boiling point of a 0.050 *m* aqueous  $MgCl_2$  solution. Assume a value of  $i$  based on the formula.

See Problems 12.79 and 12.80.

#### ✓ CONCEPT CHECK 12.7

Each of the following substances is dissolved in a separate 10.0-L container of water: 1.5 mol  $NaCl$ , 1.3 mol  $Na_2SO_4$ , 2.0 mol  $MgCl_2$ , and 2.0 mol  $KBr$ . Without doing extensive calculations, rank the boiling points of the solutions from highest to lowest.

## ► Colloid Formation

As we noted at the beginning of the chapter, colloids appear homogeneous like solutions, but they consist of comparatively large particles of one substance dispersed throughout another substance. We will look at colloids in the following section.

### 12.9 Colloids

A **colloid** is a dispersion of particles of one substance (the dispersed phase) throughout another substance or solution (the continuous phase). Fog is an example of a colloid: it

consists of very small water droplets (dispersed phase) in air (continuous phase). A colloid differs from a true solution in that the dispersed particles are larger than normal molecules, though they are too small to be seen with a microscope. The particles range from about  $1 \times 10^3$  pm to about  $2 \times 10^5$  pm in size.

### Tyndall Effect

Although a colloid appears to be homogeneous because the dispersed particles are quite small, it can be distinguished from a true solution by its ability to scatter light. *The scattering of light by colloidal-size particles* is known as the **Tyndall effect**. ▶ For example, the atmosphere appears to be a clear gas, but a ray of sunshine against a dark background shows up many fine dust particles by light scattering. Similarly, when a beam of light is directed through clear gelatin (a colloid, not a true solution), the beam becomes visible by the scattering of light from colloidal gelatin particles. The beam appears as a ray passing through the solution (Figure 12.28). When the same experiment is performed with a true solution, such as an aqueous solution of sodium chloride, the beam of light is not visible.

### Types of Colloids

Colloids are characterized according to the state (solid, liquid, or gas) of the dispersed phase and of the continuous phase. Table 12.4 lists various types of colloids and some examples of each. Fog and smoke are **aerosols**, which are *liquid droplets or solid particles dispersed throughout a gas*. An **emulsion** consists of *liquid droplets dispersed throughout another liquid* (as particles of butterfat are dispersed through homogenized milk). A **sol** consists of *solid particles dispersed in a liquid*.

### Hydrophilic and Hydrophobic Colloids

Colloids in which the continuous phase is water are divided into two major classes: hydrophilic colloids and hydrophobic colloids. A **hydrophilic colloid** is a colloid in which there is a strong attraction between the dispersed phase and the continuous phase (water). Many such colloids consist of macromolecules (very large molecules) dispersed in water. Except for the large size of the dispersed molecules, these colloids are like normal solutions. Protein solutions, such as gelatin in water, are hydrophilic colloids. Gelatin molecules are attracted to water molecules by London forces and hydrogen bonding.

A **hydrophobic colloid** is a colloid in which there is a lack of attraction between the dispersed phase and the continuous phase (water). Hydrophobic colloids are basically unstable. Given sufficient time, the dispersed phase aggregates into larger particles. In this behavior, they are quite unlike true solutions and hydrophilic colloids. The time taken to separate may be extremely

Although all gases and liquids scatter light, the scattering from a pure substance or true solution is quite small and usually not detectable. However, because of the considerable depth of the atmosphere, the scattering of light by air molecules can be seen. The blue color of the sky is due to the fact that blue light is scattered more easily than red light.

Figure 12.28 ▲

#### A demonstration of the Tyndall effect by a colloid

A light beam is visible perpendicular to its path only if light is scattered toward the viewer. The vessel on the left contains a colloid, which scatters light. The vessel on the right contains a true solution, which scatters negligible light.

Layers of ions surrounding charged colloidal particles

long, however. A colloid of gold particles in water prepared by Michael Faraday in 1857 is still preserved in the British Museum in London. This colloid is hydrophobic as well as a sol (solid particles dispersed in water).

Hydrophobic sols are often formed when a solid crystallizes rapidly from a chemical reaction or a supersaturated solution. When crystallization occurs rapidly, many centers of crystallization (called *nuclei*) form at the same time. Ions are attracted to these nuclei, and very small crystals form. These small crystals are prevented from settling out by the random thermal motion of the solvent molecules, which continue to buffet them.

You might expect these very small crystals to aggregate into larger crystals because the aggregation would bring ions of opposite charge into contact. However, sol formation appears to happen when, for some reason, each of the small crystals gets a preponderance of one kind of charge on its surface. For example, iron(III) hydroxide forms a colloid because an excess of iron(III) ion (Fe<sup>3+</sup>) is present on the surface, giving each crystal an excess of positive charge. These positively charged crystals repel one another, so aggregation to larger particles is prevented.

### Coagulation

An iron(III) hydroxide sol can be made to aggregate by the addition of an ionic solution, particularly if the solution contains anions with multiple charges (such as phosphate ions, PO<sub>4</sub><sup>3-</sup>). **Coagulation** is the process by which the dispersed phase of a colloid is made to aggregate and thereby separate from the continuous phase. You can picture what happens in the following way: A positively charged colloidal particle of iron(III) hydroxide gathers a layer of anions around it. The thickness of this layer is determined by the charge on the anions. The greater the magnitude of the negative charge, the more compact is the layer of charge. Phosphate ions, for example, gather more closely to the positively charged colloidal particles than do chloride ions (see Figure 12.29). If the ion layer is gathered close to the colloidal particle, the overall charge is effectively neutralized. In that case, two colloidal particles can approach close enough to aggregate.

The curdling of milk when it sours is another example of coagulation. Milk is a colloidal suspension in which the particles are prevented from aggregating because they have electric charges of the same sign. The ions responsible for the coagulation (curdling) are formed when lactose (milk sugar) ferments to lactic acid. A third example is the coagulation of a colloidal suspension of soil in river water when the water meets the concentrated ionic solution of an ocean. The Mississippi Delta was formed in this way.

**Exercise 12.18** Colloidal sulfur particles are negatively charged with thiosulfate ions, S<sub>2</sub>O<sub>3</sub><sup>2-</sup>, and other ions on the surface of the sulfur. Indicate which of the following would be most effective in coagulating colloidal sulfur: NaCl, MgCl<sub>2</sub>, or AlCl<sub>3</sub>.

See Problems 12.85 and 12.86.

### Association Colloids

When molecules or ions that have both a hydrophobic and a hydrophilic end are dispersed in water, they associate, or aggregate, to form colloidal-sized particles, or micelles. A **micelle** is a colloidal-sized particle formed in water by the association of molecules or ions that each have a hydrophobic end and a hydrophilic end. The hydrophobic ends point inward toward one another, and the hydrophilic ends are on the outside of the micelle facing the water. A colloid in which the dispersed phase consists of micelles is called an **association colloid**.

Ordinary soap in water provides an example of an association colloid. Soap consists of compounds such as sodium stearate, C<sub>17</sub>H<sub>35</sub>COONa. The stearate ion

has a long hydrocarbon end that is hydrophobic (because it is nonpolar) and a carboxyl group ( $\text{COO}^-$ ) at the other end that is hydrophilic (because it is ionic).

hydrophobic end

hydrophilic end

Stearate ion

In water solution, the stearate ions associate into micelles in which the hydrocarbon ends point inward toward one another and away from the water, and ionic carboxyl groups are on the outside of the micelle facing the water (Figure 12.30).

The cleansing action of soap occurs because oil and grease can be absorbed into the hydrophobic centers of soap micelles and washed away (Figures 12.31 and 12.32). Synthetic detergents also form association colloids. Sodium lauryl sulfate is a synthetic detergent present in toothpastes and shampoos.

Sodium lauryl sulfate

It has a hydrophilic sulfate group ( $-\text{OSO}_3^-$ ) and a hydrophobic dodecyl group ( $\text{C}_{12}\text{H}_{25}-$ , the hydrocarbon end).

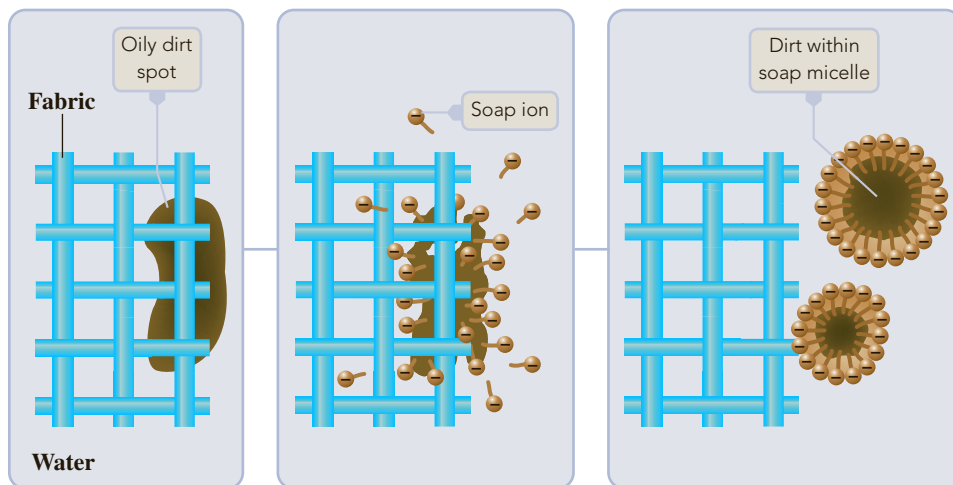

**Figure 12.30** ◀

**A stearate micelle in a water solution**  
Stearate ions associate in groups (micelles), with their hydrocarbon ends pointing inward. The ionic ends, on the outside of the micelle, point into the water solution.

**Figure 12.31** ▶

**The cleansing action of soap** The hydrocarbon ends of soap ions gather around an oil spot, forming a micelle that can be washed away in the water.

**Figure 12.32** ▶

**Formation of an association colloid of vegetable oil with soap**

© Cengage Learning

The detergent molecules we have discussed so far are classified in the trade as “anionics,” because they have a negative charge at the hydrophilic end. Other detergent molecules are “cationics,” because they have a positive charge at the hydrophilic end. An example is

© Cengage Learning

**Figure 12.33** ▲

**Commercial preparations containing cationic detergents** Many cationic detergents exhibit germicidal properties. For that reason, they are used in certain hospital antiseptics, mouthwashes, and eye-wetting solutions.

Many cationic detergents also have germicidal properties and are used in hospital disinfectants and in mouthwashes (Figure 12.33).

A CHEMIST Looks at ...

## The World's Smallest Test Tubes

Phospholipids are the main constituents of the membranes of living cells. These membranes enclose the chemical substances of a cell and allow these substances to carry on the reactions needed for life processes unimpeded by random events external to the membrane. Recently, chemists have prepared cell-like structures—*lipid vesicles*—from phospholipids and have used them to carry out chemical reactions by combining the contents of two lipid vesicles, with diameters from about 50 nanometers (billionths of a meter) to several micrometers (millionths of a meter). Richard Zare, at Stanford University, who was one of those who described these experiments, has called these lipid vesicles “the world’s smallest test tubes.”

Like the soap ions, phospholipids have the intriguing property of self-assembly into groups. Soap ions in water naturally group themselves into micelles. Phospholipids, however, have a chemical structure that, while similar to that of soap ions, precludes their assembly into micelles. Rather, they form layer structures. And under the right circumstances, a layer may fold back on itself like the skin of a basketball to enclose a space, forming a vesicle.

Lecithins are typical phospholipids. Lipids are biological substances like fats and oils that are soluble in organic solvents; phospholipids contain phosphate groups. (If you

are a label reader, you may have seen soy lecithin listed as an ingredient in food products such as bakery goods.) Here is the general structure of a lecithin:

R and R' denote long hydrocarbon groups, with perhaps 14 to 18 carbon atoms.

Note that, like a soap ion, a phospholipid has a hydrophobic end (the two hydrocarbon groups) and a hydrophilic end (an ionic portion containing a phosphate group,  $-\text{PO}_4^-$ ). Like soap ions, phospholipid molecules in water tend to associate so that their hydrophilic (or ionic) “heads” dip into the water, with their hydrophobic (or hydrocarbon) “tails” pointing away. However, the hydrocarbon tails of a phospholipid molecule are too bulky to associate into micelles and instead form a *bilayer*, a layer two molecules thick. Figure 12.34 shows a model of a cell membrane that displays this bilayer structure, with

**Figure 12.34** ▶

### A model of a cell membrane

The membrane consists of a phospholipid bilayer with protein molecules inserted in it.

(continued)

## A CHEMIST Looks at . . . The World's Smallest Test Tubes *(continued)*

two phospholipid layers, their hydrocarbon tails pointing inward toward each other. The hydrophilic heads are rendered in blue; the hydrophobic tails are in yellow. Note that the interior of a membrane (shown in pale green) is "oily" from the hydrocarbon groups and therefore repels molecules or ions dissolved in the water solutions outside and inside a cell. (A cell, though, must interact with its environment. Protein molecules embedded in the cell membrane form channels or active pumps to transport specific molecules and ions across the cell membrane.)

In one of their experiments, Zare and his colleagues brought two phospholipid vesicles, each about a micrometer in diameter and containing different reactant substances,

together under a special microscope. When the vesicles just touched, the researchers delivered an electrical pulse to them that opened a small pore in each vesicle. The two vesicles coalesced into one, and their contents reacted. The scientists detected the product molecules from the orange fluorescence they gave off when radiated with ultraviolet light. The techniques these researchers are developing should allow scientists to mimic the conditions in biological cells. And lipid vesicles might one day be designed to deliver drugs to specific cells, say cancer cells.

■ See Problems 12.113 and 12.114.

### ✓ CONCEPT CHECK 12.8

If electrodes that are connected to a direct current (DC) source are dipped into a beaker of colloidal iron(III) hydroxide, a precipitate collects at the negative electrode. Explain why this happens.

## ✓ A Checklist for Review

### Summary of Facts and Concepts

*Solutions* are homogeneous mixtures and can be gases, liquids, or solids. Two gases, for example, will mix in all proportions to give a gaseous solution, because gases are *miscible* in one another. Often one substance will dissolve in another only to a limited extent. The maximum amount that dissolves at equilibrium is the *solubility* of that substance. Solubility is explained in terms of the natural tendency toward disorder (say, by the mixing of two substances) and by the tendency to result in the strongest forces of attraction between species. The dissolving of one molecular substance in another is limited when intermolecular forces strongly favor the unmixed substances. When two substances have similar types of intermolecular forces, they tend to be miscible ("like dissolves like"). Ionic substances differ greatly in their solubilities in water, because solubility depends on the relative effects of *lattice energy* and *hydration energy*.

Solubilities usually vary with temperature. At higher temperatures, most gases will become less soluble in water, whereas most ionic solids will become more soluble. Pressure has a significant effect on the solubility only of a gas. A gas is more soluble in a liquid if the partial pressure of the gas is increased, which is in agreement with *Le Châtelier's principle*. According to *Henry's law*, the solubility of a gas is directly proportional to the partial pressure of the gas.

*Colligative properties* of solutions depend only on the concentration of solute particles. The concentration may be defined by the *molarity*, *mass percentage of solute*, *molarity*, or *mole fraction*. One example of a colligative property is the *vapor-pressure lowering* of a volatile solvent by the addition of a nonvolatile solute. According to *Raoult's law*, the vapor pressure of this solution depends on the mole fraction of solvent. Because adding a nonvolatile solute lowers the vapor pressure, the boiling point must be raised to bring the vapor pressure back to 1 atm (*boiling-point elevation*). Such a solution also exhibits a *freezing-point depression*. Boiling-point elevation and freezing-point depression are colligative properties. *Osmosis* is another colligative property. In osmosis, there is a flow of solvent through a semipermeable membrane in order to equalize the concentrations of solutions on the two sides of the membrane. Colligative properties may be used to measure solute concentration. In this way, one can determine the molecular weight of the solute. The colligative properties of an ionic solution depend on the concentration of ions, which you can obtain from the concentration of ionic compound and its formula. Interactions of ions in solution do affect the properties significantly, however.

A *colloid* is a dispersion of particles of one substance (about  $1 \times 10^3$  pm to  $2 \times 10^5$  pm in size) throughout another. Colloids can be detected by the *Tyndall effect*

(the scattering of light by colloidal-size particles). Colloids are characterized by the state of the dispersed phase and the state of the continuous phase. An aerosol, for example, consists of liquid droplets or solid particles dispersed in a gas. Colloids in water are hydrophilic or hydrophobic. A *hydrophilic colloid* consists of a dispersed phase that is attracted to the water. Many of these colloids have macromolecules dissolved in water. In *hydrophobic colloids*, there

is little attraction between the dispersed phase and the water. The colloidal particles may be electrically charged and repel one another, preventing aggregation to larger particles. An ionic solution can neutralize this charge so that the colloid will *coagulate*—that is, aggregate. An *association colloid* consists of molecules with a hydrophobic end and a hydrophilic end dispersed in water. These molecules associate into colloidal-size groups, or *micelles*.

## Learning Objectives

## Important Terms

### 12.1 Types of Solutions

- Define *solute* and *solvent*.
- Define *miscible fluid*.
- Provide examples of *gaseous solutions*, *liquid solutions*, and *solid solutions*.

**solute**  
**solvent**  
**miscible fluids**

### 12.2 Solubility and the Solution Process

- List the conditions that must be present to have a *saturated solution*, to have an *unsaturated solution*, and to have a *supersaturated solution*.
- Describe the factors that make one substance soluble in another.
- Determine when a *molecular solution* will form when substances are mixed.
- Learn what conditions must be met in order to create an *ionic solution*.

**saturated solution**  
**solubility**  
**unsaturated solution**  
**supersaturated solution**  
**hydration (of ions)**

### 12.3 Effects of Temperature and Pressure on Solubility

- State the general trends of the solubility of gases and solids with temperature.
- Explain how the solubility of a gas changes with temperature.
- Apply Henry's law. **Example 12.1**

**Le Châtelier's principle**  
**Henry's law**

### 12.4 Ways of Expressing Concentration

- Define *colligative property*.
- Define *molarity*.
- Define *mass percentage of solute*.
- Calculate with mass percentage of solute. **Example 12.2**
- Define *molality*.
- Calculate the molality of solute. **Example 12.3**
- Define *mole fraction*.
- Calculate the mole fraction of components. **Example 12.4**
- Convert molality to mole fractions. **Example 12.5**
- Convert mole fractions to molality. **Example 12.6**
- Convert molality to molarity. **Example 12.7**
- Convert molarity to molality. **Example 12.8**

**colligative properties**  
**mass percentage of solute**  
**molality**  
**mole fraction**

### 12.5 Vapor Pressure of a Solution

- Explain *vapor-pressure lowering* of a solvent.
- State *Raoult's law*.
- Calculate vapor-pressure lowering. **Example 12.9**
- Describe an *ideal solution*.

**vapor-pressure lowering**  
**Raoult's law**

**12.6 Boiling-Point Elevation and Freezing-Point Depression**

- Define *boiling-point elevation* and *freezing-point depression*.
- Calculate boiling-point elevation and freezing-point depression. **Example 12.10**
- Calculate the molecular weight of a solute from molality. **Example 12.11**
- Calculate the molecular weight from freezing-point depression. **Example 12.12**

**boiling-point elevation**  
**freezing-point depression**

**12.7 Osmosis**

- Describe a system where *osmosis* will take place.
- Calculate osmotic pressure. **Example 12.13**

**osmosis**  
**osmotic pressure**

**12.8 Colligative Properties of Ionic Solutions**

- Determine the colligative properties of ionic solutions. **Example 12.14**

**12.9 Colloids**

- Define *colloid*.
- Explain the *Tyndall effect*.
- Give examples of *hydrophilic colloids* and *hydrophobic colloids*.
- Describe *coagulation*.
- Explain how *micelles* can form an *association colloid*.

**colloid**  
**Tyndall effect**  
**aerosols**  
**emulsion**  
**sol**  
**hydrophilic colloid**  
**hydrophobic colloid**  
**coagulation**  
**micelle**  
**association colloid**

**Key Equations**

$$S = k_H P$$

$$\text{Mass percentage of solute} = \frac{\text{mass of solute}}{\text{mass of solution}} \times 100\%$$

$$\text{Molality} = \frac{\text{moles of solute}}{\text{kilograms of solvent}}$$

$$X_A = \frac{\text{moles of substance } A}{\text{total moles of solution}} P_A = P_A^{\circ} X_A$$

$$\Delta P = i P_A^{\circ} X_B$$

$$\Delta T_b = i K_b c_m$$

$$\Delta T_f = i K_f c_m$$

$$\pi = i M R T$$

**Questions and Problems****Self-Assessment and Review Questions**

**Key:** These questions test your understanding of the ideas you worked with in the chapter. These problems vary in difficulty and often can be used for the basis of discussion.

**12.1** Give one example of each: a gaseous solution, a liquid solution, a solid solution.

**12.2** What are the two factors needed to explain the differences in solubilities of substances?

**12.3** Explain in terms of intermolecular attractions why octane is immiscible in water.

**12.4** Explain why ionic substances show a wide range of solubilities in water.

**12.5** Using the concept of hydration, describe the process of dissolving a sodium chloride crystal in water.

**12.6** What is the usual solubility behavior of an ionic compound in water when the temperature is raised? Give an example of an exception to this behavior.

**12.7** Give one example of each: a salt whose heat of solution is exothermic and a salt whose heat of solution is endothermic.

**12.8** What do you expect to happen to a concentration of dissolved gas in a solution as the solution is heated?

**12.9** Explain why a carbonated beverage must be stored in a closed container.

**12.10** Pressure has an effect on the solubility of oxygen in water but a negligible effect on the solubility of sugar in water. Why?

**12.11** Four ways were discussed to express the concentration of a solute in solution. Identify them and define each concentration unit.

**12.12** When two beakers containing different concentrations of a solute in water are placed in a closed cabinet for a time, one beaker gains solvent and the other loses it, so that the concentrations of solute in the two beakers become equal. Explain what is happening.

**12.13** Explain the process of fractional distillation to separate a solution of two liquids into pure components.

**12.14** Explain why the boiling point of a solution containing a nonvolatile solute is higher than the boiling point of a pure solvent.

**12.15** List two applications of freezing-point depression.

**12.16** Explain the process of reverse osmosis to produce drinkable water from ocean water.

**12.17** One can often see “sunbeams” passing through the less dense portions of clouds. What is the explanation for this?

**12.18** Give an example of an aerosol, a foam, an emulsion, a sol, and a gel.

**12.19** Explain on the basis that “like dissolves like” why glycerol,  $\text{CH}_2\text{OHCHOHCH}_2\text{OH}$ , is miscible in water but benzene,  $\text{C}_6\text{H}_6$ , has very limited solubility in water.

**12.20** Explain how soap removes oil from a fabric.

**12.21** Calculate the number of moles of barium chloride in 427 g of a 3.17% by mass barium chloride solution?

**a**  $6.50 \times 10^{-2}$  mol

**b**  $7.83 \times 10^{-2}$  mol

**c**  $4.31 \times 10^{-2}$  mol

**d**  $7.81 \times 10^{-2}$  mol

**e**  $4.27 \times 10^{-2}$  mol

**12.22** The mole fraction of copper(II) nitrate in an aqueous copper(II) nitrate solution is 0.135. What is the molality of the copper(II) nitrate solution?

**a** 7.49 *m*

**b** 8.01 *m*

**c** 8.66 *m*

**d** 9.34 *m*

**e** 8.09 *m*

**12.23** If 291 g of a compound is added to 1.02 kg of water to increase the boiling point by  $5.77^\circ\text{C}$ , what is the molar mass of the added compound? (Assume a van 't Hoff factor of 1.)

**a** 31.1 g/mol

**b** 30.3 g/mol

**c** 28.5 g/mol

**d** 18.3 g/mol

**e** 25.3 g/mol

**12.24** A 5.1-g sample of  $\text{CaCl}_2$  is dissolved in a beaker of water. Which of the following statements is true of this solution?

**a** The solution will freeze at a lower temperature than pure water.

**b** The solution has a higher vapor pressure than pure water.

**c** The solution will boil at a lower temperature than pure water.

**d** Water is the solute in this solution.

**e** None of the other statements (a–d) are true.

## Concept Explorations

**Key:** Concept explorations are comprehensive problems that provide a framework that will enable you to explore and learn many of the critical concepts and ideas in each chapter. If you master the concepts associated with these explorations, you will have a better understanding of many important chemistry ideas and will be more successful in solving all types of chemistry problems. These problems are well suited for group work and for use as in-class activities.

### Colligative Properties I

**12.25** Consider two hypothetical pure substances,  $\text{AB}(s)$  and  $\text{XY}(s)$ . When equal molar amounts of these substances are placed in separate 500-mL samples of water, they undergo the following reactions:

**a** Which solution would you expect to have the lower boiling point? Why?

**b** Would you expect the vapor pressures of the two solutions to be equal? If not, which one would you expect to have the higher vapor pressure?

**c** Describe a procedure that would make the two solutions have the same boiling point.

**d** If you took 250 mL of the  $\text{AB}(aq)$  solution prepared above, would it have the same boiling point as the original solution? Be sure to explain your answer.

**e** The container of  $\text{XY}(aq)$  is left out on the bench top for several days, which allows some of the water to evaporate from the solution. How would the melting point of this solution compare to the melting point of the original solution?

### Colligative Properties II

**12.26** Equal numbers of moles of two soluble, substances, substance A and substance B, are placed into separate 1.0-L samples of water.

**a** The water samples are cooled. Sample A freezes at  $-0.50^\circ\text{C}$ , and Sample B freezes at  $-1.00^\circ\text{C}$ . Explain how the solutions can have different freezing points.

**b** You pour 500 mL of the solution containing substance B into a different beaker. How would the freezing point of this 500-mL portion of solution B compare to the freezing point of the 1.0-L sample of solution A?

- c Calculate the molality of the solutions of A and B. Assume that  $i = 1$  for substance A.
- d If you were to add an additional 1.0 kg of water to solution B, what would be the new freezing point of the solution? Try to write an answer to this question without using a mathematical formula.
- e What concentration (molality) of substances A and B would result in both solutions having a freezing point of  $-0.25^\circ\text{C}$ ?
- f Compare the boiling points, vapor pressure, and osmotic pressure of the original solutions of A and B. Don't perform the calculations; just state which is the greater in each case.

## Conceptual Problems

**Key:** These problems are designed to check your understanding of the concepts associated with some of the main topics presented in each chapter. A strong conceptual understanding of chemistry is the foundation for both applying chemical knowledge and solving chemical problems. These problems vary in level of difficulty and often can be used as a basis for group discussion.

**12.27** Even though the oxygen demands of trout and bass are different, they can exist in the same body of water. However, if the temperature of the water in the summer gets above about  $23^\circ\text{C}$ , the trout begin to die, but not the bass. Why is this the case?

**12.28** You want to purchase a salt to melt snow and ice on your sidewalk. Which one of the following salts would best accomplish your task using the least amount: KCl,  $\text{CaCl}_2$ ,  $\text{PbS}_2$ ,  $\text{MgSO}_4$ , or AgCl?

**12.29** Ten grams of the hypothetical ionic compounds XZ and YZ are each placed in a separate 2.0-L beaker of water. XZ completely dissolves, whereas YZ is insoluble. The energy of hydration of the  $\text{Y}^+$  ion is greater than the  $\text{X}^+$  ion. Explain this difference in solubility.

**12.30** Small amounts of a nonvolatile, nonelectrolyte solute and a volatile solute are each dissolved in separate beakers containing 1 kg of water. If the number of moles of each solute is equal:

- a Which solution will have the higher vapor pressure?
- b Which solution will boil at a higher temperature?

**12.31** A Cottrell precipitator consists of a column containing electrodes that are connected to a high-voltage direct current (DC) source. The Cottrell precipitator is placed in smokestacks to remove smoke particles from the gas discharged from an industrial plant. Explain how you think this works.

**12.32** Consider the following dilute  $\text{NaCl}(aq)$  solutions.

- a Which one will boil at a higher temperature?
- b Which one will freeze at a lower temperature?
- c If the solutions were separated by a semipermeable membrane that allowed only water to pass, which solution would you expect to show an increase in the concentration of NaCl?

**12.33** A green leafy salad wilts if left too long in a salad dressing containing vinegar and salt. Explain what happens.

**12.34** People have proposed towing icebergs to arid parts of the earth as a way to deliver freshwater. Explain why icebergs do not contain salts although they are formed by the freezing of ocean water (i.e., saltwater).

**12.35** If 1-mol samples of urea, a nonelectrolyte, sodium chloride, and calcium chloride are each dissolved in equal volumes of water in separate containers:

- a Which solution would have the highest boiling point?
- b Which solution would have the highest freezing point?

**12.36** Consider the following three beakers that contain water and a non-volatile solute. The solute is represented by the orange spheres.

- a Which solution would have the highest vapor pressure?
- b Which solution would have the lowest boiling point?
- c What could you do in the laboratory to make each solution have the same freezing point?

## Practice Problems

**Key:** These problems are for practice in applying problem-solving skills. They are divided by topic, and some are keyed to exercises (see the ends of the exercises). The problems are

arranged in matching pairs; the odd-numbered problem of each pair is listed first, and its answer is given in the back of the book.

### Types of Solutions

**12.37** Give an example of a liquid solution prepared by dissolving a gas in a liquid.

**12.38** Give an example of a solid solution prepared from two solids.

### Solubility

**12.39** Would boric acid,  $B(OH)_3$ , be more soluble in ethanol,  $C_2H_5OH$ , or in benzene,  $C_6H_6$ ?

**12.40** Would naphthalene,  $C_{10}H_8$ , be more soluble in ethanol,  $C_2H_5OH$ , or in benzene,  $C_6H_6$ ?

**12.41** Arrange the following substances in order of increasing solubility in hexane,  $C_6H_{14}$ :  $CH_2OHCH_2OH$ ,  $C_{10}H_{22}$ ,  $H_2O$ .

**12.42** Indicate which of the following is more soluble in ethanol,  $C_2H_5OH$ : acetic acid,  $CH_3COOH$ , or stearic acid,  $C_{17}H_{35}COOH$ .

**12.43** Which of the following ions would be expected to have the greater energy of hydration,  $Mg^{2+}$  or  $Al^{3+}$ ?

**12.44** Which of the following ions would be expected to have the greater energy of hydration,  $F^-$  or  $Cl^-$ ?

**12.45** Arrange the following alkaline-earth-metal iodates in order of increasing solubility in water and explain your reasoning:  $Ba(IO_3)_2$ ,  $Ca(IO_3)_2$ ,  $Sr(IO_3)_2$ ,  $Mg(IO_3)_2$ . Note that  $IO_3^-$  is a large anion.

**12.46** Explain the trends in solubility (grams per 100 mL of water) of the alkali-metal fluorides and permanganates.

	$Li^+$	$Na^+$	$K^+$	$Rb^+$	$Cs^+$
$F^-$	0.27	4.2	92	131	367
$MnO_4^-$	71	Very soluble	6.4	0.5	0.097

**12.47** The solubility of carbon dioxide in water is 0.161 g  $CO_2$  in 100 mL of water at  $20^\circ C$  and 1.00 atm. A soft drink is carbonated with carbon dioxide gas at 5.50 atm pressure. What is the solubility of carbon dioxide in water at this pressure?

**12.48** Nitrogen,  $N_2$ , is soluble in blood and can cause intoxication at sufficient concentration. For this reason, the U.S. Navy advises divers using compressed air not to go below 125 feet. The total pressure at this depth is 4.79 atm. If the solubility of nitrogen at 1.00 atm is  $1.75 \times 10^{-3}$  g/100 mL of water, and the mole percent of nitrogen in air is 78.1, what is the solubility of nitrogen in water from air at 4.79 atm?

### Solution Concentration

**12.49** How would you prepare 78.0 g of an aqueous solution that is 5.00% potassium iodide, KI, by mass?

**12.50** How would you prepare 455 g of an aqueous solution that is 7.00% sodium sulfate,  $Na_2SO_4$ , by mass?

**12.51** What mass of solution containing 5.00% potassium iodide, KI, by mass contains 258 mg KI?

**12.52** What mass of solution containing 6.50% sodium sulfate,  $Na_2SO_4$ , by mass contains 1.75 g  $Na_2SO_4$ ?

**12.53** Vanillin,  $C_8H_8O_3$ , occurs naturally in vanilla extract and is used as a flavoring agent. A 39.1-mg sample of vanillin was dissolved in 168.5 mg of diphenyl ether,  $(C_6H_5)_2O$ . What is the molality of vanillin in the solution?

**12.54** Lauryl alcohol,  $C_{12}H_{25}OH$ , is prepared from coconut oil; it is used to make sodium lauryl sulfate, a synthetic detergent. What is the molality of lauryl alcohol in a solution of 17.1 g lauryl alcohol dissolved in 185 g ethanol,  $C_2H_5OH$ ?

**12.55** Fructose,  $C_6H_{12}O_6$ , is a sugar occurring in honey and fruits. The sweetest sugar, it is nearly twice as sweet as sucrose (cane or beet sugar). How much water should be added to 1.75 g of fructose to give a 0.125 *m* solution?

**12.56** Caffeine,  $C_8H_{10}N_4O_2$ , is a stimulant found in tea and coffee. A sample of the substance was dissolved in 45.0 g of chloroform,  $CHCl_3$ , to give a 0.0946 *m* solution. How many grams of caffeine were in the sample?

**12.57** A 100.0-g sample of a brand of rubbing alcohol contains 65.0 g of isopropyl alcohol,  $C_3H_7OH$ , and 35.0 g of water. What is the mole fraction of isopropyl alcohol in the solution? What is the mole fraction of water?

**12.58** An automobile antifreeze solution contains 2.50 kg of ethylene glycol,  $CH_2OHCH_2OH$ , and 2.25 kg of water. Find the mole fraction of ethylene glycol in this solution. What is the mole fraction of water?

**12.59** A bleaching solution contains sodium hypochlorite,  $NaClO$ , dissolved in water. The solution is 0.650 *m*  $NaClO$ . What is the mole fraction of sodium hypochlorite?

**12.60** An antiseptic solution contains hydrogen peroxide,  $H_2O_2$ , in water. The solution is 0.610 *m*  $H_2O_2$ . What is the mole fraction of hydrogen peroxide?

**12.61** Concentrated hydrochloric acid contains 1.00 mol HCl dissolved in 3.31 mol H<sub>2</sub>O. What is the mole fraction of HCl in concentrated hydrochloric acid? What is the molal concentration of HCl?

**12.62** Concentrated aqueous ammonia contains 1.00 mol NH<sub>3</sub> dissolved in 2.50 mol H<sub>2</sub>O. What is the mole fraction of NH<sub>3</sub> in concentrated aqueous ammonia? What is the molal concentration of NH<sub>3</sub>?

**12.63** Oxalic acid, H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>, occurs as the potassium or calcium salt in many plants, including rhubarb and spinach. An aqueous solution of oxalic acid is 0.580 *m* H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>. The density of the solution is 1.022 g/mL. What is the molar concentration?

**12.64** Citric acid, H<sub>3</sub>C<sub>6</sub>H<sub>5</sub>O<sub>7</sub>, occurs in plants. Lemons contain 5% to 8% citric acid by mass. The acid is added to beverages and candy. An aqueous solution is 0.688 *m* citric acid. The density is 1.049 g/mL. What is the molar concentration?

**12.65** A solution of vinegar is 0.763 *M* acetic acid, HC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>. The density of the vinegar is 1.004 g/mL. What is the molal concentration of acetic acid?

**12.66** A beverage contains tartaric acid, H<sub>2</sub>C<sub>4</sub>H<sub>4</sub>O<sub>6</sub>, a substance obtained from grapes during wine making. If the beverage is 0.265 *M* tartaric acid, what is the molal concentration? The density of the solution is 1.016 g/mL.

### Colligative Properties

**12.67** Calculate the vapor pressure at 35°C of a solution made by dissolving 24.8 g of sucrose, C<sub>12</sub>H<sub>22</sub>O<sub>11</sub>, in 70.1 g of water. The vapor pressure of pure water at 35°C is 42.2 mmHg. What is the vapor-pressure lowering of the solution? (Sucrose is nonvolatile.)

**12.68** What is the vapor pressure at 23°C of a solution of 1.20 g of naphthalene, C<sub>10</sub>H<sub>8</sub>, in 25.6 g of benzene, C<sub>6</sub>H<sub>6</sub>? The vapor pressure of pure benzene at 23°C is 86.0 mmHg; the vapor pressure of naphthalene can be neglected. Calculate the vapor-pressure lowering of the solution.

**12.69** What is the boiling point of a solution of 0.133 g of glycerol, C<sub>3</sub>H<sub>8</sub>O<sub>3</sub>, in 20.0 g of water? What is the freezing point?

**12.70** A solution was prepared by dissolving 0.800 g of sulfur, S<sub>8</sub>, in 100.0 g of acetic acid, HC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>. Calculate the freezing point and boiling point of the solution.

**12.71** An aqueous solution of a molecular compound freezes at -0.086°C. What is the molality of the solution?

**12.72** Urea, (NH<sub>2</sub>)<sub>2</sub>CO, is dissolved in 250.0 g of water. The solution freezes at -0.085°C. How many grams of urea were dissolved to make this solution?

**12.73** A 0.0182-g sample of an unknown substance was dissolved in 2.135 g of benzene. The molality of this solution, determined by freezing-point depression, was 0.0698 *m*. What is the molecular weight of the unknown substance?

**12.74** A solution contains 0.0653 g of a compound in 8.31 g of ethanol. The molality of the solution is 0.0368 *m*. Calculate the molecular weight of the compound.

**12.75** Safrole is contained in oil of sassafras and was once used to flavor root beer. A 2.39-mg sample of safrole was dissolved in 103.0 mg of diphenyl ether. The solution had a melting point of 25.70°C. Calculate the molecular weight of safrole. The freezing point of pure diphenyl ether is 26.84°C, and the freezing-point-depression constant, *K<sub>f</sub>*, is 8.00°C/*m*.

**12.76** Butylated hydroxytoluene (BHT) is used as an anti-oxidant in processed foods. (It prevents fats and oils from becoming rancid.) A solution of 2.500 g of BHT in 100.0 g of benzene had a freezing point of 4.880°C. What is the molecular weight of BHT?

**12.77** Dextran is a polymeric carbohydrate produced by certain bacteria. It is used as a blood plasma substitute. An aqueous solution contains 0.587 g of dextran in 106 mL of solution at 21°C. It has an osmotic pressure of 1.45 mmHg. What is the average molecular weight of the dextran?

**12.78** Arginine vasopressin is a pituitary hormone. It helps regulate the amount of water in the blood by reducing the flow of urine from the kidneys. An aqueous solution containing 21.6 mg of vasopressin in 100.0 mL of solution has an osmotic pressure at 25°C of 3.70 mmHg. What is the molecular weight of the hormone?

**12.79** What is the freezing point of 0.0075 *m* aqueous calcium chloride, CaCl<sub>2</sub>? Use the formula of the salt to obtain *i*.

**12.80** What is the freezing point of 0.0088 *m* aqueous sodium phosphate, Na<sub>3</sub>PO<sub>4</sub>? Use the formula of the salt to obtain *i*.

**12.81** A 0.0140-g sample of an ionic compound with the formula Cr(NH<sub>3</sub>)<sub>5</sub>Cl<sub>3</sub> was dissolved in water to give 25.0 mL of solution at 25°C. The osmotic pressure was determined to be 119 mmHg. How many ions are obtained from each formula unit when the compound is dissolved in water?

**12.82** In a mountainous location, the boiling point of pure water is found to be 95°C. How many grams of sodium chloride must be added to 1 kg of water to bring the boiling point back to 100°C? Assume that *i* = 2.

### Colloids

**12.83** Give the type of colloid (aerosol, foam, emulsion, sol, or gel) that each of the following represents.

- |              |                    |
|--------------|--------------------|
| a rain cloud | b milk of magnesia |
| c soapsuds   | d silt in water    |

**12.84** Give the type of colloid (aerosol, foam, emulsion, sol, or gel) that each of the following represents.

- |               |                    |
|---------------|--------------------|
| a ocean spray | b beaten egg white |
| c dust cloud  | d salad dressing   |

**12.85** Arsenic(III) sulfide forms a sol with a negative charge. Which of the following ionic substances should be most effective in coagulating the sol?

- |       |                     |   |                                   |
|-------|---------------------|---|-----------------------------------|
| a KCl | b MgCl <sub>2</sub> | c Al <sub>2</sub> (SO <sub>4</sub> ) <sub>3</sub> | d Na <sub>3</sub> PO <sub>4</sub> |
|-------|---------------------|---|-----------------------------------|

**12.86** Aluminum hydroxide forms a positively charged sol. Which of the following ionic substances should be most effective in coagulating the sol?

- |        |                     |   |                                  |
|--------|---------------------|---|----------------------------------|
| a NaCl | b CaCl <sub>2</sub> | c Fe <sub>2</sub> (SO <sub>4</sub> ) <sub>3</sub> | d K <sub>3</sub> PO <sub>4</sub> |
|--------|---------------------|---|----------------------------------|

## General Problems

**Key:** These problems provide more practice but are not divided by topic or keyed to exercises. Each section ends with essay questions, each of which is color coded to refer to the *A Chemist Looks at Life Science* (pink) and *A Chemist Looks at Frontiers* (purple) chapter essay on which it is based. Odd-numbered problems and the even-numbered problems that follow are similar; answers to all odd-numbered problems except the essay questions are given in the back of the book.

**12.87** A gaseous mixture consists of 87.0 mole percent  $N_2$  and 13.0 mole percent  $O_2$  (the approximate composition of air). Suppose water is saturated with the gas mixture at  $25^\circ C$  and 1.00 atm total pressure, and then the gas is expelled from the water by heating. What is the composition in mole fractions of the gas mixture that is expelled? The solubilities of  $N_2$  and  $O_2$  at  $25^\circ C$  and 1.00 atm are 0.0175 g/L  $H_2O$  and 0.0393 g/L  $H_2O$ , respectively.

**12.88** A natural gas mixture consists of 88.0 mole percent  $CH_4$  (methane) and 12.0 mole percent  $C_2H_6$  (ethane). Suppose water is saturated with the gas mixture at  $20^\circ C$  and 1.00 atm total pressure, and the gas is then expelled from the water by heating. What is the composition in mole fractions of the gas mixture that is expelled? The solubilities of  $CH_4$  and  $C_2H_6$  at  $20^\circ C$  and 1.00 atm are 0.023 g/L  $H_2O$  and 0.059 g/L  $H_2O$ , respectively.

**12.89** An aqueous solution is 14.0% ammonium chloride,  $NH_4Cl$ , by mass. The density of the solution is 1.040 g/mL. What are the molality, mole fraction, and molarity of  $NH_4Cl$  in the solution?

**12.90** An aqueous solution is 27.0% lithium chloride,  $LiCl$ , by mass. The density of the solution is 1.127 g/mL. What are the molality, mole fraction, and molarity of  $LiCl$  in the solution?

**12.91** A 55-g sample of a gaseous fuel mixture contains 0.43 mole fraction propane,  $C_3H_8$ ; the remainder of the mixture is butane,  $C_4H_{10}$ . What are the masses of propane and butane in the sample?

**12.92** The diving atmosphere used by the U.S. Navy in its undersea Sea-Lab experiments consisted of 0.036 mole fraction  $O_2$  and 0.056 mole fraction  $N_2$ , with helium (He) making up the remainder. What are the masses of nitrogen, oxygen, and helium in a 8.32-g sample of this atmosphere?

**12.93** A liquid solution consists of 0.30 mole fraction ethylene dibromide,  $C_2H_4Br_2$ , and 0.70 mole fraction propylene dibromide,  $C_3H_6Br_2$ . Both ethylene dibromide and propylene dibromide are volatile liquids; their vapor pressures at  $85^\circ C$  are 173 mmHg and 127 mmHg, respectively. Assume that each compound follows Raoult's law in the solution. Calculate the total vapor pressure of the solution.

**12.94** What is the total vapor pressure at  $20^\circ C$  of a liquid solution containing 0.30 mole fraction benzene,  $C_6H_6$ , and 0.70 mole fraction toluene,  $C_6H_5CH_3$ ? Assume that Raoult's law holds for each component of the solution. The vapor pressure of pure benzene at  $20^\circ C$  is 75 mmHg; that of toluene at  $20^\circ C$  is 22 mmHg.

**12.95** A sample of potassium aluminum sulfate 12-hydrate,  $KAl(SO_4)_2 \cdot 12H_2O$ , containing 101.5 mg is dissolved in 1.000 L of solution. Calculate the following for the solution:

- a The molarity of  $KAl(SO_4)_2$ .
- b The molarity of  $SO_4^{2-}$ .
- c The molality of  $KAl(SO_4)_2$ , assuming that the density of the solution is 1.00 g/mL.

**12.96** A sample of aluminum sulfate 18-hydrate,  $Al_2(SO_4)_3 \cdot 18H_2O$ , containing 125.0 mg is dissolved in 1.000 L of solution. Calculate the following for the solution:

- a The molarity of  $Al_2(SO_4)_3$ .
- b The molarity of  $SO_4^{2-}$ .
- c The molality of  $Al_2(SO_4)_3$ , assuming that the density of the solution is 1.00 g/mL.

**12.97** Urea,  $(NH_2)_2CO$ , has been used to melt ice from sidewalks, because the use of salt is harmful to plants. If the saturated aqueous solution contains 41% urea by mass, what is the freezing point? (The answer will be approximate, because the equation in the text applies accurately only to dilute solutions.)

**12.98** Calcium chloride,  $CaCl_2$ , has been used to melt ice from roadways. Given that the saturated solution is 32%  $CaCl_2$  by mass, estimate the freezing point.

**12.99** The osmotic pressure of blood at  $37^\circ C$  is 7.7 atm. A solution that is given intravenously must have the same osmotic pressure as the blood. What should be the molarity of a glucose solution to give an osmotic pressure of 7.7 atm at  $37^\circ C$ ?

**12.100** Maltose,  $C_{12}H_{22}O_{11}$ , is a sugar produced by malt-ing (sprouting) grain. A solution of maltose at  $25^\circ C$  has an osmotic pressure of 5.00 atm. What is the molar concentration of maltose?

**12.101** Which aqueous solution has the lower freezing point, 0.60 *m*  $CaCl_2$  or 0.60 *m* glucose?

**12.102** Which aqueous solution has the lower boiling point, 0.10 *m*  $NaBr$  or 0.10 *m*  $CaCl_2$ ?

**12.103** Commercially, sulfuric acid is obtained as a 98% solution. If this solution is 18 *M*, what is its density? What is its molality?

**12.104** Phosphoric acid is usually obtained as an 85% phosphoric acid solution. If it is 15 *M*, what is the density of this solution? What is its molality?

**12.105** A compound of manganese, carbon, and oxygen contains 28.17% Mn and 30.80% C. When 0.125 g of this compound is dissolved in 5.38 g of cyclohexane, the solution freezes at  $5.28^\circ C$ . What is the molecular formula of this compound?

**12.106** A compound of cobalt, carbon, and oxygen contains 28.10% C and 34.47% Co. When 0.147 g of this compound is dissolved in 6.72 g of cyclohexane, the solution freezes at  $5.23^\circ C$ . What is the molecular formula of this compound?

**12.107** The carbohydrate digitoxose contains 48.64% carbon and 8.16% hydrogen. The addition of 18.0 g of this

compound to 100. g of water gives a solution that has a freezing point of  $-2.2^{\circ}\text{C}$ .

- a What is the molecular formula of the compound?
- b What is the molar mass of this compound to the nearest tenth of a gram?

**12.108** Analysis of a compound gave 39.50% C, 2.21% H, and 58.30% Cl. When 0.855 g of this solid was dissolved in 7.50 g of naphthalene, the solution had a freezing point of  $78.0^{\circ}\text{C}$ . The pure solvent freezes at  $80.0^{\circ}\text{C}$ ; its molal freezing point constant is  $6.8^{\circ}\text{C}/m$ .

- a What is the molecular formula of the compound?
- b What is its molecular weight to the nearest 0.1 g?

**12.109** Fish blood has an osmotic pressure equal to that of seawater. If seawater freezes at  $-2.3^{\circ}\text{C}$ , what is the osmotic pressure of the blood at  $20^{\circ}\text{C}$ ? To solve this problem, what assumptions must be made?

**12.110** A salt solution has an osmotic pressure of 16 atmospheres at  $22^{\circ}\text{C}$ . What is the freezing point of this solution? What assumptions must be made to solve this problem?

- **12.111** What is the difference between normal hemoglobin and the hemoglobin associated with sickle-cell anemia? How does this affect the solubility of the hemoglobin?
- **12.112** What tends to happen to the hemoglobin in a blood cell of a person who has sickle-cell anemia? How does this affect the shape and oxygen-carrying capacity of the cell?
- **12.113** How are phospholipids similar in structure to a soap molecule? What structural difference accounts for the fact that phospholipids form lipid bilayers rather than the micelles that soaps form?
- **12.114** How have chemists used these phospholipids to form “the world’s smallest test tubes”? Describe how these phospholipid vesicles might be used.

## Strategy Problems

**Key:** As noted earlier, all of the practice and general problems are matched pairs. This section is a selection of problems that are not in matched-pair format. These challenging problems require that you employ many of the concepts and strategies that were developed in the chapter. In some cases, you will have to integrate several concepts and operational skills in order to solve the problem successfully.

**12.115** Two samples of sodium chloride solutions are brought to a boil on a stove. One of the solutions boils at  $100.10^{\circ}\text{C}$  and the other at  $100.15^{\circ}\text{C}$ .

- a Which of the solutions is more concentrated?
- b Which of the solutions would have a lower freezing point?
- c If you split the solution that boils at  $100.1^{\circ}\text{C}$  into two portions, how would the boiling points of the samples compare?

Which of the following statements do you agree with regarding the determination of your answer for part c?

- i The question cannot be answered with certainty without knowing the volumes of each portion.
- ii Making the necessary assumption that the two samples have equal volumes, I was able to correctly answer the question.
- iii The volumes that the sample was split into are irrelevant when determining the correct answer.

**12.116** A sample of an ionic solid is dissolved in 1.00 kg of water. The freezing point of the water is  $-0.01^{\circ}\text{C}$ . If three times the mass of ionic solid is dissolved in 1.00 kg of water and the resulting freezing point of the solution is  $-0.09^{\circ}\text{C}$ , which of the following would be possible formulas for the solid: MX,  $\text{MX}_2$ , or  $\text{MX}_3$ , where M represents a metal cation and X an anion with a 1-charge? Explain your reasoning.

**12.117** You have an aqueous, dilute solution of a non-volatile nonelectrolyte. Assuming that the solution is ideal, choose the following statement(s) that are true.

- a If the concentration of the solute is increased, then the osmotic pressure of the solution will increase.
- b The addition of more solute will cause an increase in the boiling point of the solution.
- c The vapor pressure of this solution would decrease if some of the water were allowed to evaporate.

- d The solution will freeze at a temperature below  $0^{\circ}\text{C}$  at 1.0 atm.
- e The addition of pure water to the solution will cause the boiling point to decrease.

**12.118** Consider the three ionic compounds, NaCl, KCl, and LiCl.

- a Which compound would you expect to have the greatest lattice energy?
- b Which compound would have the greatest energy of hydration?
- c Are the three ionic compounds soluble in water?
- d What is the relationship between the lattice energy and the energy of hydration that will make an ionic compound soluble in water?

**12.119** The concentrations of pollutants are often reported as parts per million (ppm). Parts per million of a solution is defined as:

$$\text{ppm} = \frac{\text{mass of solute}}{\text{mass of solution}} \times 10^6$$

The U.S. Environmental Protection Agency (EPA) limit for barium in municipal drinking water is 2 ppm.

- a Calculate the maximum mass percentage of barium allowed in drinking water.
- b Calculate the molarity of a solution of barium that is 2 ppm. Assume that the density of the solution is  $1.00 \text{ g/mL}$ .
- c Express the concentration of barium as mg per liter.

**12.120** Which of the following ways of expressing concentration would be most likely to change with a change in temperature: molarity, molality, or mass percentage? Explain your reasoning.

**12.121** When 79.3 g of a particular compound is dissolved in 0.878 kg of water at 1 atm pressure, the solution freezes at  $-1.34^{\circ}\text{C}$ . If the compound does not undergo ionization in solution and is nonvolatile, determine the molecular weight of the compound.

**12.122** What is the boiling point of a solution made by adding 6.69 g of magnesium chloride to 250.0 g of water? Use the formula of the salt to obtain  $i$ .

**12.123** At  $15^{\circ}\text{C}$  and a partial pressure of 2.14 atm, the solubility of an unknown gas in a liquid is  $15.6 \text{ g/L}$ . What is the

solubility of the gas in the liquid when the partial pressure of the gas is 24.6 atm? What would happen to the solubility of the gas if the temperature of the liquid were increased?

**12.124** Methanol,  $\text{CH}_3\text{OH}$ , is a compound that is used in car windshield washer fluid to lower the freezing point of the solution. If an aqueous solution of windshield washer fluid has a mole fraction of methanol of 0.525, what is the mass percentage of water in this solution?

**12.125** How many grams of potassium chloride must be added to 372 g of water in order to prepare a 0.110 *m* potassium chloride solution?

**12.126** Although somewhat toxic, barium chloride has been used as a cardiac stimulant. Calculate the number of moles of barium chloride in 427 g of a 3.25% by mass barium chloride solution?

**12.127** Ethanol,  $\text{CH}_3\text{CH}_2\text{OH}$ , is known as grain alcohol and is the alcohol found in alcoholic beverages. Calculate the mole fraction of ethanol in a solution that contains 4.76 g of ethanol dissolved in 50.0 g of water.

**12.128** A starch has a molar mass of  $3.20 \times 10^4$  g/mol. If 0.759 g of this starch is dissolved in 112 mL of solution, what is the osmotic pressure, *in torr*, at 25.00°C?

**12.129** An aqueous solution is 0.797 *M* magnesium chloride. Given that the density of the solution is 1.108 g/mL, what is the molality of magnesium chloride in this solution?

**12.130** A  $\text{CaCl}_2$  solution at 25°C has an osmotic pressure of 16 atm and a density of 1.108 g/mL. What is the freezing point of this solution?

## Capstone Problems

**Key:** The problems under this heading combine skills, strategies, and concepts learned in previous chapters with those introduced in the current one

**12.131** An experimenter makes up a solution of 0.375 mol  $\text{Na}_2\text{CO}_3$ , 0.125 mol  $\text{Ca}(\text{NO}_3)_2$ , and 0.200 mol  $\text{AgNO}_3$  in 2.000 L of water solution. Note any precipitations that occur, writing a balanced equation for each. Then, calculate the molarities of each ion in the solution.

**12.132** An experimenter makes up a solution of 0.360 mol  $\text{Na}_3\text{PO}_4$ , 0.100 mol  $\text{Ca}(\text{NO}_3)_2$ , and 0.100 mol  $\text{AgNO}_3$  in 4.000 L of water solution. Note any precipitations that occur, writing a balanced equation for each. Then, calculate the molarities of each ion in the solution.

**12.133** The lattice enthalpy of sodium chloride,  $\Delta H^\circ$  for

is 787 kJ/mol; the heat of solution in making up 1 *M*  $\text{NaCl}(aq)$  is +4.0 kJ/mol. From these data, obtain the sum of the heats of hydration of  $\text{Na}^+$  and  $\text{Cl}^-$ . That is, obtain the sum of  $\Delta H^\circ$  values for

If the heat of hydration of  $\text{Cl}^-$  is -338 kJ/mol, what is the heat of hydration of  $\text{Na}^+$ ?

**12.134** The lattice enthalpy of potassium chloride is 717 kJ/mol; the heat of solution in making up 1 *M*  $\text{KCl}(aq)$  is +18.0 kJ/mol. Using the value for the heat of hydration of  $\text{Cl}^-$  given in Problem 12.133, obtain the heat of hydration of  $\text{K}^+$ . Compare this with the value you obtained for  $\text{Na}^+$  in Problem 12.133. Explain the relative values of  $\text{Na}^+$  and  $\text{K}^+$ .

**12.135** A solution is made up by dissolving 15.0 g  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$  in 140.0 g of water. What is the molality of  $\text{MgSO}_4$  in this solution?

**12.136** A solution is made up by dissolving 18.0 g  $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$  in 100.0 g of water. What is the molality of  $\text{Na}_2\text{CO}_3$  in this solution?

**12.137** An aqueous solution is 15.0% by mass of copper(II) sulfate pentahydrate,  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ . What is the molarity of  $\text{CuSO}_4$  in this solution at 20°C? The density of this solution at 20°C is 1.167 g/mL.

**12.138** An aqueous solution is 20.0% by mass of sodium thiosulfate pentahydrate,  $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ . What is the molarity of  $\text{Na}_2\text{S}_2\text{O}_3$  in this solution at 20°C? The density of this solution at 20°C is 1.174 g/mL.

**12.139** The freezing point of 0.0830 *m* aqueous acetic acid is -0.159°C. Acetic acid,  $\text{HC}_2\text{H}_3\text{O}_2$ , is partially dissociated according to the equation

Calculate the percentage of  $\text{HC}_2\text{H}_3\text{O}_2$  molecules that are dissociated, assuming the equation for the freezing-point depression holds for the total concentration of molecules and ions in the solution.

**12.140** The freezing point of 0.109 *m* aqueous formic acid is -0.210°C. Formic acid,  $\text{HCHO}_2$ , is partially dissociated according to the equation

Calculate the percentage of  $\text{HCHO}_2$  molecules that are dissociated, assuming the equation for the freezing-point depression holds for the total concentration of molecules and ions in the solution.

**12.141** A compound of carbon, hydrogen, and oxygen was burned in oxygen, and 1.000 g of the compound produced 1.434 g  $\text{CO}_2$  and 0.783 g  $\text{H}_2\text{O}$ . In another experiment, 0.1107 g of the compound was dissolved in 25.0 g of water. This solution had a freezing point of -0.0894°C. What is the molecular formula of the compound?

**12.142** A compound of carbon, hydrogen, and oxygen was burned in oxygen, and 1.000 g of the compound produced 1.418 g  $\text{CO}_2$  and 0.871 g  $\text{H}_2\text{O}$ . In another experiment, 0.1103 g of the compound was dissolved in 45.0 g of water. This solution had a freezing point of -0.0734°C. What is the molecular formula of the compound?

## Rates of Reaction

The reaction of magnesium with three different concentrations of hydrochloric acid ( $2\text{HCl}(aq) + \text{Mg}(s) \longrightarrow \text{H}_2(g) + \text{MgCl}_2(aq)$ ). As the concentration of  $\text{HCl}(aq)$  is decreased as we move from the left to the right test tube, the rate of the formation of  $\text{H}_2(g)$  decreases. This is evidence that the rate of the reaction decreases as the concentration of  $\text{HCl}(aq)$  decreases.

**Reaction time** A chemical reaction takes time. Some reactions are complete in a fraction of a second; others take years. The reaction shown here is complete in less than a minute. The reaction is the formation of a product of formaldehyde with hydrogen sulfite ion:  $\text{H}_2\text{C}=\text{O}(aq) + \text{HSO}_3^-(aq) \longrightarrow \text{H}_2\text{C}(\text{OH})\text{SO}_3^-(aq)$ . As the hydrogen sulfite ion is used up, the solution becomes less acidic and then changes to basic. Bromthymol-blue indicator marks the change from acidic to basic by changing from yellow to blue.

**C**hemical reactions require varying lengths of time for completion, depending on the characteristics of the reactants and products and the conditions under which the reaction is run (Figure 13.1). Many reactions are over in a fraction of a second, whereas others can take much longer. If you add barium ion to an aqueous solution of sulfate ion, a precipitate of barium sulfate forms almost immediately. On the other hand, the reactions that occur in a cement mixture as it hardens to concrete require years for completion.

The study of the rate, or speed, of a reaction has important applications. In the manufacture of ammonia from nitrogen and hydrogen, you may wish to know what conditions will help the reaction proceed in a commercially feasible length of time. You may also wish to know whether the nitrogen monoxide, NO, in the exhaust gases of high-altitude aircraft will destroy the ozone in the stratosphere faster than the ozone is produced. Answering these questions requires knowledge of the rates of reactions.

Another reason for studying reaction rates is to understand how chemical reactions occur. By noting how the rate of a reaction is affected by changing conditions, you can sometimes learn the details of what is happening at the molecular level.

A reaction whose rate has been extensively studied under various conditions is the decomposition of dinitrogen pentoxide,  $\text{N}_2\text{O}_5$ . When this substance is heated in the gas phase, it decomposes to nitrogen dioxide and oxygen:

We will look at this reaction in some detail. The questions we will pose include: How is the rate of a reaction like this measured? What conditions affect the rate of a reaction? How do you express the relationship of rate of a reaction to the variables that affect rate? What happens at the molecular level when  $\text{N}_2\text{O}_5$  decomposes to  $\text{NO}_2$  and  $\text{O}_2$ ?

## ▶ Reaction Rates

*Chemical kinetics* is the study of reaction rates, how reaction rates change under varying conditions, and what molecular events occur during the overall reaction. In the first part of this chapter, we will look at reaction rates and the variables that affect them.

What variables affect reaction rates? As we noted in the chapter opening, the rate depends on the characteristics of the reactants in a particular reaction. Some reactions are fast and others are slow, but the rate of any given reaction may be affected by the following factors:

1. *Concentrations of reactants.* Often the rate of reaction increases when the concentration of a reactant is increased. A piece of steel wool burns with some difficulty in air (20%  $\text{O}_2$ ) but bursts into a dazzling white flame in pure oxygen. The rate of burning increases with the concentration of  $\text{O}_2$ . In some reactions, however, the rate is unaffected by the concentration of a particular reactant, as long as it is present at some concentration.
2. *Concentration of catalyst.* A **catalyst** is a substance that increases the rate of reaction without being consumed in the overall reaction. Because the catalyst is not consumed by the reaction, it does not appear in the balanced chemical equation (although its presence may be indicated by writing its formula over the arrow). A solution of pure hydrogen peroxide,  $\text{H}_2\text{O}_2$ , is stable, but when hydrobromic acid,  $\text{HBr}(aq)$ , is added,  $\text{H}_2\text{O}_2$  decomposes rapidly into  $\text{H}_2\text{O}$  and  $\text{O}_2$  (Figure 13.2).

Here HBr acts as a catalyst to speed decomposition.

3. *Temperature at which the reaction occurs.* Usually reactions speed up when the temperature increases. It takes less time to boil an egg at sea level than on a mountaintop, where water boils at a lower temperature. Reactions during cooking go faster at higher temperature.
4. *Surface area of a solid reactant or catalyst.* If a reaction involves a solid with a gas or liquid, the surface area of the solid affects the reaction rate. Because the reaction occurs at the surface of the solid, the rate increases with increasing surface area. A wood fire burns faster if the logs are chopped into smaller pieces. Similarly, the surface area of a solid catalyst is important to the rate of reaction. The greater the surface area per unit volume, the faster the reaction (Figure 13.3).

In the first sections of this chapter, we will look primarily at reactions in the gas phase and in liquid solution where factors 1 to 3 are important. Thus, we will look at the effect of *concentrations* and *temperature* on reaction rates. Before we can explore these factors, however, we need a precise definition of reaction rate.

### 13.1 Definition of Reaction Rate

The rate of a reaction is the amount of product formed or the amount of reactant used up per unit of time. So that a rate calculation does not depend on the total quantity of reaction mixture used, you express the rate for a unit volume of the mixture. Therefore, the **reaction rate** is *the increase in molar concentration of product of a reaction per unit time or the decrease in molar concentration of reactant per unit time*. The usual unit of reaction rate is moles per liter per second, mol/(L · s).

Consider the gas-phase reaction discussed in the chapter opening:

The rate for this reaction could be found by observing the increase in molar concentration of  $\text{O}_2$  produced. You denote the molar concentration of a substance by enclosing its formula in square brackets. Thus,  $[\text{O}_2]$  is the molar concentration of  $\text{O}_2$ . In a given time interval  $\Delta t$ , the molar concentration of oxygen,  $[\text{O}_2]$ , in the reaction vessel increases by the amount  $\Delta[\text{O}_2]$ . The symbol  $\Delta$  (capital Greek delta) means “change in”; you obtain the change by subtracting the initial value from the final value. The rate of the reaction is given by

$$\text{Rate of formation of oxygen} = \frac{\Delta[\text{O}_2]}{\Delta t}$$

This equation gives the *average* rate over the time interval  $\Delta t$ . If the time interval is very short, the equation gives the *instantaneous* rate—that is, the rate at a particular

Figure 13.2 ◀

**Catalytic decomposition of hydrogen peroxide** The hydrogen peroxide decomposes rapidly when hydrobromic acid is added to an aqueous solution. One of the products is oxygen gas, which bubbles vigorously from the solution. In addition, some HBr is oxidized to  $\text{Br}_2$ , as can be seen from the red color of the liquid and vapor.

Figure 13.3 ▲

**Effect of large surface area on the rate of reaction** Lycopodium powder (from the tiny spores of a club moss) ignites easily to produce a yellow flame. The powder has a large surface area per volume and burns rapidly in air.

Figure 13.4 ▲

**The instantaneous rate of reaction** In the reaction  $2\text{N}_2\text{O}_5(\text{g}) \longrightarrow 4\text{NO}_2(\text{g}) + \text{O}_2(\text{g})$ , the concentration of  $\text{O}_2$  increases over time. You obtain the instantaneous rate at a given time from the slope of the tangent at the point on the curve corresponding to that time. In this diagram, the slope equals  $\Delta[\text{O}_2]/\Delta t$  obtained from the tangent.

In calculus, the rate at a given moment (the instantaneous rate) is given by the derivative  $d[\text{O}_2]/dt$ .

instant of time. The instantaneous rate is also the value of  $\Delta[\text{O}_2]/\Delta t$  for the tangent at a given instant (the straight line that just touches the curve of concentration versus time at a given point). See Figure 13.4. ◀

To understand the difference between average rate and instantaneous rate, it may help to think of the speed of an automobile. Speed can be defined as the rate of change of position,  $x$ ; that is, speed equals  $\Delta x/\Delta t$ , where  $\Delta x$  is the distance traveled. If an automobile travels 84 miles in 2.0 hours, the average speed over this time interval is  $84 \text{ mi}/2.0 \text{ hr} = 42 \text{ mi/hr}$ . However, at any instant during this interval, the speedometer, which registers instantaneous speed, may read more or less than 42 mi/hr. At some moment on the highway, it may read 55 mi/hr, whereas on a congested city street it may read only 20 mi/hr. The quantity  $\Delta x/\Delta t$  becomes more nearly an instantaneous speed as the time interval  $\Delta t$  is made smaller.

Figure 13.5 shows the increase in concentration of  $\text{O}_2$  during the decomposition of  $\text{N}_2\text{O}_5$ . It shows the calculation of average rates at two positions on the curve. For example, when the time changes from 600 s to 1200 s ( $\Delta t = 600 \text{ s}$ ), the  $\text{O}_2$  concentration increases by 0.0015 mol/L ( $= \Delta[\text{O}_2]$ ). Therefore, the average rate  $= \Delta[\text{O}_2]/\Delta t = (0.0015 \text{ mol/L})/600 \text{ s} = 2.5 \times 10^{-6} \text{ mol}/(\text{L} \cdot \text{s})$ . Later, during the time interval from 4200 s to 4800 s, the average rate is  $5 \times 10^{-7} \text{ mol}/(\text{L} \cdot \text{s})$ . Note that the rate decreases as the reaction proceeds.

Because the amounts of products and reactants are related by stoichiometry, any substance in the reaction can be used to express the rate of reaction. In the case of the decomposition

Figure 13.5 ►

**Calculation of the average rate** The average rate of formation of  $\text{O}_2$  during the decomposition of  $\text{N}_2\text{O}_5$  was calculated during two different time intervals. When the time changes from 600 s to 1200 s, the average rate is  $2.5 \times 10^{-6} \text{ mol}/(\text{L} \cdot \text{s})$ . Later, when the time changes from 4200 s to 4800 s, the average rate has slowed to  $5 \times 10^{-7} \text{ mol}/(\text{L} \cdot \text{s})$ . Thus, the rate of the reaction decreases as the reaction proceeds.

of  $\text{N}_2\text{O}_5$  to  $\text{NO}_2$  and  $\text{O}_2$ , we gave the rate in terms of the rate of formation of oxygen,  $\Delta[\text{O}_2]/\Delta t$ . However, you can also express it in terms of the rate of decomposition of  $\text{N}_2\text{O}_5$ .

$$\text{Rate of decomposition of } \text{N}_2\text{O}_5 = -\frac{\Delta[\text{N}_2\text{O}_5]}{\Delta t}$$

Note the negative sign. It always occurs in a rate expression for a reactant in order to indicate a decrease in concentration and to give a positive value for the rate. Thus, because  $[\text{N}_2\text{O}_5]$  decreases,  $\Delta[\text{N}_2\text{O}_5]$  is negative and  $-\Delta[\text{N}_2\text{O}_5]/\Delta t$  is positive.

The rate of decomposition of  $\text{N}_2\text{O}_5$  and the rate of formation of oxygen are easily related. Two moles of  $\text{N}_2\text{O}_5$  decompose for each mole of oxygen formed, so the rate of decomposition of  $\text{N}_2\text{O}_5$  is twice the rate of formation of oxygen. To equate the rates, you must divide the rate of decomposition of  $\text{N}_2\text{O}_5$  by 2 (its coefficient in the balanced chemical equation).

$$\text{Rate of formation of } \text{O}_2 = \frac{1}{2}(\text{rate of decomposition of } \text{N}_2\text{O}_5)$$

or

$$\frac{\Delta[\text{O}_2]}{\Delta t} = -\frac{1}{2} \frac{\Delta[\text{N}_2\text{O}_5]}{\Delta t}$$

### Example 13.1 Relating the Different Ways of Expressing Reaction Rates

#### Gaining Mastery Toolbox

##### Critical Concept 13.1

Rates of reaction can be defined in terms of the change in concentration per unit of time of any reactant or any product. For products, the reaction rate is a positive number, and for reactants, it is a negative number. The reaction stoichiometry is used to equate rates defined by different reactants and products.

##### Solution Essentials:

- Reaction rate
- Concentration (molarity)
- Molar interpretation of chemical equations

Consider the reaction of nitrogen dioxide with fluorine to give nitryl fluoride,  $\text{NO}_2\text{F}$ .

How is the rate of formation of  $\text{NO}_2\text{F}$  related to the rate of reaction of fluorine?

**Problem Strategy** We need to express the rate of this reaction in terms of concentration changes with time of the product,  $\text{NO}_2\text{F}$ , and reactant,  $\text{F}_2$ , and then relate these two rates. The rate of disappearance of reactants is expressed as a negative quantity of concentration change per some time interval. The rate of formation of products is expressed as a positive quantity of concentration change per some time interval. In order to equate rate expressions, we need to divide each by the coefficient of the corresponding substance in the chemical equation.

**Solution** You write

$$\text{Rate of formation of } \text{NO}_2\text{F} = \frac{\Delta[\text{NO}_2\text{F}]}{\Delta t}$$

and

$$\text{Rate of reaction of } \text{F}_2 = -\frac{\Delta[\text{F}_2]}{\Delta t}$$

You divide each rate by the corresponding coefficient and then equate them:

$$\frac{1}{2} \frac{\Delta[\text{NO}_2\text{F}]}{\Delta t} = -\frac{\Delta[\text{F}_2]}{\Delta t}$$

**Answer Check** When solving problems such as this, always make sure that you have expressed the rates with the correct sign: negative for reactants, positive for products.

**Exercise 13.1** For the reaction given in Example 13.1, how is the rate of formation of  $\text{NO}_2\text{F}$  related to the rate of reaction of  $\text{NO}_2$ ?

See Problems 13.39 and 13.40.

**Example 13.2** Calculating the Average Reaction Rate**Gaining Mastery Toolbox****Critical Concept 13.2**

The average rate of a chemical reaction is the change in concentration of a reactant or product over a defined time interval. The average rate of a chemical reaction decreases with time as the concentration of the reactants decrease.

**Solution Essentials:**

- Average reaction rate
- Reaction rate
- Concentration (molarity)

Calculate the average rate of decomposition of  $\text{N}_2\text{O}_5$ ,  $-\Delta[\text{N}_2\text{O}_5]/\Delta t$ , by the reaction

during the time interval from  $t = 600$  s to  $t = 1200$  s (regard all time figures as significant). Use the following data:

Time	$[\text{N}_2\text{O}_5]$
600 s	$1.24 \times 10^{-2} \text{ M}$
1200 s	$0.93 \times 10^{-2} \text{ M}$

**Problem Strategy** An average reaction rate is the change in concentration of a reactant or product over a time interval; in this case it's the rate of decomposition of the reactant  $\text{N}_2\text{O}_5$  ( $-\Delta[\text{N}_2\text{O}_5]/\Delta t$ ). The  $\Delta[\text{N}_2\text{O}_5]$  in the equation is the change in concentration of  $\text{N}_2\text{O}_5$  (final value minus initial value). The  $\Delta t$  is the time interval (final minus initial) over which the concentration change occurred.

**Solution** Average rate of decomposition of  $\text{N}_2\text{O}_5 = -\frac{\Delta[\text{N}_2\text{O}_5]}{\Delta t} =$

$$-\frac{(0.93 - 1.24) \times 10^{-2} \text{ M}}{(1200 - 600) \text{ s}} = -\frac{-0.31 \times 10^{-2} \text{ M}}{600 \text{ s}} = 5.2 \times 10^{-6} \text{ M/s}$$

Note that this rate is twice the rate of formation of  $\text{O}_2$  in the same time interval (within the experimental error of the value given in the preceding text discussion).

**Answer Check** Always make sure that your reaction rates are expressed as a positive number. If you end up with a negative rate, it is likely that you did not treat  $\Delta$  quantities as a final value minus an initial value.

**Exercise 13.2** Iodide ion is oxidized by hypochlorite ion in basic solution.

In  $1.00 \text{ M NaOH}$  at  $25^\circ\text{C}$ , the iodide-ion concentration (equal to the  $\text{ClO}^-$  concentration) at different times was as follows:

Time	$[\text{I}^-]$
2.00 s	$0.00169 \text{ M}$
8.00 s	$0.00101 \text{ M}$

Calculate the average rate of reaction of  $\text{I}^-$  during this time interval.

See Problems 13.46 and 13.47.

 **CONCEPT CHECK 13.1**

Shown here is a plot of the concentration of a reactant D versus time.

- How do the instantaneous rates at points A and B compare?
- Is the rate for this reaction constant at all points in time?

### 13.2 Experimental Determination of Rate

To obtain the rate of a reaction, you must determine the concentration of a reactant or product during the course of the reaction and the temperature of the reaction must be held constant. One way to do this for a slow reaction is to withdraw samples from the reaction vessel at various times and analyze them. The rate of the reaction of ethyl acetate with water in acidic solution was one of the first to be determined this way. ▶

This reaction is slow, so the amount of acetic acid produced is easily obtained by titration before any significant further reaction occurs.

More convenient are techniques that can continuously follow the progress of a reaction by observing the change in some physical property of the system. These physical methods are often adaptable to fast reactions as well as slow ones. For example, if a gas reaction involves a change in the number of molecules, the pressure of the system changes when the volume and temperature are held constant. By following the pressure change as the reaction proceeds, you can obtain the reaction rate. The decomposition of dinitrogen pentoxide in the gas phase, which we mentioned earlier, has been studied this way. Dinitrogen pentoxide crystals are sealed in a vessel equipped with a manometer (a pressure-measuring device; see Figure 13.6). The vessel is then plunged into a water bath at 45°C, at which temperature the solid vaporizes and the gas decomposes.

Manometer readings are taken at regular time intervals, and the pressure values are converted to partial pressures or concentrations of  $\text{N}_2\text{O}_5$ . The rates of reaction during various time intervals can be calculated as described in the previous section.

Another physical property used to follow the progress of a reaction is color, or the absorption of light by some species. Consider the reaction

The hypiodite ion,  $\text{IO}^-$ , absorbs at the blue end of the spectrum near 400 nm. The intensity of this absorption is proportional to  $[\text{IO}^-]$ , and you can use the absorption to determine the reaction rate. You can also follow the decomposition of  $\text{N}_2\text{O}_5$  from the intensity of the red-brown color of the product  $\text{NO}_2$ .

Ethyl acetate is a liquid with a fruity odor that belongs to a class of organic (carbon-containing) compounds called esters.

**Figure 13.6** ◀

**An experiment to follow the concentration of  $\text{N}_2\text{O}_5$  as the decomposition proceeds** The total pressure is measured during the reaction at 45°C. Pressure values can be related to the concentrations of  $\text{N}_2\text{O}_5$ ,  $\text{NO}_2$ , and  $\text{O}_2$  in the flask.

In these experiments, the intensity of absorption at a particular wavelength is measured by a spectrometer appropriate for the visible region of the spectrum. You are not limited to the use of visible-region spectrometers for the determination of reaction rates, however. Depending on the reaction, other types of instruments are used, including infrared (IR) and nuclear magnetic resonance (NMR) spectrometers, which are described briefly in Instrumental Methods essays in earlier chapters.

### 13.3 Dependence of Rate on Concentration

Experimentally, it has been found that a reaction rate depends on the concentrations of certain reactants as well as the concentration of catalyst, if there is one (Figure 13.7). Consider the reaction of nitrogen dioxide with fluorine to give nitryl fluoride,  $\text{NO}_2\text{F}$ .

The rate of this reaction is observed to be proportional to the concentration of nitrogen dioxide. When the concentration of nitrogen dioxide is doubled, the rate doubles. The rate is also proportional to the concentration of fluorine; doubling the concentration of fluorine also doubles the rate.

A **rate law** is an equation that relates the rate of a reaction to the concentrations of reactants (and catalyst) raised to various powers. The following equation is the rate law for the foregoing reaction:

$$\text{Rate} = k[\text{NO}_2][\text{F}_2]$$

Note that in this rate law both reactant concentrations have an exponent of 1. Here  $k$ , called the **rate constant**, is a proportionality constant in the relationship between rate and concentrations. It has a fixed value at any given temperature, but it varies with temperature. Whereas the units of rate are usually given as  $\text{mol}/(\text{L} \cdot \text{s})$ , the units of  $k$  depend on the form of the rate law. For the previous rate law,

$$k = \frac{\text{rate}}{[\text{NO}_2][\text{F}_2]}$$

Figure 13.7 ▼

Effect of reactant concentrations on rate of reaction

Time = 0 seconds

**a** Both beakers contain the same amounts of reactants: sodium thiosulfate,  $\text{Na}_2\text{S}_2\text{O}_3$ , in acidic solution and sodium arsenite,  $\text{Na}_3\text{AsO}_3$ . However, the beaker on the right contains more water and thus lower concentrations of reactants.

Time = 20 seconds

**b**  $\text{Na}_2\text{S}_2\text{O}_3$  decomposes slowly in acidic solution to yield  $\text{H}_2\text{S}$ , which reacts quickly with  $\text{Na}_3\text{AsO}_3$  to give a bright yellow precipitate of  $\text{As}_2\text{S}_3$ . The time it takes the precipitate to form depends on the decomposition rate of  $\text{Na}_2\text{S}_2\text{O}_3$ .

Time = 40 seconds

**c** Note that the precipitate forms more slowly in the solution of lower concentrations (the beaker on the right).

from which you get the following unit for  $k$ :

$$\frac{\text{mol}/(\text{L} \cdot \text{s})}{(\text{mol}/\text{L})^2} = \text{L}/(\text{mol} \cdot \text{s})$$

As a more general example, consider the reaction of substances A and B to give D and E, according to the balanced equation

You could write the rate law in the form

$$\text{Rate} = k[A]^m[B]^n[C]^p$$

The exponents  $m$ ,  $n$ , and  $p$  are frequently, but not always, integers. *They must be determined experimentally* and they cannot be obtained simply by looking at the balanced equation. For example, note that the exponents in the equation  $\text{Rate} = k[\text{NO}_2][\text{F}_2]$  have no relationship to the coefficients in the balanced equation  $2\text{NO}_2 + \text{F}_2 \longrightarrow 2\text{NO}_2\text{F}$ .

Once you know the rate law for a reaction and have found the value of the rate constant, you can calculate the rate of a reaction for any values of reactant concentrations. Keep in mind that the rate constant is dependent upon temperature. As you will see later, knowledge of the rate law is also useful in understanding how the reaction occurs at the molecular level.

### Reaction Order

You can classify a reaction by its orders. The **reaction order** with respect to a given reactant species equals *the exponent of the concentration of that species in the rate law, as determined experimentally*. For the reaction of  $\text{NO}_2$  with  $\text{F}_2$  to give  $\text{NO}_2\text{F}$ , the reaction is first order with respect to the  $\text{NO}_2$  because the exponent of  $[\text{NO}_2]$  in the rate law is 1. Similarly, the reaction is first order with respect to  $\text{F}_2$ .

The **overall order of a reaction** equals *the sum of the orders of the reactant species in the rate law*. In this example, the overall order is 2; that is, the reaction is second order overall.

Reactions display a variety of reaction orders. Some examples follow.

1. Cyclopropane,  $\text{C}_3\text{H}_6$ , has the molecular structure

When heated, the carbon ring (the triangle) opens up to give propylene,  $\text{CH}_2=\text{CHCH}_3$ . Because the compounds are isomers (different compounds with the same molecular formula), the reaction is called an *isomerization*.

The reaction has the experimentally determined rate law

$$\text{Rate} = k[\text{C}_3\text{H}_6]$$

The reaction is first order in cyclopropane and first order overall.

2. Nitrogen monoxide, NO, reacts with hydrogen according to the equation

The experimentally determined rate law is

$$\text{Rate} = k[\text{NO}]^2[\text{H}_2]$$

Thus, the reaction is second order in NO, first order in H<sub>2</sub>, and third order overall.

3. Acetone, CH<sub>3</sub>COCH<sub>3</sub>, reacts with iodine in acidic solution.

The experimentally determined rate law is

$$\text{Rate} = k[\text{CH}_3\text{COCH}_3][\text{H}^+]$$

The reaction is first order in acetone. It is zero order in iodine; that is, the rate law contains the factor [I<sub>2</sub>]<sup>0</sup> = 1. Therefore, the rate does not depend on the concentration of I<sub>2</sub>, as long as some concentration of I<sub>2</sub> is present. Note that the reaction is first order in the catalyst, H<sup>+</sup>. Thus, the overall order is 2.

Although reaction orders frequently have whole-number values (particularly 1 or 2), they can be fractional. Zero and negative orders are also possible.

### Example 13.3 Determining the Order of Reaction from the Rate Law

#### Gaining Mastery Toolbox

##### Critical Concept 13.3

For a chemical reaction, the rate law specifies the reaction order of each reactant and allows the determination of the overall order. The reactant order for each reactant is the exponent in the rate law. The overall order of the reaction is the sum of the exponents (orders) of each reactant in the rate law. Rate laws must be determined experimentally.

##### Solution Essentials:

- Overall reaction order
- Reaction order
- Rate law

Bromide ion is oxidized by bromate ion in acidic solution.

The experimentally determined rate law is

$$\text{Rate} = k[\text{Br}^-][\text{BrO}_3^-][\text{H}^+]^2$$

What is the order of reaction with respect to each reactant species? What is the overall order of the reaction?

**Problem Strategy** The exponent of each of the reactants given in the experimentally determined rate law is the reaction order of that reactant. The overall order of the reaction is the sum of the orders of the reactant species in the rate law.

**Solution** The reaction is **first order with respect to Br<sup>-</sup>** and **first order with respect to BrO<sub>3</sub><sup>-</sup>**; it is **second order with respect to H<sup>+</sup>**. The reaction is **fourth order overall** (= 1 + 1 + 2).

**Answer Check** Whenever you are determining the order of reactions or of reactant species, never rely on the stoichiometry of the reaction. You must use the experimentally determined rate law.

**Exercise 13.3** What are the reaction orders with respect to each reactant species for the following reaction?

Assume the rate law is

$$\text{Rate} = k[\text{NO}_2]^2$$

What is the overall order?

See Problems 13.47, 13.48, 13.49, and 13.50.

**CONCEPT CHECK 13.2**

Consider the reaction  $Q + R \longrightarrow S + T$  and the rate law for the reaction:

$$\text{Rate} = k[\text{Q}]^0[\text{R}]^2$$

- a** You run the reaction three times, each time starting with  $[\text{R}] = 2.0 \text{ M}$ . For each run you change the starting concentration of  $[\text{Q}]$ : run 1,  $[\text{Q}] = 0.0 \text{ M}$ ; run 2,  $[\text{Q}] = 1.0 \text{ M}$ ; run 3,  $[\text{Q}] = 2.0 \text{ M}$ . Rank the rate of the three reactions using each of these concentrations.
- b** The way the rate law is written in this problem is not typical for expressions containing reactants that are zero order in the rate law. Write the rate law in the more typical fashion.

**Determining the Rate Law**

The experimental determination of the rate law for a reaction requires that you find the order of the reaction with respect to each reactant and any catalyst. The *initial-rate method* is a simple way to obtain reaction orders. It consists of doing a series of experiments in which the initial, or starting, concentrations of reactants are varied. Then the initial rates are compared, from which the reaction orders can be deduced.

To see how this method works, again consider the reaction

You observe this reaction in two experiments. In Experiment 2, the initial concentration of  $\text{N}_2\text{O}_5$  is twice that in Experiment 1. You then note the initial rate of disappearance of  $\text{N}_2\text{O}_5$  in each case. The initial concentrations and corresponding initial rates for the two experiments are given in the following table: ▶

	<i>Initial <math>\text{N}_2\text{O}_5</math> Concentration</i>	<i>Initial Rate of Disappearance of <math>\text{N}_2\text{O}_5</math></i>
Experiment 1	$1.0 \times 10^{-2} \text{ mol/L}$	$4.8 \times 10^{-6} \text{ mol/(L}\cdot\text{s)}$
Experiment 2	$2.0 \times 10^{-2} \text{ mol/L}$	$9.6 \times 10^{-6} \text{ mol/(L}\cdot\text{s)}$

In Figure 13.4, the slope of the tangent to the curve at  $t = 0$  equals the initial rate of appearance of  $\text{O}_2$ , which equals one-half the initial rate of disappearance of  $\text{N}_2\text{O}_5$ .

The rate law for this reaction will have the concentration of reactant raised to a power  $m$ .

$$\text{Rate} = k[\text{N}_2\text{O}_5]^m$$

The value of  $m$  (the reaction order) must be determined from the experimental data. Note that when the  $\text{N}_2\text{O}_5$  concentration is doubled, you get a new rate,  $\text{Rate}'$ , given by the following equation:

$$\text{Rate}' = k(2[\text{N}_2\text{O}_5])^m = 2^m k[\text{N}_2\text{O}_5]^m$$

This rate is  $2^m$  times the original rate.

You can now see how the rate is affected when the concentration is doubled for various choices of  $m$ . Suppose  $m = 2$ . You get  $2^m = 2^2 = 4$ . That is, when the initial concentration is doubled, the rate is multiplied by 4. We summarize the results for various choices of  $m$  in Table 13.1.

**Table 13.1** Effect on Rate of Doubling the Initial Concentration of Reactant

$m$	Rate Is Multiplied by:
-1	$\frac{1}{2}$
0	1
1	2
2	4

Suppose you divide the initial rate of reaction of  $\text{N}_2\text{O}_5$  from Experiment 2 by the initial rate from Experiment 1.

$$\frac{9.6 \times 10^{-6} \text{ mol}/(\text{L} \cdot \text{s})}{4.8 \times 10^{-6} \text{ mol}/(\text{L} \cdot \text{s})} = 2.0$$

You see that when the  $\text{N}_2\text{O}_5$  concentration is doubled, the rate is doubled. This corresponds to the case  $m = 1$ . The rate law must have the form

$$\text{Rate} = k[\text{N}_2\text{O}_5]$$

You can determine the value of the rate constant  $k$  by substituting values of the rate and  $\text{N}_2\text{O}_5$  concentrations from any of the experiments into the rate law. Using values from Experiment 2, you get

$$9.6 \times 10^{-6} \text{ mol}/(\text{L} \cdot \text{s}) = k \times 2.0 \times 10^{-2} \text{ mol/L}$$

Hence,

$$k = \frac{9.6 \times 10^{-6}/\text{s}}{2.0 \times 10^{-2}} = 4.8 \times 10^{-4}/\text{s}$$

### Example 13.4 Determining the Rate Law from Initial Rates

#### Gaining Mastery Toolbox

##### Critical Concept 13.4

The rate law is a function of the concentrations of the reactants of a chemical reaction and the rate constant. The exponents of each reactant (order) in the rate law must be experimentally determined. The initial rate method is an experimental approach that allows for the determination of the rate law for a chemical reaction: the order of each reactant and the rate constant,  $k$ .

##### Solution Essentials:

- Initial rate method
- Reaction order
- Rate constant
- Rate law

Iodide ion is oxidized in acidic solution to triiodide ion,  $\text{I}_3^-$ , by hydrogen peroxide.

A series of four experiments was run at different concentrations, and the initial rates of  $\text{I}_3^-$  formation were determined (see table). a. From these data, obtain the reaction orders with respect to  $\text{H}_2\text{O}_2$ ,  $\text{I}^-$ , and  $\text{H}^+$ . b. Then find the rate constant.

	Initial Concentrations (mol/L)			Initial Rate [mol/(L·s)]
	$\text{H}_2\text{O}_2$	$\text{I}^-$	$\text{H}^+$	
Exp. 1	0.010	0.010	0.00050	$1.15 \times 10^{-6}$
Exp. 2	0.020	0.010	0.00050	$2.30 \times 10^{-6}$
Exp. 3	0.010	0.020	0.00050	$2.30 \times 10^{-6}$
Exp. 4	0.010	0.010	0.00100	$1.15 \times 10^{-6}$

#### Problem Strategy

a. In order to know the reaction orders of the reactants, you need to know the rate law. Using the reactants in the chemical equation, you assume the rate law has the following form:

$$\text{Rate} = k[\text{H}_2\text{O}_2]^m[\text{I}^-]^n[\text{H}^+]^p$$

You can determine each of the reaction orders (exponents  $m$ ,  $n$ , and  $p$ ) by choosing experiments in which all concentrations of reactants except one are held constant. Solving for each exponent will require comparing different experiments. Once you know the reaction orders, you will know the rate law. b. To determine the rate constant, you can take the data from one of the experiments and substitute them into the rate law; the only unknown in the equation will be the rate constant,  $k$ .

#### Solution

a. Comparing Experiment 1 and Experiment 2, you see that when the  $\text{H}_2\text{O}_2$  concentration is doubled (with other concentrations constant), the rate is doubled. From Table 13.1, you see that  $m = 1$ . The reaction is first order in  $\text{H}_2\text{O}_2$ .

(continued)

**Example 13.4** (continued)

To solve a problem such as this in a general way, you approach it algebraically. You write the rate law for two experiments. (The subscripts denote the experiments.)

$$(\text{Rate})_1 = k[\text{H}_2\text{O}_2]_1^m [\text{I}^-]_1^n [\text{H}^+]^p$$

$$(\text{Rate})_2 = k[\text{H}_2\text{O}_2]_2^m [\text{I}^-]_2^n [\text{H}^+]^p$$

Now you divide the second equation by the first.

$$\frac{(\text{Rate})_2}{(\text{Rate})_1} = \frac{k[\text{H}_2\text{O}_2]_2^m [\text{I}^-]_2^n [\text{H}^+]^p}{k[\text{H}_2\text{O}_2]_1^m [\text{I}^-]_1^n [\text{H}^+]^p}$$

The rate constant cancels. Grouping the terms, you obtain

$$\frac{(\text{Rate})_2}{(\text{Rate})_1} = \left( \frac{[\text{H}_2\text{O}_2]_2}{[\text{H}_2\text{O}_2]_1} \right)^m \left( \frac{[\text{I}^-]_2}{[\text{I}^-]_1} \right)^n \left( \frac{[\text{H}^+]_2}{[\text{H}^+]_1} \right)^p$$

Now you substitute values from Experiment 1 and Experiment 2. (In a ratio the units cancel and can be omitted.)

$$\frac{2.30 \times 10^{-6}}{1.15 \times 10^{-6}} = \left[ \frac{0.020}{0.010} \right]^m \left[ \frac{0.010}{0.010} \right]^n \left[ \frac{0.00050}{0.00050} \right]^p$$

This gives  $2 = 2^m$ , from which you obtain  $m = 1$ . That is, doubling the  $\text{H}_2\text{O}_2$  concentration doubles the rate.

The exponents  $n$  and  $p$  are obtained in the same way. Comparing Experiment 1 and Experiment 3, you see that doubling the  $\text{I}^-$  concentration (with the other concentrations constant) doubles the rate. Therefore,  $n = 1$  (the reaction is first order in  $\text{I}^-$ ). Finally, comparing Experiment 1 and Experiment 4, you see that doubling the  $\text{H}^+$  concentration (holding other concentrations constant) has no effect on the rate. Therefore,  $p = 0$  (the reaction is zero order in  $\text{H}^+$ ). Because  $[\text{H}^+]^0 = 1$ , the rate law is

$$\text{Rate} = k[\text{H}_2\text{O}_2][\text{I}^-]$$

The reaction orders with respect to  $\text{H}_2\text{O}_2$ ,  $\text{I}^-$ , and  $\text{H}^+$ , are **1, 1, and 0**, respectively. Note that the orders are *not* related to the coefficients of the overall equation.

b. You calculate the rate constant by substituting values from any of the experiments into the rate law. Using Experiment 1, you obtain

$$1.15 \times 10^{-6} \frac{\text{mol}}{\text{L} \cdot \text{s}} = k \times 0.010 \frac{\text{mol}}{\text{L}} \times 0.010 \frac{\text{mol}}{\text{L}}$$

$$k = \frac{1.15 \times 10^{-6} / \text{s}}{0.010 \times 0.010 \times \text{mol/L}} = 1.2 \times 10^{-2} \text{ L} / (\text{mol} \cdot \text{s})$$

**Answer Check** Although reaction orders of greater than 2 are certainly possible, they are not nearly as common as those less than or equal to 2. If you keep this fact in mind when solving problems of this type, a reaction order greater than 2 should be looked at carefully to make sure that a calculation error wasn't made.

**Exercise 13.4** The initial-rate method was applied to the decomposition of nitrogen dioxide.

It yielded the following results:

	<i>Initial NO<sub>2</sub> Concentration</i>	<i>Initial Rate of Formation of O<sub>2</sub></i>
Exp.1	0.010 mol/L	$7.1 \times 10^{-5} \text{ mol}/(\text{L} \cdot \text{s})$
Exp.2	0.020 mol/L	$28 \times 10^{-5} \text{ mol}/(\text{L} \cdot \text{s})$

Find the rate law and the value of the rate constant with respect to  $\text{O}_2$  formation.

See Problems 13.51, 13.52, 13.53, 13.54, 13.55, and 13.56.

### CONCEPT CHECK 13.3

Rate laws are not restricted to chemical systems; they are used to help describe many “everyday” events. For example, a rate law for tree growth might look something like this:

$$\text{Rate of growth} = (\text{soil type})^w(\text{temperature})^x(\text{light})^y(\text{fertilizer})^z$$

In this equation, like chemical rate equations, the exponents need to be determined by experiment. (Can you think of some other factors?)

- Say you are a famous physician trying to determine the factors that influence the rate of aging in humans. Develop a rate law, like the one above, that would take into account at least four factors that affect the rate of aging.
- Explain what you would need to do in order to determine the exponents in your rate law.
- Consider smoking to be one of the factors in your rate law. You conduct an experiment and find that a person smoking two packs of cigarettes a day quadruples ( $4\times$ ) the rate of aging over that of a one-pack-a-day smoker. Assuming that you could hold all other factors in your rate law constant, what would be the exponent of the smoking term in your rate law?

## 13.4 Change of Concentration with Time

A rate law tells you how the rate of a reaction depends on reactant concentrations at a particular moment. But often you would like to have a mathematical relationship showing how a reactant concentration changes over a period of time. Such an equation would be directly comparable to the experimental data, which are usually obtained as concentrations at various times. In addition to summarizing the experimental data, this equation would predict concentrations for all times. Using it, you could answer questions such as: How long does it take for this reaction to be 50% complete? to be 90% complete?

Moreover, as you will see, knowing exactly how the concentrations change with time for different rate laws suggests ways of plotting the experimental data on a graph. Graphical plotting provides an alternative to the initial-rate method for determining the rate law.

Using calculus, we can transform a rate law into a *mathematical relationship between concentration and time* called an **integrated rate law**. Because we will work only with the final equations, we need not go into the derivations here. We will look in some depth at first-order reactions and briefly at second-order and zero-order reactions.

### Integrated Rate Laws (Concentration—Time Equations)

**First-Order Rate Law** Let us first look at first-order rate laws. The decomposition of dinitrogen pentoxide,

has the following rate law:

$$\text{Rate} = -\frac{\Delta[\text{N}_2\text{O}_5]}{\Delta t} = k[\text{N}_2\text{O}_5]$$

Using calculus, one can show that such a first-order rate law leads to the following relationship between  $\text{N}_2\text{O}_5$  concentration and time: ◀

$$\ln \frac{[\text{N}_2\text{O}_5]_t}{[\text{N}_2\text{O}_5]_0} = -kt$$

The general derivation using calculus is as follows: Substituting  $[\text{A}]$  for  $[\text{N}_2\text{O}_5]$ , the rate law becomes

$$\frac{-d[\text{A}]}{dt} = k[\text{A}]$$

You rearrange this to give

$$\frac{-d[\text{A}]}{[\text{A}]} = k dt$$

Integrating from time = 0 to time =  $t$ ,

$$-\int_{[\text{A}]_0}^{[\text{A}]_t} \frac{d[\text{A}]}{[\text{A}]} = k \int_0^t dt$$

gives

$$-(\ln[\text{A}]_t - \ln[\text{A}]_0) = k(t - 0)$$

This can be rearranged to give the equation in the text.

Here  $[\text{N}_2\text{O}_5]_t$  is the concentration at time  $t$ , and  $[\text{N}_2\text{O}_5]_0$  is the initial concentration of  $\text{N}_2\text{O}_5$  (that is, the concentration at  $t = 0$ ). The symbol “ln” denotes the natural logarithm (base  $e = 2.718 \dots$ ).

This equation enables you to calculate the concentration of  $\text{N}_2\text{O}_5$  at any time, once you are given the initial concentration and the rate constant. Also, you can find the time it takes for the  $\text{N}_2\text{O}_5$  concentration to decrease to a particular value.

More generally, let A be a substance that reacts to give products according to the equation

where  $a$  is the stoichiometric coefficient of reactant A. Suppose that this reaction has a first-order rate law

$$\text{Rate} = -\frac{\Delta[\text{A}]}{\Delta t} = k[\text{A}]$$

Using calculus, you get the following integrated rate law equation:

$$\ln \frac{[\text{A}]_t}{[\text{A}]_0} = -kt \quad (\text{first-order integrated rate law})$$

Here  $[\text{A}]_t$  is the concentration of reactant A at time  $t$ , and  $[\text{A}]_0$  is the initial concentration. The ratio  $[\text{A}]_t/[\text{A}]_0$  is the fraction of reactant remaining at time  $t$ .

**Second-Order Rate Law** Consider the reaction

and suppose it has the second-order rate law

$$\text{Rate} = -\frac{\Delta[\text{A}]}{\Delta t} = k[\text{A}]^2$$

An example is the decomposition of nitrogen dioxide at moderately high temperatures (300°C to 400°C).

Using calculus, you can obtain the following relationship between the concentration of A and the time.

$$\frac{1}{[\text{A}]_t} = kt + \frac{1}{[\text{A}]_0} \quad (\text{second-order integrated rate law})$$

Using this equation, you can calculate the concentration of  $\text{NO}_2$  at any time during its decomposition if you know the rate constant and the initial concentration. At 330°C, the rate constant for the decomposition of  $\text{NO}_2$  is  $0.775 \text{ L}/(\text{mol} \cdot \text{s})$ . Suppose the initial concentration is  $0.0030 \text{ mol/L}$ . What is the concentration of  $\text{NO}_2$  after 645 s? By substituting into the previous equation, you get

$$\frac{1}{[\text{NO}_2]_t} = 0.775 \text{ L}/(\text{mol} \cdot \text{s}) \times 645 \text{ s} + \frac{1}{0.0030 \text{ mol/L}} = 8.3 \times 10^2 \text{ L/mol}$$

If you invert both sides of the equation, you find that  $[\text{NO}_2]_t = 0.0012 \text{ mol/L}$ . Thus, after 645 s, the concentration of  $\text{NO}_2$  decreased from  $0.0030 \text{ mol/L}$  to  $0.0012 \text{ mol/L}$ .

### Zero-Order Reactions

There are instances where reactions are zero-order. An example includes the decomposition of ethyl alcohol in the liver in the presence of the enzyme liver alcohol dehydrogenase. Once again, consider the reaction with the general form

which has a zero-order rate law of

$$\text{Rate} = k[\text{A}]^0$$

Keeping in mind that any real number raised to the zero power is 1, the expression for zero-order rate law is usually written as

$$\text{Rate} = k$$

This rate law indicates that the rate of a zero-order reaction does not change with concentration. For example, if you have a zero-order reaction

the rate of this reaction has no dependence upon the concentration of A; however, there must be some A present for the reaction to occur. Many zero-order reactions also require some minimum reactant concentration for the reaction to behave as zero-order. This is true in the case of enzyme reactions like that mentioned above as well as in reactions that are catalyzed by a metal surface, such as the decomposition reaction of  $\text{N}_2\text{O}$  in the presence of platinum metal.

As long as this reaction is run at a high enough pressure of  $\text{N}_2\text{O}$  to saturate the metal surface, it will behave as a zero-order reaction.

The relationship between concentration and time for a zero-order reaction is

$$[\text{A}]_t = -kt + [\text{A}]_0 \quad (\text{zero-order integrated rate law})$$

Below is an example of a calculation that requires an integrated rate law.

### Example 13.5 Using an Integrated Rate Law

#### Gaining Mastery Toolbox

##### Critical Concept 13.5

An integrated rate law describes mathematically how the concentration of a reactant changes with time. An integrated rate law allows one to calculate reactant concentrations at any point in time during a chemical reaction.

##### Solution Essentials:

- Integrated rate law for a first-order reaction

$$\left( \ln \frac{[\text{A}]_t}{[\text{A}]_0} = -kt \right)$$

- Integrated rate law
- Rate law
- Reaction order

The decomposition of  $\text{N}_2\text{O}_5$  to  $\text{NO}_2$  and  $\text{O}_2$  is first order, with a rate constant of  $4.80 \times 10^{-4}/\text{s}$  at  $45^\circ\text{C}$ . a. If the initial concentration is  $1.65 \times 10^{-2} \text{ mol/L}$ , what is the concentration after 825 s? b. How long would it take for the concentration of  $\text{N}_2\text{O}_5$  to decrease to  $1.00 \times 10^{-2} \text{ mol/L}$  from its initial value, given in a?

**Problem Strategy** Part a of this problem wants us to determine the concentration of a reactant ( $\text{N}_2\text{O}_5$ ) after some period of time has elapsed. Part b of the problem asks us to determine the amount of time that has elapsed for a certain change in concentration of the reactant. An integrated rate law (first-order here), which relates concentration changes to time, will enable us to complete both of these problems.

#### Solution

a. In this case, you need to use the equation relating concentration to time for a first-order reaction, which is

$$\ln \frac{[\text{A}]_t}{[\text{A}]_0} = -kt$$

Substituting the appropriate values, you get

$$\ln \frac{[\text{N}_2\text{O}_5]_t}{1.65 \times 10^{-2} \text{ mol/L}} = -4.80 \times 10^{-4}/\text{s} \times 825 \text{ s} = -0.396$$

To solve for  $[\text{N}_2\text{O}_5]_t$ , you take the antilogarithm (antiln) of both sides. This removes the ln from the left and gives  $\text{antiln}(-0.396)$ , or  $e^{-0.396}$ , on the right, which equals 0.673.

$$\frac{[\text{N}_2\text{O}_5]_t}{1.65 \times 10^{-2} \text{ mol/L}} = 0.673$$

(continued)

**Example 13.5** (continued)

Hence,

$$[\text{N}_2\text{O}_5]_t = 1.65 \times 10^{-2} \text{ mol/L} \times 0.673 = \mathbf{0.0111 \text{ mol/L}}$$

b. You substitute into the same first-order equation relating concentration to time.

$$\ln \frac{1.00 \times 10^{-2} \text{ mol/L}}{1.65 \times 10^{-2} \text{ mol/L}} = -4.80 \times 10^{-4} / \text{s} \times t$$

The left side equals  $-0.501$ ; the right side equals  $-4.80 \times 10^{-4} / \text{s} \times t$ . Hence,

$$0.501 = 4.80 \times 10^{-4} / \text{s} \times t$$

or

$$t = \frac{0.501}{4.80 \times 10^{-4} / \text{s}} = \mathbf{1.04 \times 10^3 \text{ s} \quad (17.4 \text{ min})}$$

**Answer Check** It is easy to make calculation errors when working with exponents and logarithms. Because of this, it is a good idea to check whether your final answer yields expected results when placed into a starting equation. For example, the first step of part *a* of this calculation involved the equation

$$\ln \frac{[\text{N}_2\text{O}_5]_t}{1.65 \times 10^{-2} \text{ mol/L}} = -0.396$$

If you plug the answer that you obtained for  $[\text{N}_2\text{O}_5]_t$  into the left-hand side of this equation, it should yield  $-0.396$ .

**Exercise 13.5** a. What would be the concentration of dinitrogen pentoxide in the experiment described in Example 13.5 after  $6.00 \times 10^2 \text{ s}$ ? b. How long would it take for the concentration of  $\text{N}_2\text{O}_5$  to decrease to 10.0% of its initial value?

See Problems 13.57, 13.58, 13.59, 13.60, 13.61, and 13.62.

### Half-Life of a Reaction

As a reaction proceeds, the concentration of a reactant decreases, because it is being consumed. The **half-life**,  $t_{1/2}$ , of a reaction is *the time it takes for the reactant concentration to decrease to one-half of its initial value*. ▶

For a first-order reaction, such as the decomposition of dinitrogen pentoxide, the half-life is independent of the initial concentration. To see this, substitute into the equation

$$\ln \frac{[\text{N}_2\text{O}_5]_t}{[\text{N}_2\text{O}_5]_0} = -kt$$

In one half-life, the  $\text{N}_2\text{O}_5$  concentration decreases by one-half, from its initial value,  $[\text{N}_2\text{O}_5]_0$ , to the value  $[\text{N}_2\text{O}_5]_t = \frac{1}{2}[\text{N}_2\text{O}_5]_0$ . After substituting, the equation becomes

$$\ln \frac{\frac{1}{2}[\text{N}_2\text{O}_5]_0}{[\text{N}_2\text{O}_5]_0} = -kt_{1/2}$$

The expression on the left equals  $\ln \frac{1}{2} = -0.693$ . Hence,

$$0.693 = kt_{1/2}$$

Solving for the half-life,  $t_{1/2}$ , you get

$$t_{1/2} = \frac{0.693}{k}$$

The concept of half-life is also used to characterize a radioactive nucleus, whose radioactive decay is a first-order process. This is discussed in Chapter 20.

Figure 13.8 ▲

**A graph illustrating that the half-life of a first-order reaction is independent of initial concentration**

In one half-life (1440 s, or 24.0 min), the concentration decreases by one-half, from 0.0165 mol/L to  $\frac{1}{2} \times 0.0165$  mol/L = 0.0083 mol/L. After each succeeding half-life (24.0 min), the concentration decreases by one-half again, from 0.0083 mol/L to  $\frac{1}{2} \times 0.0083$  mol/L = 0.0042 mol/L, then to  $\frac{1}{2} \times 0.0042$  mol/L = 0.0021 mol/L, and so forth.

Because the rate constant for the decomposition of  $N_2O_5$  at 45°C is  $4.80 \times 10^{-4}/s$ , the half-life is

$$t_{1/2} = \frac{0.693}{4.80 \times 10^{-4}/s} = 1.44 \times 10^3 \text{ s}$$

Thus, the half-life is  $1.44 \times 10^3$  s, or 24.0 min.

You see that the half-life of  $N_2O_5$  does not depend on the initial concentration of  $N_2O_5$ . This means that the half-life is the same at any time during the reaction. If the initial concentration is 0.0165 mol/L, after one half-life (24.0 min) the concentration decreases to  $\frac{1}{2} \times 0.0165$  mol/L = 0.0083 mol/L. After another half-life (another 24.0 min), the  $N_2O_5$  concentration decreases to  $\frac{1}{2} \times 0.0083$  mol/L = 0.0042 mol/L. Every time one half-life passes, the  $N_2O_5$  concentration decreases by one-half again (see Figure 13.8).

The foregoing result for the half-life for the first-order decomposition of  $N_2O_5$  is perfectly general. That is, for the general first-order rate law

$$\text{Rate} = -\frac{\Delta[A]}{\Delta t} = k[A]$$

the half-life is related to the rate constant but is independent of concentration of A.

$$t_{1/2} = \frac{0.693}{k} \quad (\text{first-order})$$

### Example 13.6 Relating the Half-Life of a Reaction to the Rate Constant

#### Gaining Mastery Toolbox

##### Critical Concept 13.6

The half-life of a chemical reaction is mathematically related to the rate constant. For a first-order reaction, the rate constant and half-life are independent of the reactant concentration.

##### Solution Essentials:

- Half-life
- First-order reaction half-life expression  $\left( t_{1/2} = \frac{0.693}{k} \right)$
- Rate constant

Sulfuryl chloride,  $SO_2Cl_2$ , is a colorless, corrosive liquid whose vapor decomposes in a first-order reaction to sulfur dioxide and chlorine.

At 320°C, the rate constant is  $2.20 \times 10^{-5}/s$ . a. What is the half-life of  $SO_2Cl_2$  vapor at this temperature? b. How long (in hours) would it take for 50.0% of the  $SO_2Cl_2$  to decompose? How long would it take for 75.0% of the  $SO_2Cl_2$  to decompose?

**Problem Strategy** In part a of this problem we are asked about the half-life of a first-order reaction, so a logical starting point is to use the appropriate half-life equation. For part b, consider that each half-life reduces the amount of material by 50.0%; thus two half-lives will reduce a starting amount of material by 75%, three half-lives by 87.5%, and so on.

#### Solution

$$\text{a. } t_{1/2} = \frac{0.693}{k} = \frac{0.693}{2.20 \times 10^{-5}/s} = 3.15 \times 10^4 \text{ s}$$

(continued)

**Example 13.6** (continued)

b. The half-life is the time required for one-half (50.0%) of the  $\text{SO}_2\text{Cl}_2$  to decompose. This is  $3.15 \times 10^4$  s, or **8.75 hr**. After another half-life, one-half of the remaining  $\text{SO}_2\text{Cl}_2$  decomposes. The total decomposed is  $\frac{1}{2} + (\frac{1}{2} \times \frac{1}{2}) = \frac{3}{4}$ , or 75.0%. The time required is two half-lives, or  $2 \times 8.75$  hr = **17.5 hr**.

An alternative approach is to use the integrated rate law for a first-order reaction:

$$\ln \frac{[\text{SO}_2\text{Cl}_2]_t}{[\text{SO}_2\text{Cl}_2]_0} = -kt$$

Given the data in the problem statement, we can let  $[\text{SO}_2\text{Cl}_2]_0 = 1.00$  and  $[\text{SO}_2\text{Cl}_2]_t = 0.250$  (the 0.250 represents how much would be remaining at time  $t$  after 75% of the  $\text{SO}_2\text{Cl}_2$  had decomposed). Using these values and the given rate constant, solve for  $t$ .

**Answer Check** In a problem such as this, where the initial concentration of reactant is not given, the alternative approach works *only* for first-order reactions.

**Exercise 13.6** The isomerization of cyclopropane,  $\text{C}_3\text{H}_6$ , to propylene,  $\text{CH}_2=\text{CHCH}_3$ , is first order in cyclopropane and first order overall. At  $1000^\circ\text{C}$ , the rate constant is 9.2/s. What is the half-life of cyclopropane at  $1000^\circ\text{C}$ ? How long would it take for the concentration of cyclopropane to decrease to 50% of its initial value? to 25% of its initial value?

See Problems 13.63 and 13.64.

It can be shown by reasoning similar to that given previously that the half-life of a second-order rate law,  $\text{Rate} = k[\text{A}]^2$ , is

$$t_{1/2} = \frac{1}{k[\text{A}]_0} \text{ (second-order)}$$

In this case, the half-life depends on initial concentration and each subsequent half-life becomes larger as time goes on. Consider the decomposition of  $\text{NO}_2$  at  $330^\circ\text{C}$ . It takes 430 s for the concentration to decrease by one-half from 0.0030 mol/L to 0.0015 mol/L. However, it takes 860 s (twice as long) for the concentration to decrease by one-half again. The fact that the half-life increases or changes with time is evidence that the reaction is not first order.

For zero-order reactions, the half-life is dependent upon the initial concentration of the reactant. However, in contrast to the second-order reaction, as a zero-order reaction proceeds, each half-life gets shorter.

$$t_{1/2} = \frac{[\text{A}]_0}{2k} \text{ (zero-order)}$$

### Graphing of Kinetic Data

Earlier you saw that the order of a reaction can be determined by comparing initial rates for several experiments in which different initial concentrations are used (initial-rate method). It is also possible to determine the order of a reaction by graphical plotting of the data for a particular experiment. The experimental data are plotted in several different ways, first assuming a first-order reaction, then a second-order reaction, and so forth. The order of the reaction is determined by which graph gives the best fit to the experimental data. To illustrate, we will look at how the plotting is done for first-order and second-order reactions and then compare graphs for a specific reaction.

You have seen that the first-order rate law,  $-\Delta[\text{A}]/\Delta t = k[\text{A}]$ , gives the following relationship between concentration of A and time:

$$\ln \frac{[\text{A}]_t}{[\text{A}]_0} = -kt$$

This equation can be rewritten in a slightly different form, which you can identify with the equation of a straight line. Using the property of logarithms that  $\ln(A/B) = \ln A - \ln B$ , you get

$$\ln[A]_t = -kt + \ln[A]_0$$

A straight line has the mathematical form  $y = mx + b$ , when  $y$  is plotted on the vertical axis against  $x$  on the horizontal axis. ◀ Let us now make the following identifications:

$$\begin{array}{c} \ln[A]_t = -k \quad t + \ln[A]_0 \\ \downarrow \quad \downarrow \quad \downarrow \\ y = mx + b \end{array}$$

This means that if you plot  $\ln[A]_t$  on the vertical axis against the time  $t$  on the horizontal axis, you will get a straight line for a first-order reaction. Figure 13.9 shows a plot of  $\ln[\text{N}_2\text{O}_5]$  at various times during the decomposition reaction. The fact that the points lie on a straight line is confirmation that the rate law is first order.

You can obtain the rate constant for the reaction from the slope,  $m$ , of the straight line.

$$-k = m \quad \text{or} \quad k = -m$$

You calculate the slope of this curve in the same way you obtained the average rate of reaction from kinetic data (Example 13.2). You select two points far enough apart that when you subtract to obtain  $\Delta x$  and  $\Delta y$  for the slope, you do not lose significant figures. Using the first and last points in Figure 13.9, you get

$$m = \frac{\Delta y}{\Delta x} = \frac{(-5.843) - (-4.104)}{(3600 - 0) \text{ s}} = \frac{-1.739}{3600 \text{ s}} = -4.83 \times 10^{-4}/\text{s}$$

Therefore,  $k = 4.84 \times 10^{-4}/\text{s}$ . (Two points were selected directly from the experimental data. In precise work, you would first draw the straight line that best fits the experimental data points and then calculate the slope of this line.)

The second-order rate law,  $-\Delta[A]/\Delta t = k[A]^2$ , gives the following relationship between concentration of A and time:

$$\begin{array}{c} \frac{1}{[A]_t} = kt + \frac{1}{[A]_0} \\ y = mx + b \end{array}$$

**Figure 13.9** ▶

**Plot of  $\ln[\text{N}_2\text{O}_5]$  versus time** A straight line can be drawn through the experimental points (colored dots). The fact that the straight line fits the experimental data so well confirms that the rate law is first order.

In this case, you get a straight line if you plot  $1/[A]_t$  on the vertical axis against the time  $t$  on the horizontal axis for a second-order reaction.

As an illustration of the determination of reaction order by graphical plotting, consider the following data for the decomposition of  $\text{NO}_2$  at  $330^\circ\text{C}$ .

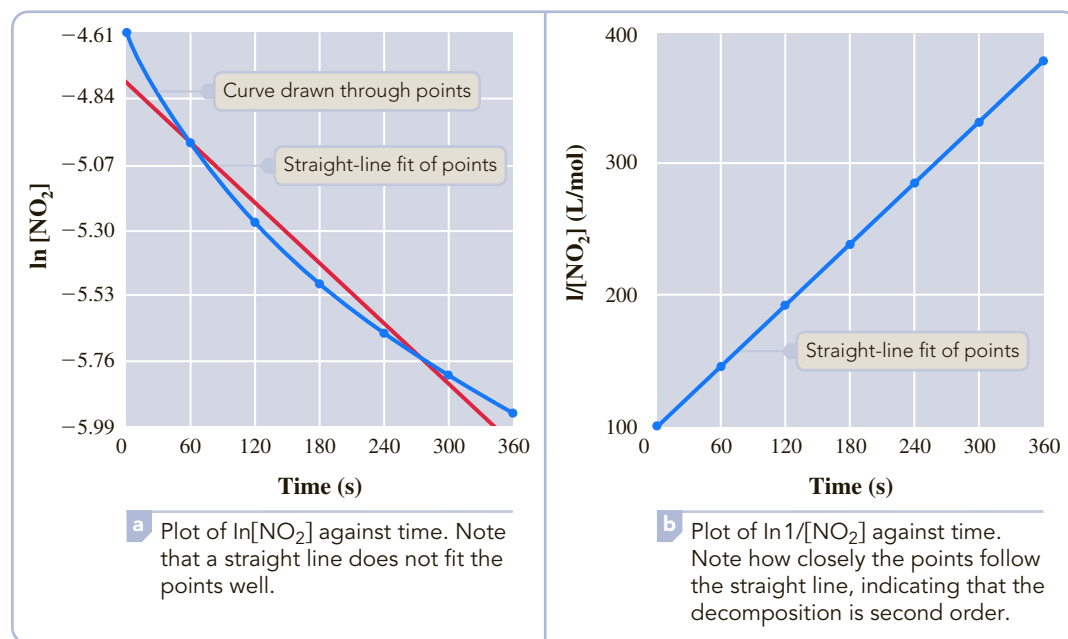

The concentrations of  $\text{NO}_2$  for various times are given in the table of data in Figure 13.10. In Figure 13.10a we have plotted  $\ln[\text{NO}_2]$  against  $t$ , and in Figure 13.10b we have plotted  $1/[\text{NO}_2]$  against  $t$ . Only in Figure 13.10b do the points closely follow a straight line, indicating that the rate law is second order. That is,

$$\text{Rate of disappearance of } \text{NO}_2 = -\frac{\Delta[\text{NO}_2]}{\Delta t} = k[\text{NO}_2]^2$$

You can obtain the rate constant,  $k$ , for a second-order reaction from the slope of the line, similar to the way you did for a first-order reaction. In this case, however, the slope equals  $k$ , as you can see from the preceding equation. Choosing the first and last points in Figure 13.10b, you get

$$k = \frac{\Delta y}{\Delta x} = \frac{(379 - 100) \text{ L/mol}}{(360 - 0) \text{ s}} = 0.775 \text{ L}/(\text{mol} \cdot \text{s})$$

**Figure 13.10** ◀  
Plotting the data for the decomposition of nitrogen dioxide at  $330^\circ\text{C}$

Time (s)	$[\text{NO}_2]$ (mol/L)	(A) $\ln [\text{NO}_2]$	(B) $1/[\text{NO}_2]$
0	$1.00 \times 10^{-2}$	-4.605	100
60	$0.683 \times 10^{-2}$	-4.984	146
120	$0.518 \times 10^{-2}$	-5.263	193
180	$0.418 \times 10^{-2}$	-5.476	239
240	$0.350 \times 10^{-2}$	-5.656	286
300	$0.301 \times 10^{-2}$	-5.805	332
360	$0.264 \times 10^{-2}$	-5.938	379

**Table 13.2** Relationships for Zero-Order, First-Order, and Second-Order Reactions

Order	Rate Law	Integrated Rate Law	Half-Life	Straight-Line Plot
0	Rate = $k$	$[A]_t = -kt + [A]_0$	$\frac{[A]_0}{2k}$	$[A]$ vs $t$
1	Rate = $k[A]$	$\ln \frac{[A]_t}{[A]_0} = -kt$	$0.693/k$	$\ln[A]$ vs $t$
2	Rate = $k[A]^2$	$\frac{1}{[A]_t} = kt + \frac{1}{[A]_0}$	$1/(k[A]_0)$	$\frac{1}{[A]}$ vs $t$

Graphical methods can also be used to determine the rate constant for zero-order reactions. Table 13.2 summarizes this and the other relationships discussed in this section for zero-order, first-order, and second-order reactions.

**✓ CONCEPT CHECK 13.4**

A reaction believed to be either first or second order has a half-life of 20 s at the beginning of the reaction but a half-life of 40 s sometime later. What is the order of the reaction?

### 13.5 Temperature and Rate; Collision and Transition-State Theories

As we noted earlier, the rate of reaction depends on temperature. This shows up in the rate law through the rate constant, which is found to vary with temperature. In most cases, the rate increases with temperature (Figure 13.11). Consider the reaction of nitrogen monoxide, NO, with chlorine, Cl<sub>2</sub>, to give nitrosyl chloride, NOCl, and chlorine atoms.

The rate constant  $k$  for this reaction is  $4.9 \times 10^{-6} \text{ L}/(\text{mol} \cdot \text{s})$  at 25°C and  $1.5 \times 10^{-5} \text{ L}/(\text{mol} \cdot \text{s})$  at 35°C. In this case the rate constant and therefore the rate are more than tripled for a 10°C rise in temperature. The change in rate constant with temperature varies considerably from one reaction to another. In many cases, the rate of reaction

**Figure 13.11** ▶  
Effect of temperature on reaction rate

**a** Each test tube contains potassium permanganate, KMnO<sub>4</sub>, and oxalic acid, H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>, at the same concentrations. Permanganate ion oxidizes oxalic acid to CO<sub>2</sub> and H<sub>2</sub>O. One test tube was placed in a beaker of warm water (40°C); the other was kept at room temperature (20°C).

**b** After 10 minutes, the test tube at 40°C (in the beaker over the burner) showed a noticeable reaction, whereas the other did not.

approximately doubles for a 10°C rise, and this is often given as an approximate rule. How do you explain this strong dependence of reaction rate on temperature? To understand it, you need to look at a simple theoretical explanation of reaction rates.

### Collision Theory

Why the rate constant depends on temperature can be explained by collision theory. **Collision theory** of reaction rates is a theory that assumes that, for reaction to occur, reactant molecules must collide with an energy greater than some minimum value and with the proper orientation. The minimum energy of collision required for two molecules to react is called the **activation energy**,  $E_a$ . The value of  $E_a$  depends on the particular reaction.

In collision theory, the rate constant for a reaction is given as a product of three factors: (1)  $Z$ , the collision frequency, (2)  $f$ , the fraction of collisions having energy greater than the activation energy, and (3)  $p$ , the fraction of collisions that occur with the reactant molecules properly oriented. Thus,

$$k = Zfp$$

We will discuss each of these factors in turn.

To have a specific reaction to relate the concepts to, consider the gas-phase reaction of NO with  $\text{Cl}_2$ , mentioned previously. This reaction is believed to occur in a single step. An NO molecule collides with a  $\text{Cl}_2$  molecule. If the collision has sufficient energy and if the molecules are properly oriented, they react to produce NOCl and Cl.

Collision frequency  $Z$ , the frequency with which the reactant molecules collide, depends on temperature. As you will see, however, this dependence of collision frequency on temperature does not explain why reaction rates usually change greatly with small temperature increases. You can easily explain why the collision frequency depends on temperature. As the temperature rises, the gas molecules move faster and therefore collide more frequently. Thus, collision frequency is proportional to the root-mean-square (rms) molecular speed, which in turn is proportional to the square root of the absolute temperature, according to the kinetic theory of gases.

► From kinetic theory, one can show that at 25°C, a 10°C rise in temperature increases the collision frequency by about 2%. If you were to assume that each collision of reactant molecules resulted in reaction, you would conclude that the rate would increase with temperature at the same rate as the collision frequency—that is, by 2% for a 10°C rise in temperature. This clearly does not explain the tripling of the rate (a 300% increase) that you see in the reaction of NO with  $\text{Cl}_2$  when the temperature is raised from 25°C to 35°C.

You see that the collision frequency varies only slowly with temperature. However,  $f$ , the fraction of molecular collisions having energy greater than the activation energy, changes rapidly in most reactions with even small temperature changes. It can be shown that  $f$  is related to the activation energy,  $E_a$ , this way:

$$f = e^{-E_a/RT}$$

Here  $e = 2.718 \dots$ , and  $R$  is the gas constant, which equals 8.31 J/(mol · K). For the reaction of NO with  $\text{Cl}_2$ , the activation energy is  $8.5 \times 10^4$  J/mol. At 25°C (298 K), the fraction of collisions with sufficient energy for reaction is  $1.2 \times 10^{-15}$ . Thus, the number of collisions of reactant molecules that actually result in reaction is extremely small. But the frequency of collisions is very large, so the reaction rate, which depends on the product of these quantities, is not small. If the temperature is raised by 10°C to 35°C, the fraction of collisions of NO and  $\text{Cl}_2$  molecules with sufficient energy for reaction is  $3.8 \times 10^{-15}$ , over three times larger than the value at 25°C! The tripling of the reaction rate is explained by the temperature dependence of  $f$ .

From the previous equation relating  $f$  to  $E_a$ , you see that  $f$  decreases with increasing values of  $E_a$ . Because the rate constant depends on  $f$ , this means that reactions with large activation energies have small rate constants and that reactions with small activation energies have large rate constants.

According to the kinetic theory of gases, the rms molecular speed equals  $\sqrt{3RT/M_m}$  (see Section 5.6).

Figure 13.12 ▶

Importance of molecular orientation in the reaction of NO and Cl<sub>2</sub>

The reaction rate also depends on  $p$ , the proper orientation of the reactant molecules when they collide. This factor is independent of temperature changes. You can see why it is important that the reactant molecules be properly oriented by looking in some detail at the reaction of NO with Cl<sub>2</sub>. Figure 13.12 shows two possible molecular collisions. In Figure 13.12a, the NO and Cl<sub>2</sub> molecules collide properly oriented for reaction. The NO molecule approaches with its N atom toward the Cl<sub>2</sub> molecule. In addition, the angle of approach is about that expected for the formation of bonds in the product molecule NOCl. In Figure 13.12b, an NO molecule approaches with its O atom toward the Cl<sub>2</sub> molecule. Because this orientation does not allow the formation of a bond between the N atom and a Cl atom, it is ineffective for reaction. The NO and Cl<sub>2</sub> molecules come together and then fly apart. All orientations except those close to that shown in (a) are ineffective.

### Transition-State Theory

Collision theory explains some important features of a reaction, but it is limited in that it does not explain the role of activation energy. **Transition-state theory** explains the reaction resulting from the collision of two molecules in terms of an activated complex. An **activated complex** (transition state) is an unstable grouping of atoms that can break up to form products. We can represent the formation of the activated complex this way:

When the molecules come together with proper orientation, an N—Cl bond begins to form. At the same time, the kinetic energy of the collision is absorbed by the activated complex as a vibrational motion of the atoms. This energy becomes concentrated in the bonds denoted by the dashed lines and can flow between them. If, at some moment, sufficient energy becomes concentrated in one of the bonds of the activated complex, that bond breaks or falls apart. Depending on whether the N—Cl or Cl—Cl bond breaks, the activated complex either reverts to the reactants or yields the products.

### Potential-Energy Diagrams for Reactions

It is instructive to consider a potential-energy diagram for the reaction of NO with  $\text{Cl}_2$ . We can represent this reaction by the equation

Here  $\text{NOCl}_2^\ddagger$  denotes the activated complex. Figure 13.13 shows the change in potential energy (indicated by the solid curve) that occurs during the progress of the reaction. The potential-energy curve starts at the left with the potential energy of the reactants,  $\text{NO} + \text{Cl}_2$ . Moving along the curve toward the right, the potential energy increases to a maximum, corresponding to the activated complex. Farther to the right, the potential energy decreases to that of the products,  $\text{NOCl} + \text{Cl}$ .

At the start, the NO and  $\text{Cl}_2$  molecules have a certain quantity of kinetic energy. The total energy of these molecules equals their potential energy plus their kinetic energy, and it remains constant throughout the reaction (according to the law of conservation of energy). As the reaction progresses (going from left to right in the diagram), the reactants come together. The potential energy increases because the outer electrons of the two molecules repel. The kinetic energy decreases, and the molecules slow down. Only if the reactant molecules have sufficient kinetic energy is it possible for the potential energy to increase to the value for the activated complex. This kinetic energy must be equal to or greater than the difference in energy between the activated complex and the reactant molecules (85 kJ/mol). The energy difference is the activation energy for the forward reaction.

At the maximum in the potential-energy curve, the reactant molecules have come together as the activated complex. When the activated complex breaks up into products, the products go to lower potential energy (by 2 kJ/mol) and gain in kinetic energy. Note that the energy of the products is higher than the energy of the reactants. The difference in energy equals the heat of reaction,  $\Delta H$ . Because the energy increases,  $\Delta H$  is positive and the reaction is endothermic.

Now look at the reverse reaction:

The activation energy is 2 kJ/mol, the difference in energy of the initial species,  $\text{NOCl} + \text{Cl}$ , and the activated complex. This is a smaller quantity than that for the forward reaction, so the rate constant for the reverse reaction is larger.

**Figure 13.13** ◀

**Potential-energy curve (not to scale) for the endothermic reaction  $\text{NO} + \text{Cl}_2 \longrightarrow \text{NOCl} + \text{Cl}$**  For NO and  $\text{Cl}_2$  to react, at least 85 kJ/mol of energy must be supplied by the collision of reactant molecules. Once the activated complex forms, it may break up to products, releasing 2 kJ/mol of energy. The difference,  $(85 - 2)$  kJ/mol = 83 kJ/mol, is the heat energy absorbed,  $\Delta H$ .

Figure 13.14 ►

**Potential-energy curve for an exothermic reaction** The energy of the reactants is higher than that of the products, so heat energy is released when the reaction goes in the forward direction.

Figure 13.14 shows the potential-energy curve for an exothermic reaction. In this case, the energy of the reactants is higher than that of the products, so heat energy is released when the reaction goes in the forward direction.

### CONCEPT CHECK 13.5

Consider the following potential-energy curves for two different reactions:

- Which reaction has a higher activation energy for the forward reaction?
- If both reactions were run at the same temperature and have the same orientation requirements to react, which one would have the larger rate constant?
- Are these reactions exothermic or endothermic?

## 13.6 Arrhenius Equation

Rate constants for most chemical reactions closely follow an equation of the form

$$k = Ae^{-E_a/RT}$$

The mathematical equation  $k = Ae^{-E_a/RT}$ , which expresses the dependence of the rate constant on temperature, is called the **Arrhenius equation**, after its formulator, the Swedish chemist Svante Arrhenius. ◀ Here  $e$  is the base of natural logarithms, 2.718 . . . ;  $E_a$  is the activation energy;  $R$  is the gas constant, 8.31 J/(K · mol); and  $T$  is the absolute temperature. The symbol  $A$  in the Arrhenius equation, which is assumed to be a constant, is called the **frequency factor**. The frequency factor is related to the frequency of collisions with proper orientation ( $pZ$ ). (The frequency factor does have a slight dependence on temperature, as you see from collision theory, but usually this can be ignored.)

It is useful to recast Arrhenius's equation in logarithmic form. Taking the natural logarithm of both sides of the Arrhenius equation gives

$$\ln k = \ln A - \frac{E_a}{RT}$$

Arrhenius published this equation in 1889 and suggested that molecules must be given enough energy to become "activated" before they could react. Collision and transition-state theories, which enlarged on this concept, were developed later (1920s and 1930s, respectively).

Let us make the following identification of symbols:

$$\ln k = \ln A + \left( \frac{-E_a}{R} \right) \left( \frac{1}{T} \right)$$

$$y = b + mx$$

This shows that if you plot  $\ln k$  against  $1/T$ , you should get a straight line. The slope of this line is  $-E_a/R$ , from which you can obtain the activation energy  $E_a$ . The intercept is  $\ln A$ . Figure 13.15 shows a plot of  $\ln k$  versus  $1/T$  for the data given in Table 13.3. It demonstrates that the points do lie on a straight line.

You can put the previous equation into a form that is useful for computation. First you write the equation for two different absolute temperatures  $T_1$  and  $T_2$ . You write  $k_1$  for the rate constant at temperature  $T_1$  and  $k_2$  for the rate constant at temperature  $T_2$ .

$$\ln k_2 = \ln A - \frac{E_a}{RT_2}$$

$$\ln k_1 = \ln A - \frac{E_a}{RT_1}$$

You eliminate  $\ln A$  by subtracting the equations.

$$\ln k_2 - \ln k_1 = -\frac{E_a}{RT_2} + \frac{E_a}{RT_1}$$

or

$$\ln \frac{k_2}{k_1} = \frac{E_a}{R} \left( \frac{1}{T_1} - \frac{1}{T_2} \right)$$

This form of the Arrhenius equation is called the two-point form. The next example illustrates the use of the two-point Arrhenius equation.

**Figure 13.15** ▲

**Plot of  $\ln k$  versus  $1/T$**  The logarithm of the rate constant for the decomposition of  $\text{N}_2\text{O}_5$  (data from Table 13.3) is plotted versus  $1/T$ . A straight line is then fitted to the points; the slope equals  $-E_a/R$ .

**Table 13.3** Rate Constant for the Decomposition of  $\text{N}_2\text{O}_5$  at Various Temperatures

Temperature ( $^{\circ}\text{C}$ )	$k$ (s)
45.0	$4.8 \times 10^{-4}$
50.0	$8.8 \times 10^{-4}$
55.0	$1.6 \times 10^{-3}$
60.0	$2.8 \times 10^{-3}$

### Example 13.7 Using the Two-point Arrhenius Equation

#### Gaining Mastery Toolbox

##### Critical Concept 13.7

As reaction temperature changes, the rate constant changes while the activation energy remains constant. The two-point form of the Arrhenius equation can be used to calculate changes in rate constants with temperature or the activation energy of a reaction.

##### Solution Essentials:

- Two-point form of the Arrhenius equation:

$$\ln \frac{k_2}{k_1} = \frac{E_a}{R} \left( \frac{1}{T_1} - \frac{1}{T_2} \right)$$

- Activation energy
- Rate constant

The rate constant for the formation of hydrogen iodide from the elements

is  $2.7 \times 10^{-4} \text{ L}/(\text{mol} \cdot \text{s})$  at 600 K and  $3.5 \times 10^{-3} \text{ L}/(\text{mol} \cdot \text{s})$  at 650 K. a. Find the activation energy  $E_a$ . b. Then calculate the rate constant at 700 K.

**Problem Strategy** a. Substitute the data given in the problem statement into the equation noted just before this example, then solve for  $E_a$ . b. Use the same equation, but substitute for  $k_1$ ,  $T_1$ ,  $T_2$ , and  $E_a$  obtained in a, and solve for  $k_2$ .

#### Solution

$$\ln \frac{3.5 \times 10^{-3}}{2.7 \times 10^{-4}} = \frac{E_a}{8.31 \text{ J}/(\text{mol} \cdot \text{K})} \left( \frac{1}{600 \text{ K}} - \frac{1}{650 \text{ K}} \right)$$

a.

$$\ln 1.30 \times 10^1 = 2.56 = \frac{E_a}{8.31 \text{ J}/\text{mol}} \times (1.28 \times 10^{-4})$$

(continued)

**Example 13.7** (continued)

Hence,

$$E_a = \frac{2.56 \times 8.31 \text{ J/mol}}{1.28 \times 10^{-4}} = \mathbf{1.66 \times 10^5 \text{ J/mol}}$$

b. Substitute  $E_a = 1.66 \times 10^5 \text{ J/mol}$  and

$$k_1 = 2.7 \times 10^{-4} \text{ L/(mol}\cdot\text{s)} \quad (T_1 = 600 \text{ K})$$

$$k_2 = \text{unknown as yet} \quad (T_2 = 700 \text{ K})$$

You get

$$\ln \frac{k_2}{2.7 \times 10^{-4} \text{ L/(mol}\cdot\text{s)}} = \frac{1.66 \times 10^5 \text{ J/mol}}{8.31 \text{ J/(mol}\cdot\text{K)}} \times \left( \frac{1}{600 \text{ K}} - \frac{1}{700 \text{ K}} \right) = 4.77$$

Taking antilogarithms,

$$\frac{k_2}{2.7 \times 10^{-4} \text{ L/(mol}\cdot\text{s)}} = e^{4.77} = 1.2 \times 10^2$$

Hence,

$$k_2 = (1.2 \times 10^2) \times (2.7 \times 10^{-4}) \text{ L/(mol}\cdot\text{s)} = \mathbf{3.2 \times 10^{-2} \text{ L/(mol}\cdot\text{s)}}$$

**Answer Check** Activation energies are typically in the range of 10–100 kJ/mol, as is true here, where the value is 166 kJ. Anything outside that range should be suspect.

**Exercise 13.7** Acetaldehyde,  $\text{CH}_3\text{CHO}$ , decomposes when heated.

The rate constant for the decomposition is  $1.05 \times 10^{-3}/(M^{1/2}\cdot s)$  at 759 K and  $2.14 \times 10^{-2}/(M^{1/2}\cdot s)$  at 836 K. What is the activation energy for this decomposition? What is the rate constant at 865 K?

See Problems 13.77, 13.78, 13.79, and 13.80.

## ► Reaction Mechanisms

A balanced chemical equation is a description of the overall result of a chemical reaction. However, what actually happens at the molecular level may be more involved than is represented by this single equation. The reaction may take place in several steps. In the next sections, we will examine some reactions and see how the rate law can give us information about these steps, or *elementary reactions*.

### 13.7 Elementary Reactions

Consider the reaction of nitrogen dioxide with carbon monoxide.

At temperatures below 500 K, this gas-phase reaction is believed to take place in two steps.

Each step, called an **elementary reaction**, is a *single molecular event, such as a collision of molecules, resulting in a reaction. The set of elementary reactions whose overall effect is given by the net chemical equation* is called the **reaction mechanism**.

According to the reaction mechanism just given, two  $\text{NO}_2$  molecules collide and react to give the product molecule  $\text{NO}$  and the reaction intermediate  $\text{NO}_3$ . A **reaction intermediate** is a species produced during a reaction that does not appear in the net equation because it reacts in a subsequent step in the mechanism. Often the reaction intermediate has a fleeting existence and cannot be isolated from the reaction mixture. The  $\text{NO}_3$  molecule is known only from its visible light spectrum. It reacts quickly with  $\text{CO}$  to give the product molecules  $\text{NO}_2$  and  $\text{CO}_2$ .

The overall chemical equation, which represents the net result of these two elementary reactions in the mechanism, is obtained by adding the steps and canceling species that occur on both sides.

### Example 13.8 Writing the Overall Chemical Equation from a Mechanism

#### Gaining Mastery Toolbox

##### Critical Concept 13.8

When added together, the elementary reactions of a mechanism yield the balanced, overall chemical equation. Each elementary reaction represents a single molecular event. The overall chemical equation does not contain reaction intermediates.

##### Solution Essentials:

- Elementary reaction
- Reaction mechanism
- Reaction intermediate

Carbon tetrachloride,  $\text{CCl}_4$ , is obtained by chlorinating methane or an incompletely chlorinated methane such as chloroform,  $\text{CHCl}_3$ . The mechanism for the gas-phase chlorination of  $\text{CHCl}_3$  is

Obtain the net, or overall, chemical equation from this mechanism.

**Problem Strategy** To obtain the overall chemical equation, we need to add up the steps of the mechanism and cancel the species that occur on both sides.

**Solution** The first step produces two  $\text{Cl}$  atoms (a reaction intermediate). One  $\text{Cl}$  atom is used in the second step and another is used in the third step. Thus all  $\text{Cl}$  atoms cancel. Similarly, the intermediate  $\text{CCl}_3$ , produced in the second step, is used up in the third step. You can cancel all  $\text{Cl}$  and  $\text{CCl}_3$  species.

**Answer Check** As a final check of the overall equation, make sure that it is balanced. If it is not balanced, you probably missed a reaction intermediate and/or canceled a species that was not a reaction intermediate.

**Exercise 13.8** The iodide ion catalyzes the decomposition of aqueous hydrogen peroxide,  $\text{H}_2\text{O}_2$ . This decomposition is believed to occur in two steps.

What is the overall equation representing this decomposition? Note that  $\text{IO}^-$  is a reaction intermediate. The iodide ion is not an intermediate; it was added to the reaction mixture.

See Problems 13.83 and 13.84.

## Molecularity

Elementary reactions are classified according to their molecularity. The **molecularity** is the number of molecules on the reactant side of an elementary reaction. A **unimolecular reaction** is an elementary reaction that involves one reactant molecule; a **bimolecular reaction** is an elementary reaction that involves two reactant molecules. Bimolecular reactions are the most common. Unimolecular reactions are best illustrated by decomposition of some previously excited species. Some gas-phase reactions are thought to occur in a **termolecular reaction**, an elementary reaction that involves three reactant molecules. Higher molecularities are not encountered, presumably because the chance of the correct four molecules coming together at once is extremely small.

As an example of a unimolecular reaction, consider the elementary process in which an energetically excited ozone molecule (symbolized by  $O_3^*$ ) spontaneously decomposes.

Normally, a molecule in a sample of ozone gas is in a lower energy level. But such a molecule may be excited to a higher level if it collides with another molecule or absorbs a photon. The energy of the excited molecule is distributed among its three nuclei as vibrational energy. After a period of time, this energy becomes redistributed. If by chance most of the energy finds its way to one end oxygen atom, that atom will fly off. In other words, the excited ozone molecule decomposes into an oxygen molecule and an oxygen atom.

All of the steps in the mechanism of the reaction of  $NO_2$  with  $CO$ , given earlier in this section, are bimolecular. Consider the first step, which involves the reaction of two  $NO_2$  molecules.

When these two  $NO_2$  molecules come together, they form an activated complex of the six atoms,  $(NO_2)_2$ , which immediately breaks into two new molecules,  $NO_3$  and  $NO$ .

The overall reaction of two atoms—say, two  $Br$  atoms—to form a diatomic molecule ( $Br_2$ ) is normally a termolecular process. When two bromine atoms collide, they form an excited bromine molecule,  $Br_2^*$ . This excited molecule immediately flies apart, re-forming the atoms, unless another atom or molecule is present just at the moment of molecule formation to take away the excess energy. Suppose an argon atom and the two bromine atoms all collide at the same moment.

Energy that would have been left with the bromine molecule is now picked up by the argon atom (giving the energized atom  $Ar^*$ ). The bromine molecule is stabilized by being left in a lower energy level.

### Example 13.9 Determining the Molecularity of an Elementary Reaction

Copyright 2011 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

#### Gaining Mastery Toolbox

##### Critical Concept 13.9

Counting the number of molecules that are reactants in an elementary reaction defines the molecularity of the reaction.

One reactant is unimolecular, two reactants bimolecular, and three reactants termolecular.

##### Solution Essentials:

- Molecularity
- Unimolecular reaction
- Bimolecular reaction
- Termolecular reaction
- Elementary reaction
- Reaction mechanism

What is the molecularity of each step in the mechanism described in Example 13.8?

**Problem Strategy** The molecularity of any elementary reaction equals the number of reactant molecules.

**Solution** Counting the reactant molecules, the forward part of the first step is **unimolecular**; the reverse of the first step, the second step, and the third step are each **bimolecular**.

(continued)

**Example 13.9** (continued)

**Answer Check** If you end up with a molecularity of a reaction greater than 3, you have made a mistake.

**Exercise 13.9** The following is an elementary reaction that occurs in the decomposition of ozone in the stratosphere by nitrogen monoxide.

What is the molecularity of this reaction? That is, is the reaction unimolecular, bimolecular, or termolecular?

See Problems 13.85 and 13.86.

**Rate Equation for an Elementary Reaction**

There is no necessarily simple relationship between the overall reaction and the rate law that you observe for it. As we stressed before, the rate law must be obtained experimentally. However, when you are dealing with an elementary reaction, the rate does have a simple, predictable form.

For an elementary reaction, the rate is proportional to the product of the concentration of each reactant molecule.

To understand this, let us look at the different possibilities. Consider the unimolecular elementary reaction

For each A molecule there is a definite probability, or chance, that it will decompose into B and C molecules. The more A molecules there are in a given volume, the more A molecules that can decompose in that volume per unit time. In other words, the rate of reaction is proportional to the concentration of A.

$$\text{Rate} = k[\text{A}]$$

Now consider a bimolecular elementary reaction, such as

For the reaction to occur, the reactant molecules A and B must collide. Reaction does not occur with every collision. Nevertheless, the rate of formation of product is proportional to the frequency of molecular collisions, because a definite fraction of the collisions produces reaction. Within a given volume, the frequency of collisions is proportional to the number of A molecules,  $n_A$ , times the number of B molecules,  $n_B$ . Furthermore, the concentration of A is proportional to  $n_A$ , and the concentration of B is proportional to  $n_B$ . Therefore, the rate of this elementary reaction is proportional to  $[\text{A}][\text{B}]$ .

$$\text{Rate} = k[\text{A}][\text{B}]$$

A termolecular elementary reaction has a rate equation that is obtained by similar reasoning. For the elementary reaction

the rate is proportional to the concentrations of A, B, and C.

$$\text{Rate} = k[\text{A}][\text{B}][\text{C}]$$

Any reaction you observe is likely to consist of several elementary steps, and the rate law that you find is the combined result of these steps. This is why you cannot predict the rate law by looking at the overall equation.

**Example 13.10** Writing the Rate Equation for an Elementary Reaction**Gaining Mastery Toolbox****Critical Concept 13.10**

If the overall reaction is an elementary reaction, then the rate law can be written directly from the overall reaction. This is a special case; it is the *only* instance in which the rate law can be written from the overall reaction. Otherwise, one can never assume that the rate law can be written from the overall chemical equation.

**Solution Essentials:**

- Elementary reaction
- Reaction mechanism
- Rate law

Write rate equations for each of the following elementary reactions.

- a. Ozone is converted to O<sub>2</sub> by NO in a single step.

- b. The recombination of iodine atoms occurs as follows:

where M is some atom or molecule that absorbs energy from the reaction.

- c. An H<sub>2</sub>O molecule absorbs energy; some time later enough of this energy flows into one O—H bond to break it.

**Problem Strategy** The rate equation can be written directly from the elementary reaction (but *only* for an elementary reaction).

**Solution**

a. **Rate** =  $k[\text{O}_3][\text{NO}]$

b. **Rate** =  $k[\text{I}]^2[\text{M}]$

c. **Rate** =  $k[\text{H}_2\text{O}]$

**Answer Check** Keep in mind that writing the rate equation of the reaction works *only* for an elementary reaction.

**Exercise 13.10** Write the rate equation, showing the dependence of rate on concentrations, for the elementary reaction

See Problems 13.87 and 13.88.

In the next section, we look at the relationship between a reaction mechanism and the observed rate law.

**13.8 The Rate Law and the Mechanism**

The mechanism of a reaction cannot be observed directly. A mechanism is devised to explain the experimental observations. It is like the explanation provided by a detective to explain a crime in terms of the clues found. Other explanations may be possible, and further clues may make one of these other explanations seem more plausible than the currently accepted one. So it is with reaction mechanisms. They are accepted provisionally, with the understanding that further experiments may lead you to accept another mechanism as the more probable explanation. ◀

An important clue in understanding the mechanism of a reaction is the rate law. The reason for its importance is that once you assume a mechanism, you can predict the rate law. If this prediction does not agree with the experimental rate law, the assumed mechanism must be wrong. Take, for example, the overall equation

If you follow the rate of disappearance of F<sub>2</sub>, you observe that it is directly proportional to the concentration of NO<sub>2</sub> and F<sub>2</sub>.

$$\text{Rate} = k[\text{NO}_2][\text{F}_2] \quad (\text{experimental rate law})$$

This rate law is a summary of the experimental data. Assume that the reaction occurs in a single elementary reaction.

You see the scientific method in operation here, which recalls the discussion in Chapter 1. Experiments have been made from which you determine the rate law. Then a mechanism is devised to explain the rate law. This mechanism in turn suggests more experiments. These may confirm the explanation or may disagree with it. If they disagree, a new mechanism must be devised that explains all of the experimental evidence.

This, then, is your assumed mechanism. Because this is an elementary reaction, you can immediately write the rate law predicted by it.

$$\text{Rate} = k[\text{NO}_2]^2[\text{F}_2] \quad (\text{predicted rate law})$$

However, this does not agree with experiment, and your assumed mechanism must be discarded. You conclude that the reaction occurs in more than one step.

### Rate-Determining Step

The reaction of  $\text{NO}_2$  with  $\text{F}_2$  is believed to occur in the following steps (elementary reactions).

The rate constant for each step has been written over the arrow. The net result of the mechanism must be equivalent to the net result of the overall equation. By adding the two steps together, you can see that this is the case.

The F atom is a reaction intermediate.

The mechanism must also be in agreement with the experimental rate law. Let us look at that. Note that the second step is assumed to be much faster than the first, so that as soon as  $\text{NO}_2$  and  $\text{F}_2$  react, the F atom that is formed reacts with an  $\text{NO}_2$  molecule to give another  $\text{NO}_2\text{F}$  molecule. Therefore, the rate of disappearance of  $\text{F}_2$  (and therefore the rate law) is determined completely by the slow step, or rate-determining step. The **rate-determining step** is *the slowest step in the reaction mechanism*.

To understand better the significance of the rate-determining step, suppose you and a friend want to start a study group. You and your friend decide to send invitation cards to some students in your class. You write a lengthy note on each card explaining the study group, taking an average of 2.0 minutes per card. Your friend puts the card in an envelope, affixes a computer-printed address label, seals the envelope, and stamps it, taking 0.5 minute per card. How long does it take to do 100 cards? What is the average time taken per card (*rate* of completing the cards)?

Because you take longer than your friend to do each card, your friend can complete the task for one card while you are working on another. It takes you a total of (100 cards  $\times$  2.0 min/card) to do your step in the task. When you have finished the last card, your friend still has to place the card in the envelope, and so forth. Therefore, you have to add an additional 0.5 min to the total time.

$$\begin{aligned} \text{Total time for 100 cards} &= (100 \text{ cards} \times \underline{2.0} \text{ min/card}) + \underline{0.5} \text{ min} \\ &= \underline{200.5} \text{ min} \end{aligned}$$

We have underlined the last significant figure.

The rate of completing the invitation cards is

$$\text{Rate} = \underline{200.5} \text{ min}/100 \text{ cards} = 2.0 \text{ min/card}$$

The rate is essentially the time it takes you to compose a note. The time for your friend to finish the task is insignificant compared with the total time. The rate for the task equals the rate for the slower step (the rate-determining step).

The rate-determining step in the reaction of  $\text{NO}_2$  and  $\text{F}_2$  is the first step in the mechanism, in which  $\text{NO}_2$  reacts with  $\text{F}_2$  to produce  $\text{NO}_2\text{F}$  and an F atom. The rate equation for this rate-determining step of the mechanism is

$$\text{Rate} = k_1[\text{NO}_2][\text{F}_2]$$

This should equal the experimental rate law (otherwise the mechanism cannot be correct), which it does if you equate  $k_1$  to  $k$  (the experimental rate constant). This agreement is not absolute evidence that the mechanism is correct. However, one can perform experiments to see whether fluorine atoms react very quickly with nitrogen dioxide. Such experiments show that they do.

### Example 13.11 Determining the Rate Law from a Mechanism with an Initial Slow Step

#### Gaining Mastery Toolbox

##### Critical Concept 13.11

If a reaction mechanism consists of a slow first step and a fast second step, the rate law is written based only on the slow first step. In this instance, the first step in the mechanism is the rate-determining step.

##### Solution Essentials:

- Rate-determining step
- Reaction mechanism
- Rate law

Ozone reacts with nitrogen dioxide to produce oxygen and dinitrogen pentoxide.

The proposed mechanism is

What is the rate law predicted by this mechanism?

**Problem Strategy** Consider the mechanism of the reaction and look to see whether the first step is slow compared to the other steps. If this is the case, then the rate law can be written on the basis of this first step.

**Solution** The rate law from the first step is

$$\text{Rate} = k[\text{O}_3][\text{NO}_2]$$

**Answer Check** Keep in mind that writing the rate law as we have done in this problem works when the first step of the mechanism is much slower than the other steps. Reaction mechanisms that are not structured like this one will require different approaches to determine the mechanism.

**Exercise 13.11** The iodide-ion-catalyzed decomposition of hydrogen peroxide,  $\text{H}_2\text{O}_2$ , is believed to follow the mechanism

What rate law is predicted by this mechanism? Explain.

See Problems 13.89 and 13.90.

### Mechanisms with an Initial Fast Step

A somewhat more complicated situation occurs when the rate-determining step follows an initial fast, equilibrium step. The decomposition of dinitrogen pentoxide,

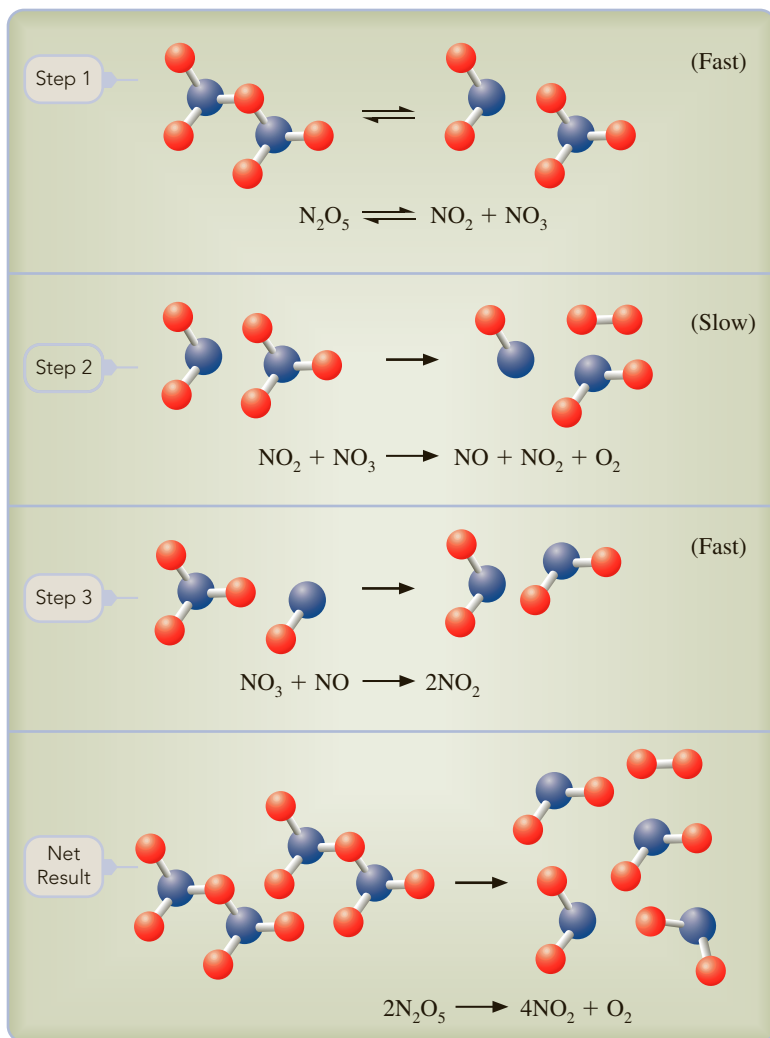

which we discussed in the chapter opening section, is believed to follow this type of mechanism.

To give the overall stoichiometry, you need to multiply the first step by two. Note that there are two reaction intermediates,  $\text{NO}_3$  and  $\text{NO}$ . Figure 13.16 represents the

**Figure 13.16** ◀

**Representation of the mechanism of decomposition of  $\text{N}_2\text{O}_5$ , using molecular models** Note that little atomic rearrangement occurs during each step.

mechanism by means of molecular models. Let us show that this mechanism is consistent with the experimentally determined rate law,

$$\text{Rate} = k[\text{N}_2\text{O}_5]$$

The second step in the mechanism is assumed to be much slower than the other steps and is therefore rate-determining. Hence, the rate law predicted from this mechanism is

$$\text{Rate} = k_2[\text{NO}_2][\text{NO}_3]$$

However, this equation cannot be compared directly with experiment because it is written in terms of the reaction intermediate,  $\text{NO}_3$ . The experimental rate law will be written in terms of substances that occur in the chemical equation, not of reaction intermediates. For purposes of comparison, it is necessary to re-express the rate equation, eliminating  $[\text{NO}_3]$ . To do this, you must look at the first step in the mechanism.

This step is fast and reversible. That is,  $\text{N}_2\text{O}_5$  dissociates rapidly into  $\text{NO}_2$  and  $\text{NO}_3$ , and these products in turn react to re-form  $\text{N}_2\text{O}_5$ . The rate of the forward reaction (dissociation of  $\text{N}_2\text{O}_5$ ) is

$$\text{Forward rate} = k_1[\text{N}_2\text{O}_5]$$

and the rate of the reverse reaction (formation of  $\text{N}_2\text{O}_5$  from  $\text{NO}_2$  and  $\text{NO}_3$ ) is

$$\text{Reverse rate} = k_{-1}[\text{NO}_2][\text{NO}_3]$$

When the reaction first begins, there are no  $\text{NO}_2$  or  $\text{NO}_3$  molecules, and the reverse rate is zero. But as  $\text{N}_2\text{O}_5$  dissociates, the concentration of  $\text{N}_2\text{O}_5$  decreases and the concentrations of  $\text{NO}_2$  and  $\text{NO}_3$  increase. Therefore, the forward rate decreases and the reverse rate increases. Soon the two rates become equal, such that  $\text{N}_2\text{O}_5$  molecules form as often as other  $\text{N}_2\text{O}_5$  molecules dissociate. The first step has reached *dynamic equilibrium*. Because these elementary reactions are much faster than the second step, this equilibrium is reached before any significant reaction by the second step occurs. Moreover, this equilibrium is maintained throughout the reaction. ◀

At equilibrium, the forward and reverse rates are equal, so you can write

$$k_1[\text{N}_2\text{O}_5] = k_{-1}[\text{NO}_2][\text{NO}_3]$$

$$[\text{NO}_3] = \frac{k_1}{k_{-1}} \frac{[\text{N}_2\text{O}_5]}{[\text{NO}_2]}$$

Substituting into the rate law, you get

$$\text{Rate} = k_2[\text{NO}_2][\text{NO}_3] = k_2[\text{NO}_2] \times \frac{k_1}{k_{-1}} \frac{[\text{N}_2\text{O}_5]}{[\text{NO}_2]}$$

or

$$\text{Rate} = k_2 \frac{k_1}{k_{-1}} [\text{N}_2\text{O}_5]$$

Thus, if you identify  $k_1 k_2 / k_{-1}$  as  $k$ , you reproduce the experimental rate law.

In addition to correctly predicting the experimental rate law, the mechanism must also be in agreement with the overall equation for the reaction. Although the first step is essentially in equilibrium, the products of this step ( $\text{NO}_2$  and  $\text{NO}_3$ ) are being continuously used in the subsequent steps. Note that each of these subsequent steps uses up a molecule of  $\text{NO}_3$ . For these steps to proceed, the first step must effectively produce two molecules of  $\text{NO}_3$ . Thus, the net result of the mechanism is as follows:

The net result of the mechanism is equivalent to the overall equation for the reaction, as it should be.

### Example 13.12 Determining the Rate Law from a Mechanism with an Initial Fast, Equilibrium Step

#### Gaining Mastery Toolbox

##### Critical Concept 13.12

If a reaction mechanism consists of a fast, equilibrium first step and a slow second step, the rate law will be based on the second slow step. The final rate law, derived from the rate-determining (slow) step, must be expressed in terms of only the concentrations of reactants present in the overall equation.

##### Solution Essentials:

- Fast, equilibrium step
- Reaction mechanism
- Rate-determining step
- Rate law

Nitrogen monoxide can be reduced with hydrogen gas to give nitrogen and water vapor.

A proposed mechanism is

What rate law is predicted by this mechanism?

**Problem Strategy** Examining the reaction mechanism, you can see that it has an initial fast, equilibrium step, followed by a slow step. You write the rate equation for the rate-determining (slow) step, just as in the previous example. In this case, however, the equation contains a species,  $\text{N}_2\text{O}_2$ , that does not appear in the overall equation for the reaction. You need to eliminate it from the final form of the rate law. Note that the first step is fast and reaches equilibrium. You use this fact to write an expression for  $[\text{N}_2\text{O}_2]$ . Then you substitute this expression for  $[\text{N}_2\text{O}_2]$  into the rate equation.

(continued)

Chemical equilibrium is discussed in detail in the next chapter.

**Example 13.12** (continued)**Solution** According to the rate-determining step,

$$\text{Rate} = k_2[\text{N}_2\text{O}_2][\text{H}_2]$$

You try to eliminate  $\text{N}_2\text{O}_2$  from the rate law by looking at the first step, which is fast and reaches equilibrium. At equilibrium, the forward rate and the reverse rate are equal.

$$k_1[\text{NO}]^2 = k_{-1}[\text{N}_2\text{O}_2]$$

Therefore,  $[\text{N}_2\text{O}_2] = (k_1/k_{-1})[\text{NO}]^2$ , so

$$\text{Rate} = \frac{k_2k_1}{k_{-1}}[\text{NO}]^2[\text{H}_2]$$

Experimentally, you should observe the rate law

$$\text{Rate} = k[\text{NO}]^2[\text{H}_2]$$

where we have replaced the constants  $k_2k_1/k_{-1}$  with  $k$ , which represents the experimentally observed rate constant.

**Answer Check** Always examine your answer to make certain that the rate law is expressed in terms of the concentrations of the reactants in the overall equation. However, keep in mind that the exponents do not necessarily reflect the stoichiometry of the overall equation.

**Exercise 13.12** Nitrogen monoxide, NO, reacts with oxygen to produce nitrogen dioxide.

If the mechanism is

what is the predicted rate law? Remember to express this in terms of substances in the chemical equation.

See Problems 13.91 and 13.92.

**CONCEPT CHECK 13.6**

You are a chemist in charge of a research laboratory that is trying to increase the reaction rate for the balanced chemical reaction

**a** One of your researchers comes into your office and states that she has found a material that significantly lowers the activation energy of the reaction. Explain the effect this will have on the rate of the reaction.

**b** Another researcher states that, after doing some experiments, he has determined that the rate law is

$$\text{Rate} = k[\text{X}][\text{Y}]$$

Is this possible?

**c** Yet another person in the lab reports that the mechanism for the reaction is:

Is the rate law from part *b* consistent with this mechanism? If not, what should the rate law be?

### 13.9 Catalysis

A catalyst is a substance that has the seemingly miraculous power of speeding up a reaction without being consumed by it. In theory, you could add a catalyst to a reaction mixture and, after the reaction, separate that catalyst and use it over and over again. In practice, there is often some loss of catalyst through other reactions that can occur at the same time. **Catalysis** is the increase in rate of a reaction that results from the addition of a catalyst.

Catalysts are of enormous importance to the chemical industry, because they allow a reaction to occur with a reasonable rate at a much lower temperature than otherwise; lower temperatures translate into lower energy costs. Moreover, catalysts are often quite specific—they increase the rate of certain reactions, but not others. For instance, an industrial chemist can start with a mixture of carbon monoxide and hydrogen and produce methane gas using one catalyst or produce gasoline using another catalyst. The most remarkable catalysts are enzymes. *Enzymes* are the marvelously selective catalysts employed by biological organisms. A biological cell contains thousands of different enzymes that in effect direct all of the chemical processes that occur in the cell.

How can we explain how a catalyst can influence a reaction without being consumed by it? Briefly, the catalyst must participate in at least one step of a reaction and be regenerated in a later step. Consider the commercial preparation of sulfuric acid,  $\text{H}_2\text{SO}_4$ , from sulfur dioxide,  $\text{SO}_2$ . The first step involves the reaction of  $\text{SO}_2$  with  $\text{O}_2$  to produce sulfur trioxide,  $\text{SO}_3$ . For this reaction to occur at an economical rate, it requires a catalyst. An early industrial process employed nitrogen monoxide,  $\text{NO}$ , as the catalyst.

Nitrogen monoxide does not appear in the overall equation but must participate in the reaction mechanism. Here is a proposed mechanism:

To obtain the overall reaction, the last step must occur twice each time the first step occurs once. As you can see from the mechanism, two molecules of  $\text{NO}$  are used up in the first step and are regenerated in the second step.

Note that the catalyst is an active participant in the reaction. But how does this participation explain the increase in speed of the catalyzed reaction over the uncatalyzed reaction? The Arrhenius equation (given at the beginning of Section 13.6) provides an answer. The catalyzed reaction mechanism makes available a reaction path having an increased overall rate of reaction. It increases this rate either by increasing the frequency factor  $A$  or, more commonly, by decreasing the activation energy  $E_a$ . The most dramatic effect comes from decreasing the activation energy, because it occurs as an exponent in the Arrhenius equation.

The depletion of ozone in the stratosphere by  $\text{Cl}$  atoms provides an example of the lowering of activation energy by a catalyst. Ozone is normally present in the stratosphere and provides protection against biologically destructive, short-wavelength ultraviolet radiation from the sun. Some recent ozone depletion in the stratosphere is believed to result from the  $\text{Cl}$ -catalyzed decomposition of  $\text{O}_3$ .  $\text{Cl}$  atoms in the stratosphere originate from the decomposition of chlorofluorocarbons (CFCs), which are compounds manufactured as refrigerants, aerosol propellants, and so forth. These  $\text{Cl}$  atoms react with ozone to form  $\text{ClO}$  and  $\text{O}_2$ , and the  $\text{ClO}$  reacts with  $\text{O}$  atoms (normally in the stratosphere) to produce  $\text{Cl}$  and  $\text{O}_2$ .

The net result is the decomposition of ozone with  $\text{O}$  atoms to produce  $\text{O}_2$ . Figure 13.17 shows the potential-energy curves for the uncatalyzed and the catalyzed reactions. The uncatalyzed reaction has such a large activation energy that its rate is

extremely low. The addition of chlorine atoms provides an alternative pathway to the same overall reaction, but has a much lower activation energy and therefore an increased rate. ▶

### Homogeneous Catalysis

The oxidation of sulfur dioxide using nitrogen monoxide as a catalyst is an example of **homogeneous catalysis**, which is *the use of a catalyst in the same phase as the reacting species*. The catalyst NO and the reacting species SO<sub>2</sub> and O<sub>2</sub> are all in the gas phase. Another example occurs in the oxidation of thallium(I) to thallium(III) by cerium(IV) in aqueous solution.

The uncatalyzed reaction is very slow; presumably it involves the collision of three positive ions. The reaction can be catalyzed by manganese(II) ion, however. The mechanism is thought to be

Each step is bimolecular.

A striking example of a homogeneous catalyst increasing the rate of a reaction is the decomposition of aqueous hydrogen peroxide to form water and oxygen.

Under standard conditions without a catalyst, this reaction is very slow, so slow in fact that when you observe a solution of hydrogen peroxide, you cannot visibly detect the reaction. However, when a solution containing aqueous potassium iodide is added to hydrogen peroxide, the rate of the reaction increases dramatically (see Figure 13.18). In this reaction, the aqueous iodide anion is the homogeneous catalyst. The proposed mechanism for the most important reaction in the solution is

### Heterogeneous Catalysis

Some of the most important industrial reactions involve **heterogeneous catalysis**—that is, *the use of a catalyst that exists in a different phase from the reacting species, usually a solid catalyst in contact with a gaseous or liquid solution of reactants*. Such surface, or heterogeneous, catalysis is thought to occur by chemical adsorption of the reactants onto the surface of the catalyst. *Adsorption* is the attraction of molecules to a surface. In *physical adsorption*, the attraction is provided by weak intermolecular forces. **Chemisorption**, by contrast, is *the binding of a species to a surface by chemical bonding forces*. It may happen that bonds in the species are broken during chemisorption, and this may provide the basis of catalytic action in certain cases. ▶

An example of heterogeneous catalysis involving chemisorption is provided by *catalytic hydrogenation*. This is the addition of H<sub>2</sub> to a compound, such as one with a carbon–carbon double bond, using a catalyst of platinum or nickel metal. Vegetable oils, which contain carbon–carbon double bonds, are changed to solid

Figure 13.17 ▲

#### Comparison of activation energies in the uncatalyzed and catalyzed decompositions of ozone

The uncatalyzed reaction is  $\text{O}_3 + \text{O} \longrightarrow \text{O}_2 + \text{O}_2$ . Catalysis by Cl atoms provides an alternative pathway with lower activation energy, and therefore a faster reaction.

Ozone depletion in the stratosphere was discussed in an essay at the end of Chapter 10.

Understanding the chemical processes occurring at surfaces is being advanced by new techniques, including X-ray photoelectron spectroscopy and scanning tunneling microscopy.

Charles D. Winter

Charles D. Winter

**a** The left beaker contains a 30% solution of  $\text{H}_2\text{O}_2(\text{aq})$ ; the right beaker contains a saturated solution of  $\text{KI}(\text{aq})$ .

**b** When the two solutions are mixed, the catalyzed decomposition reaction of hydrogen peroxide rapidly occurs forming water and oxygen gas. The  $\text{I}^-(\text{aq})$  is the homogeneous catalyst for this reaction. The brown color of the solution is due to the formation of iodine ( $\text{I}_2$ ) in the reaction mixture from reactions of  $\text{I}^-(\text{aq})$  with hydrogen peroxide that are not part of the mechanism described in the text.

Figure 13.18 ▲

### Catalyzed decomposition reaction of $\text{H}_2\text{O}_2$

fats (shortening) when the bonds are catalytically hydrogenated. In the case of ethylene,  $\text{C}_2\text{H}_4$ , the equation is

A mechanism for this reaction is represented by the four steps shown in Figure 13.19. In (a), ethylene and hydrogen molecules diffuse to the catalyst surface, where, as shown in (b), they undergo chemisorption. The pi electrons of ethylene form bonds to the metal, and hydrogen molecules break into H atoms that bond to the metal. In (c), two H atoms migrate to an ethylene molecule bonded to the catalyst, where they react to form ethane. Then, in (d), because ethane does not bond to the metal, it diffuses away. Note that the catalyst surface that was used in (b) is regenerated in (d).

At the beginning of this section, we described the catalytic oxidation of  $\text{SO}_2$  to  $\text{SO}_3$ , the anhydride of sulfuric acid. In an early process, the homogeneous catalyst  $\text{NO}$  was used. Today, in the *contact process*, a heterogeneous catalyst,  $\text{Pt}$  or  $\text{V}_2\text{O}_5$ , is used. Surface catalysts are used in the catalytic converters of automobiles to convert substances that would be atmospheric pollutants, such as  $\text{CO}$  and  $\text{NO}$ , into harmless substances, such as  $\text{CO}_2$  and  $\text{N}_2$  (Figure 13.20).

### Enzyme Catalysis

Almost all enzymes, the catalysts of biological organisms, are protein molecules with molecular weights ranging to over a million amu. An enzyme has enormous catalytic activity, converting a thousand or so reactant molecules to products in a second. Enzymes are also highly specific, each enzyme acting only on a specific substance, or a specific type of substance, catalyzing it to undergo a particular reaction. For example, the enzyme sucrase, which is present in the digestive fluid of the small intestine, catalyzes the reaction of sucrose (table sugar) with water to form the simpler sugars glucose and fructose. *The substance whose reaction the enzyme catalyzes is called the substrate.* Thus, the enzyme sucrase acts on the substrate sucrose.

Figure 13.21 shows schematically how an enzyme acts. The enzyme molecule is a protein chain that tends to fold into a roughly spherical form with an *active site* at which the substrate molecule binds and the catalysis takes place. The substrate molecule, S, fits into the active site on the enzyme molecule, E, somewhat in the way a key fits into a lock, forming an enzyme–substrate complex, ES. (The lock-and-key model is only a rough approximation, because the active site on an enzyme deforms somewhat to fit the substrate molecule.) In effect, the active site “recognizes” the substrate and gives the enzyme its specificity. On binding to the enzyme, the substrate may have bonds weakened or new bonds formed that help yield the products, P.

The formation of the enzyme–substrate complex provides a new pathway to products with a lower activation energy. Figure 13.22 compares the potential-energy curves of the uncatalyzed and catalyzed reactions. Note the lower activation energy of the catalyzed reaction.

Figure 13.22 ▲

**Potential-energy curves for the reaction of substrate, S, to products, P**

Figure 13.21 ▼

**Enzyme action (lock-and-key model)** The enzyme has an active site to which the substrate binds to form an enzyme–substrate complex. The active site of the enzyme acts like a lock into which the substrate (key) fits. While bound to the enzyme, the substrate may have bonds weakened or new bonds formed to yield the products, which leave the enzyme.

A CHEMIST Looks at . . .

# Seeing Molecules React

Exactly what happens when molecules react? Transition-state theory and, more recently, calculations from quantum-mechanical theory have given us insight into how molecules behave in elementary reactions. But can we actually observe *through experiment* how molecules react? Until fairly recently, this seemed an impossible dream. Molecules are so small, the distances that atoms in molecules move to break bonds and form new ones are so minuscule, and the time that it takes a reaction to occur is so short that to be able to observe molecules while they react seemed well beyond human ability.

Within the last couple of decades, however, chemistry has progressed enormously in its quest to deal with substances at the molecular level. In 1987, Ahmed H. Zewail, professor of chemistry at California Institute of Technology, managed to devise an experimental technique that can follow molecules while they are reacting. In effect, Zewail developed “the world’s smallest camera.” In the process, he founded an area of research that has come to be called “femtochemistry,” because reactions between molecules happen on the scale of femtoseconds. A femtosecond (fs) is  $10^{-15}$  s, which is a million times smaller than a billionth of a second!

### Summary of Facts and Concepts

The *reaction rate* is defined as the increase in moles of product per liter per second (or as the decrease in moles of reactant per liter per second). Rates of reaction are determined by following the change of concentration of a reactant or product, either by chemical analysis or by observing a physical property. It is found that reaction rates are proportional to concentrations of reactants raised to various powers (usually 1 or 2, but they can be fractional or negative). The *rate law* mathematically expresses the relationship between rates and concentrations for a chemical reaction. Although the rate law tells you

how the rate of a reaction depends on concentrations at a given moment, it is possible to transform a rate law to show how concentrations change with time, producing the *integrated rate law*. The *half-life* of a reaction is the time it takes for the reaction concentration to decrease to one-half of its original concentration.

Reaction rates can often double or triple with a  $10^\circ\text{C}$  rise in temperature. The effect of temperature on the rate can be explained by *collision theory*. According to this theory, two molecules react after colliding only when the energy of collision is greater than the *activation energy* and

## A CHEMIST Looks at . . . Seeing Molecules React (continued)

The experiment involves using a laser, first to send a *pump pulse* to excite a reactant molecule to a higher energy state. (See the essay on lasers at the end of Section 7.3.) Then, a weaker laser pulse or *probe pulse* of properly chosen wavelength is used to detect the molecule as it transforms to products. By varying the time between the pump pulse and the probe pulse, the experimenter can follow a molecule throughout the course of its reaction. The change of wavelength of the probe pulse tells the experimenter something about the change in character of the molecule as it reacts.

As an example of a reaction, Zewail looked at the decomposition of cyclobutane to ethylene:

Figure 13.23 shows two possible potential-energy diagrams for this reaction. The left diagram shows the cyclobutane molecule passing through a transition state (at the peak of the potential curve) in which two carbon-carbon bonds have simultaneously stretched. When the transition state goes over to products, these stretched bonds break. The right diagram shows the cyclobutane molecule going first to an intermediate molecule (between the two peaks). In this intermediate molecule, one carbon-carbon bond is broken. When the intermediate molecule goes over to products, another bond breaks, giving two ethylene molecules. Zewail and his coworkers were able to show that cyclobutane decomposed to ethylene by first going to an intermediate molecule (that is, the reaction actually goes by the potential curve on the right in Figure 13.23). The total time of the reaction was 700 fs! In

**Figure 13.24** ▲

**Ahmed H. Zewail** The chemist is shown here with his laser apparatus.

1999, Zewail (Figure 13.24) won the Nobel Prize in chemistry for his pioneering work in femtochemistry.

The techniques of femtochemistry have fundamentally altered our knowledge of chemical reactions, even in biological systems. For example, the details of the basic process of vision (which we looked at in the essay on human vision at the end of Chapter 10), in which a photon of light transforms a retinal molecule, has now been shown to occur in 200 fs, one of the fastest reactions studied.

■ See Problems 13.129 and 13.130.

when the molecules are properly oriented. It is the rapid increase in the fraction of collisions having energy greater than the activation energy that explains the large temperature dependence of reaction rates. *Transition-state theory* explains reaction rates in terms of the formation of an *activated complex* of the colliding molecules. The *Arrhenius equation* is a mathematical relationship showing the dependence of a rate constant on temperature.

A chemical equation describes the overall result of a chemical reaction that may take place in one or more steps. The steps are called *elementary reactions*, and the set of elementary reactions that describes what is happening at the molecular level in an overall reaction is called the *reaction mechanism*. In some cases, the overall reaction involves a *reaction intermediate*—a species produced in one step but used up in a subsequent one. The rate of the overall reaction depends on the rate of the slowest step (the *rate-deter-*

*mining step*). This rate is proportional to the product of the concentrations of the reactant molecules in that step. If this step involves a reaction intermediate, its concentration can be eliminated by using the relationship of the concentrations in the preceding fast, *equilibrium* step.

A *catalyst* is a substance that speeds up a chemical reaction without being consumed by it. The catalyst is used up in one step of the reaction mechanism but regenerated in a later step. Catalytic activity operates by providing a reaction mechanism that has lower activation energy. Catalysis is classified as *homogeneous catalysis* if the substances react within one phase and as *heterogeneous catalysis* if the substances in a gas or liquid phase react at the surface of a solid catalyst. Many industrial reactions involve heterogeneous catalysis. Enzymes are biological catalysts (usually proteins). *Enzyme catalysis* is highly specific, so each enzyme acts on a particular kind of *substrate*.

$$\ln \frac{[A]_t}{[A]_0} = -kt \quad (\text{first-order})$$

$$t_{1/2} = \frac{0.693}{k} \quad (\text{first-order})$$

$$\frac{1}{[A]_t} = kt + \frac{1}{[A]_0} \quad (\text{second-order})$$

$$t_{1/2} = \frac{1}{k[A]_0} \quad (\text{second-order})$$

$$[A]_t = -kt + [A]_0 \quad (\text{zero-order})$$

$$t_{1/2} = \frac{[A]_0}{2k} \quad (\text{zero-order})$$

$$\ln \frac{k_2}{k_1} = \frac{E_a}{R} \left( \frac{1}{T_1} - \frac{1}{T_2} \right)$$

**Questions and Problems****Self-Assessment and Review Questions**

**Key:** These questions test your understanding of the ideas you worked with in the chapter. These problems vary in difficulty and often can be used for the basis of discussion.

**13.1** List the four variables or factors that can affect the rate of reaction.

**13.2** Define the rate of reaction of HBr in the following reaction. How is this related to the rate of formation of Br<sub>2</sub>?

**13.3** Give at least two physical properties that might be used to determine the rate of a reaction.

**13.4** A rate of reaction depends on four variables (Question 13.1). Explain by means of an example how the rate law deals with each of these variables.

**13.5** The exponents in a rate law have no relationship to the coefficients in the overall balanced equation for the reaction. Give an example of a balanced equation and the rate law for a reaction that clearly demonstrates this.

**13.6** The reaction

is found to be first order with respect to each of the reactants. Write the rate law. What is the overall order?

**13.7** The rate of a reaction is quadrupled when the concentration of one reactant is doubled. What is the order of the reaction with respect to this reactant?

**13.8** A rate law is one-half order with respect to a reactant. What is the effect on the rate when the concentration of this reactant is doubled?

**13.9** The reaction  $\text{A}(g) \longrightarrow \text{B}(g) + \text{C}(g)$  is known to be first order in A(g). It takes 28 s for the concentration of A(g) to decrease by one-half of its initial value. How long does it take for the concentration of A(g) to decrease to one-fourth of its initial value? to one-eighth of its initial value?

**13.10** Compare the half-life equations for a first-order and a second-order reaction. For which reaction order is the value of the half-life independent of the reactant concentration?

**13.11** What two factors determine whether a collision between two reactant molecules will result in reaction?

**13.12** Sketch a potential-energy diagram for the exothermic, elementary reaction

and on it denote the activation energies for the forward and reverse reactions. Also indicate the reactants, products, and activated complex.

**13.13** Draw a structural formula for the activated complex in the following reaction:

Refer to Figure 13.16, Step 2, for details of this reaction. Use dashed lines for bonds about to form or break. Use a single line for all other bonds.

**13.14** Rate constants for reactions often follow the Arrhenius equation. Write this equation and then identify each term in it with the corresponding factor or factors from collision theory. Give a physical interpretation of each of those factors.

**13.15** By means of an example, explain what is meant by the term *reaction intermediate*.

**13.16** Why is it generally impossible to predict the rate law for a reaction on the basis of the chemical equation only?

**13.17** The rate law for the reaction

is first order in nitryl chloride,  $\text{NO}_2\text{Cl}$ .

$$\text{Rate} = k[\text{NO}_2\text{Cl}]$$

Explain why the mechanism for this reaction cannot be the single elementary reaction

**13.18** There is often one step in a reaction mechanism that is rate-determining. What characteristic of such a step makes it rate-determining? Explain.

**13.19** The dissociation of  $\text{N}_2\text{O}_4$  into  $\text{NO}_2$ ,

is believed to occur in one step. Obtain the concentration of  $\text{N}_2\text{O}_4$  in terms of the concentration of  $\text{NO}_2$  and the rate constants for the forward and reverse reactions, when the reactions have come to equilibrium.

**13.20** How does a catalyst speed up a reaction? How can a catalyst be involved in a reaction without being consumed by it?

**13.21** Compare physical adsorption and chemisorption (chemical adsorption).

**13.22** Describe the steps in the catalytic hydrogenation of ethylene.

**13.23** You are running the reaction  $2\text{A} + \text{B} \longrightarrow \text{C} + 3\text{D}$ . Your lab partner has conducted the first two experiments to determine the rate law for the reaction by the method of initial rates.

Experiment Number	Concentration of A (M)	Concentration of B (M)
1	0.0250	0.0330
2	0.0500	0.0330
3		

Presuming that you can measure the initial rate of each experiment, which of the following concentrations for Experiment 3 would help you determine the rate law easily?

**a**  $[\text{A}] = 0.0330 \text{ M}$ ,  $[\text{B}] = 0.0330 \text{ M}$

**b**  $[\text{A}] = 0.0125 \text{ M}$ ,  $[\text{B}] = 0.0500 \text{ M}$

**c**  $[\text{A}] = 0.0250 \text{ M}$ ,  $[\text{B}] = 0.0400 \text{ M}$

**d**  $[\text{A}] = 0.0250 \text{ M}$ ,  $[\text{B}] = 0.0330 \text{ M}$

**e**  $[\text{A}] = 0.0500 \text{ M}$ ,  $[\text{B}] = 0.0330 \text{ M}$

**13.24** At a constant temperature, which of the following would be expected to affect the rate of a given chemical reaction,  $\text{A} + \text{B} \longrightarrow \text{C} + \text{D}$ ?

I. The reaction temperature

II. The concentration of the products

III. A catalyst

**a** I only

**b** II only

**c** III only

**d** I and II only

**e** I and III only

**13.25** Consider the reaction  $\text{E} + \text{F} \longrightarrow \text{G} + \text{H}$ , which has the following reaction coordinate diagram.

Which one of the following statements is true?

**a** The activation energy is greatest for the forward reaction.

**b** The reactants are at a lower energy than the products.

**c** The reaction is endothermic.

**d** The rate of the forward reaction would be slowed by an increase in temperature.

**e** If the rate law for the reaction is  $\text{Rate} = k[\text{E}]^2[\text{F}]$ , then doubling the concentration of E will cause the rate to increase by a factor of 4 (that is, the reaction will proceed four times faster).

**13.26** The hypothetical reaction

has the rate law  $\text{Rate} = k[\text{A}]^2[\text{B}]$ . Which of the following changes would have the *least* effect on increasing the rate of this reaction?

**a** Doubling  $[\text{A}]_0$  while keeping  $[\text{B}]_0$  and  $[\text{C}]_0$  constant.

**b** Doubling  $[\text{B}]_0$  while keeping  $[\text{A}]_0$  and  $[\text{C}]_0$  constant.

**c** Doubling  $[\text{C}]_0$  while keeping  $[\text{A}]_0$  and  $[\text{B}]_0$  constant.

**d** Increasing the rate constant by running the reaction at a higher temperature.

**e** Adding a catalyst to the reaction mixture.

## Concept Explorations

**Key:** Concept explorations are comprehensive problems that provide a framework that will enable you to explore and learn many of the critical concepts and ideas in each chapter. If you master the concepts associated with these explorations, you will have a better understanding of many important chemistry ideas and will be more successful in solving all types of chemistry problems. These problems are well suited for group work and for use as in-class activities.

### 13.27 Kinetics I

Consider the hypothetical reaction  $\text{A}(g) + 2\text{B}(g) \rightleftharpoons \text{C}(g)$ . The four containers below represent this reaction being run with different initial amounts of A and B. Assume that the volume of each container is 1.0 L. The reaction is second order with respect to A and first order with respect to B.

- Based on the information presented in the problem, write the rate law for the reaction.
- Which of the containers, W, X, Y, or Z, would have the greatest reaction rate? Justify your answer.
- Which of the containers would have the lowest reaction rate? Explain.
- If the volume of the container X were increased to 2.0 L, how would the rate of the reaction in this larger container compare to the rate of reaction run in the 1.0-L container X? (Assume that the number of A and B atoms is the same in each case.)
- If the temperature in container W were increased, what impact would this probably have on the rate of reaction? Why?
- If you want to double the rate of reaction in container X, what are some things that you could do to the concentration(s) of A and B?
- In which container would you observe the slowest rate of formation of C?
- Assuming that A and B are not in great excess, which would have the greater impact on the rate of reaction in container W: removing a unit of B or removing a unit of A? Explain.
- Describe how the rate of consumption of A compares to the rate of consumption of B. If you cannot answer this question, what additional information do you need to provide an answer?
- If the product C were removed from the container as it formed, what effect would this have on the rate of the reaction?

### 13.28 Kinetics II

You and a friend are working together in order to obtain as much kinetic information as possible about the reaction  $A(g) \longrightarrow B(g) + C(g)$ . One thing you know before performing the experiments is that the reaction

is zero order, first order, or second order with respect to A. Your friend goes off, runs the experiment, and brings back the following graph.

- After studying the curve of the graph, she declares that the reaction is second order, with a corresponding rate law of  $\text{Rate} = k[A]^2$ . Judging solely on the basis of the information presented in this plot, is she correct in her statement that the reaction must be second order?

Here are some data collected from her experiment:

Time (s)	[A]
0.0	1.0
1.0	0.14
3.0	$2.5 \times 10^{-3}$
5.0	$4.5 \times 10^{-5}$
7.0	$8.3 \times 10^{-7}$

- The half-life of the reaction is 0.35 s. Do these data support the reaction being second order, or is it something else? Try to reach a conclusive answer without graphing the data.
- What is the rate constant for the reaction?
- The mechanism for this reaction is found to be a two-step process, with intermediates X and Y. The first step of the reaction is the rate-determining step. Write a possible mechanism for the reaction.
- You perform additional experiments and find that the rate constant doubles in value when you increase the temperature by  $10^\circ\text{C}$ . Your lab partner doesn't understand why the rate constant changes in this manner. What could you say to your partner to help her understand? Feel free to use figures and pictures as part of your explanation.

## Conceptual Problems

**Key:** These problems are designed to check your understanding of the concepts associated with some of the main topics presented in each chapter. A strong conceptual understanding of chemistry is the foundation for both applying chemical knowledge and solving chemical problems. These problems vary in level of difficulty and often can be used as a basis for group discussion.

**13.29** Consider the reaction  $3A \longrightarrow 2B + C$ .

- One rate expression for the reaction is

$$\text{Rate of formation of C} = +\frac{\Delta[C]}{\Delta t}$$

Write two other rate expressions for this reaction in this form.

- Using your two rate expressions, if you calculated the average rate of the reaction over the same time interval, would the rates be equal?
- If your answer to part b was no, write two rate expressions that would give an equal rate when calculated over the same time interval.

**13.30** Given the reaction  $2A + B \longrightarrow C + 3D$ , can you write the rate law for this reaction? If so, write the rate law; if not, why?

**13.31** The reaction  $2A(g) \longrightarrow A_2(g)$  is being run in each of the following containers. The reaction is found to be second-order with respect to A.

485c

## Rates of Reaction

- Write the rate law for the reaction.
- Which reaction container will have a greater reaction rate?
- In which container will the reaction have a shorter half-life?
- What are the relative rates of the reactions in each container?
- After a set amount of time has elapsed, which container will contain fewer A atoms?

13.32 When viewed from a molecular perspective, a particular reaction is written as

- If the reaction is first-order with a half-life of 10 seconds, complete the following pictures after 10 and 20 seconds have elapsed.

- How would the pictures from part a change if the reaction were second-order with the same half-life?
- For the first-order case, what are the relative reaction rates at the start of the reaction and after 10 seconds have elapsed?
- For the second-order case, what are the relative reaction rates at the start of the reaction and after 10 seconds have elapsed?

13.33 You perform some experiments for the reaction  $A \longrightarrow B + C$  and determine the rate law has the form

$$\text{Rate} = k[A]^x$$

Calculate the value of exponent  $x$  for each of the following.

- $[A]$  is tripled and you observe no rate change.
- $[A]$  is doubled and the rate doubles.
- $[A]$  is tripled and the rate goes up by a factor of 27.

13.34 A friend of yours runs a reaction and generates the following plot. She explains that in following the

reaction, she measured the concentration of a compound that she calls "E."

- Your friend tells you that E is either a reactant or a product. Which is it and why?
- Is the average rate faster between points A and B or B and C? Why?

13.35 Given the hypothetical plot shown here for the concentration of compound Y versus time, answer the following questions.

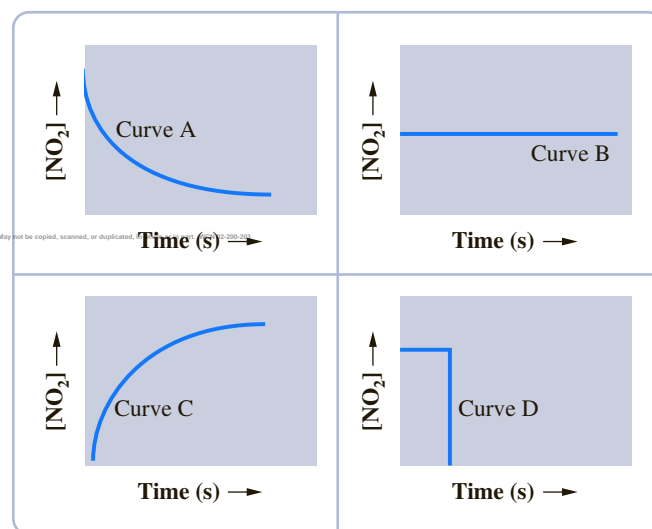

- In which region of the curve does the rate have a constant value (A, B, or C)?
- In which region of the curve is the rate the fastest (A, B, or C)?

13.36 You carry out the following reaction by introducing  $N_2O_4$  into an evacuated flask and observing the concentration change of the product over time.

Which one of the curves shown here reflects the data collected for this reaction?

13.37 You are running the reaction  $2A + B \longrightarrow C + 3D$ . Your lab partner has conducted the first two experiments to determine the rate law for the reaction. He has recorded the initial rates for these experiments in another data table.

Come up with some reactant concentrations for Experiment 3 that will allow you to determine the rate law by measuring the initial rate.

Experiment Number	Concentration of A (M)	Concentration of B (M)
1	1.0	1.0
2	2.0	1.0
3		

**13.38** The chemical reaction  $A \longrightarrow B + C$  has a rate constant that obeys the Arrhenius equation. Predict what happens to both the rate constant  $k$  and the rate of the reaction if the following were to occur.

- a a decrease in temperature
- b an increase in the activation energy of the forward and reverse reactions
- c an increase in both activation energy and temperature

## Practice Problems

**Key:** These problems are for practice in applying problem-solving skills. They are divided by topic, and some are keyed to exercises (see the ends of the exercises). The problems are arranged in matching pairs; the odd-numbered problem of each pair is listed first, and its answer is given in the back of the book.

### Reaction Rates

**13.39** Relate the rate of decomposition of  $\text{NH}_4\text{NO}_2$  to the rate of formation of  $\text{N}_2$  for the following reaction:

**13.40** For the reaction of hydrogen with iodine

relate the rate of disappearance of hydrogen gas to the rate of formation of hydrogen iodide.

**13.41** To obtain the rate of the reaction

you might follow the  $\text{Br}^-$  concentration or the  $\text{BrO}_3^-$  concentration. How are the rates in terms of these species related?

**13.42** To obtain the rate of the reaction

you might follow the  $\text{H}^+$  concentration or the  $\text{I}_3^-$  concentration. How are the rates in terms of these species related?

**13.43** Ammonium nitrite,  $\text{NH}_4\text{NO}_2$ , decomposes in solution, as shown here.

The concentration of  $\text{NH}_4^+$  ion at the beginning of an experiment was 0.500 M. After 3.00 hours, it was 0.432 M. What is the average rate of decomposition of  $\text{NH}_4\text{NO}_2$  in this time interval?

**13.44** Iron(III) chloride is reduced by tin(II) chloride.

The concentration of  $\text{Fe}^{3+}$  ion at the beginning of an experiment was 0.03586 M. After 4.00 min, it was 0.02715 M. What is the average rate of reaction of  $\text{FeCl}_3$  in this time interval?

**13.45** Azomethane,  $\text{CH}_3\text{NNCH}_3$ , decomposes according to the following equation:

The initial concentration of azomethane was  $1.50 \times 10^{-2}$  mol/L. After 7.00 min, this concentration decreased to  $1.01 \times 10^{-2}$  mol/L. Obtain the average rate of reaction during this time interval. Express the answer in units of mol/(L · s).

**13.46** Nitrogen dioxide,  $\text{NO}_2$ , decomposes upon heating to form nitric oxide and oxygen according to the following equation:

At the beginning of an experiment, the concentration of nitrogen dioxide in a reaction vessel was 0.1103 mol/L. After 65.0 s, the concentration decreased to 0.1076 mol/L. What is the average rate of decomposition of  $\text{NO}_2$  during this time interval, in mol/(L · s)?

### Rate Laws

**13.47** Hydrogen sulfide is oxidized by chlorine in aqueous solution.

The experimental rate law is

$$\text{Rate} = k[\text{H}_2\text{S}][\text{Cl}_2]$$

What is the reaction order with respect to  $\text{H}_2\text{S}$  and with respect to  $\text{Cl}_2$ ? What is the overall order?

**13.48** For the reaction of nitrogen monoxide,  $\text{NO}$ , with chlorine,  $\text{Cl}_2$ ,

the observed rate law is

$$\text{Rate} = k[\text{NO}]^2[\text{Cl}_2]$$

What is the reaction order with respect to nitrogen monoxide and with respect to  $\text{Cl}_2$ ? What is the overall order?

**13.49** Oxalic acid,  $\text{H}_2\text{C}_2\text{O}_4$ , is oxidized by permanganate ion to  $\text{CO}_2$  and  $\text{H}_2\text{O}$ .

The rate law is

$$\text{Rate} = k[\text{MnO}_4^-][\text{H}_2\text{C}_2\text{O}_4]$$

What is the order with respect to each reactant? What is the overall order?

**13.50** Iron(II) ion is oxidized by hydrogen peroxide in acidic solution.

The rate law is

$$\text{Rate} = k[\text{H}_2\text{O}_2][\text{Fe}^{2+}]$$

What is the order with respect to each reactant? What is the overall order?

**13.51** In experiments on the decomposition of azomethane,

the following data were obtained:

	<i>Initial Concentration of Azomethane</i>	<i>Initial Rate</i>
Exp. 1	$1.13 \times 10^{-2} \text{ M}$	$2.8 \times 10^{-6} \text{ M/s}$
Exp. 2	$2.26 \times 10^{-2} \text{ M}$	$5.6 \times 10^{-6} \text{ M/s}$

What is the rate law? What is the value of the rate constant?

**13.52** Ethylene oxide,  $\text{C}_2\text{H}_4\text{O}$ , decomposes when heated to give methane and carbon monoxide.

The following kinetic data were observed for the reaction at 688 K:

	<i>Initial Concentration of Ethylene Oxide</i>	<i>Initial Rate</i>
Exp. 1	$0.00272 \text{ M}$	$5.57 \times 10^{-7} \text{ M/s}$
Exp. 2	$0.00544 \text{ M}$	$1.11 \times 10^{-6} \text{ M/s}$

Find the rate law and the value of the rate constant for this reaction.

**13.53** Nitrogen monoxide, NO, reacts with hydrogen to give nitrous oxide,  $\text{N}_2\text{O}$ , and water.

In a series of experiments, the following initial rates of disappearance of NO were obtained:

	<i>Initial Concentration</i>		<i>Initial Rate of Reaction of NO</i>
	<i>NO</i>	<i>H<sub>2</sub></i>	
Exp. 1	$6.7 \times 10^{-3} \text{ M}$	$2.2 \times 10^{-3} \text{ M}$	$2.8 \times 10^{-5} \text{ M/s}$
Exp. 2	$1.3 \times 10^{-2} \text{ M}$	$2.2 \times 10^{-3} \text{ M}$	$1.1 \times 10^{-4} \text{ M/s}$
Exp. 3	$6.7 \times 10^{-3} \text{ M}$	$4.4 \times 10^{-3} \text{ M}$	$5.7 \times 10^{-5} \text{ M/s}$

Find the rate law and the value of the rate constant for the reaction of NO.

**13.54** In a kinetic study of the reaction

the following data were obtained for the initial rates of disappearance of NO:

	<i>Initial Concentrations</i>		<i>Initial Rate of Reaction of NO</i>
	<i>NO</i>	<i>O<sub>2</sub></i>	
Exp. 1	$0.0125 \text{ M}$	$0.0253 \text{ M}$	$0.0281 \text{ M/s}$
Exp. 2	$0.0250 \text{ M}$	$0.0253 \text{ M}$	$0.112 \text{ M/s}$
Exp. 3	$0.0125 \text{ M}$	$0.0506 \text{ M}$	$0.0561 \text{ M/s}$

Obtain the rate law. What is the value of the rate constant?

**13.55** Chlorine dioxide,  $\text{ClO}_2$ , is a reddish-yellow gas that is soluble in water. In basic solution it gives  $\text{ClO}_3^-$  and  $\text{ClO}_2^-$  ions.

To obtain the rate law for this reaction, the following experiments were run and, for each, the initial rate of reaction of  $\text{ClO}_2$  was determined. Obtain the rate law and the value of the rate constant.

	<i>Initial Concentrations (mol/L)</i>		<i>Initial Rate (mol(L·s))</i>
	<i>ClO<sub>2</sub></i>	<i>OH<sup>-</sup></i>	
Exp. 1	0.060	0.030	0.0248
Exp. 2	0.020	0.030	0.00276
Exp. 3	0.020	0.090	0.00828

**13.56** Iodide ion is oxidized to hypoiodite ion,  $\text{IO}^-$ , by hypochlorite ion,  $\text{ClO}^-$ , in basic solution. The equation is

The following initial-rate experiments were run and, for each, the initial rate of formation of  $\text{IO}^-$  was determined. Find the rate law and the value of the rate constant.

	<i>Initial Concentrations (mol/L)</i>			<i>Initial Rate (mol(L·s))</i>
	<i>I<sup>-</sup></i>	<i>ClO<sup>-</sup></i>	<i>OH<sup>-</sup></i>	
Exp. 1	0.010	0.020	0.010	$12.2 \times 10^{-2}$
Exp. 2	0.020	0.010	0.010	$12.2 \times 10^{-2}$
Exp. 3	0.010	0.010	0.010	$6.1 \times 10^{-2}$
Exp. 4	0.010	0.010	0.020	$3.0 \times 10^{-2}$

### Integrated Rate Laws (Change of Concentration with Time); Half-Life

**13.57** Sulfuryl chloride,  $\text{SO}_2\text{Cl}_2$ , decomposes when heated.

In an experiment, the initial concentration of  $\text{SO}_2\text{Cl}_2$  was  $8.37 \times 10^{-2} \text{ mol/L}$ . If the rate constant is  $2.2 \times 10^{-5} \text{ s}^{-1}$ , what is the concentration of  $\text{SO}_2\text{Cl}_2$  after 7.0 hr? The reaction is first order.

**13.58** Cyclopropane,  $\text{C}_3\text{H}_6$ , is converted to its isomer propylene,  $\text{CH}_2=\text{CHCH}_3$ , when heated. The rate law is first order in cyclopropane, and the rate constant is  $6.0 \times 10^{-4} \text{ s}^{-1}$  at  $500^\circ\text{C}$ . If the initial concentration of cyclopropane is  $0.0226 \text{ mol/L}$ , what is the concentration after 525 s?

**13.59** A reaction of the form  $aA \longrightarrow \text{Products}$  is second-order with a rate constant of  $0.725 \text{ L}/(\text{mol} \cdot \text{s})$ . If the initial concentration of A is  $0.760 \text{ mol/L}$ , what is the molar concentration of A after  $88.8 \text{ s}$ ?

**13.60** A reaction of the form  $aA \longrightarrow \text{Products}$  is second order with a rate constant of  $0.169 \text{ L}/(\text{mol} \cdot \text{s})$ . If the initial concentration of A is  $0.159 \text{ mol/L}$ , how many seconds would it take for the concentration of A to decrease to  $5.50 \times 10^{-3} \text{ mol/L}$ ?

**13.61** Ethyl chloride,  $\text{CH}_3\text{CH}_2\text{Cl}$ , used to produce tetraethyllead gasoline additive, decomposes, when heated, to give ethylene and hydrogen chloride.

The reaction is first order. In an experiment, the initial concentration of ethyl chloride was  $0.00100 \text{ M}$ . After heating at  $500^\circ\text{C}$  for  $155 \text{ s}$ , this was reduced to  $0.00067 \text{ M}$ . What was the concentration of ethyl chloride after a total of  $256 \text{ s}$ ?

**13.62** Cyclobutane,  $\text{C}_4\text{H}_8$ , consisting of molecules in which four carbon atoms form a ring, decomposes, when heated, to give ethylene.

The reaction is first order. In an experiment, the initial concentration of cyclobutane was  $0.00150 \text{ M}$ . After heating at  $450^\circ\text{C}$  for  $455 \text{ s}$ , this was reduced to  $0.00119 \text{ M}$ . What was the concentration of cyclobutane after a total of  $875 \text{ s}$ ?

**13.63** Methyl isocyanide,  $\text{CH}_3\text{NC}$ , isomerizes, when heated, to give acetonitrile (methyl cyanide),  $\text{CH}_3\text{CN}$ .

The reaction is first order. At  $230^\circ\text{C}$ , the rate constant for the isomerization is  $6.3 \times 10^{-4}/\text{s}$ . What is the half-life? How long would it take for the concentration of  $\text{CH}_3\text{NC}$  to decrease to  $50.0\%$  of its initial value? to  $12.5\%$  of its initial value?

**13.64** Dinitrogen pentoxide,  $\text{N}_2\text{O}_5$ , decomposes when heated in carbon tetrachloride solvent.

If the rate constant for the decomposition of  $\text{N}_2\text{O}_5$  is  $6.2 \times 10^{-4}/\text{min}$ , what is the half-life? (The rate law is first order in  $\text{N}_2\text{O}_5$ .) How long would it take for the concentration of  $\text{N}_2\text{O}_5$  to decrease to  $25\%$  of its initial value? to  $6.25\%$  of its initial value?

**13.65** In the presence of excess thiocyanate ion,  $\text{SCN}^-$ , the following reaction is first order in chromium(III) ion,  $\text{Cr}^{3+}$ ; the rate constant is  $2.0 \times 10^{-6}/\text{s}$ .

What is the half-life in hours? How many hours would be required for the initial concentration of  $\text{Cr}^{3+}$  to decrease to each of the following values:  $25.0\%$  left,  $12.5\%$  left,  $6.25\%$  left,  $3.125\%$  left?

**13.66** In the presence of excess thiocyanate ion,  $\text{SCN}^-$ , the following reaction is first order in iron(III) ion,  $\text{Fe}^{3+}$ ; the rate constant is  $1.27/\text{s}$ .

What is the half-life in seconds? How many seconds would be required for the initial concentration of  $\text{Fe}^{3+}$  to decrease to each of the following values:  $25.0\%$  left,  $12.5\%$  left,  $6.25\%$  left,  $3.125\%$  left? What is the relationship between these times and the half-life?

**13.67** A reaction of the form  $aA \longrightarrow \text{Products}$  is second order with a rate constant of  $0.164 \text{ L}/(\text{mol} \cdot \text{s})$ . What is the half-life, in seconds, of the reaction if the initial concentration of A is  $5.55 \times 10^{-3} \text{ mol/L}$ ?

**13.68** A reaction of the form  $aA \longrightarrow \text{Products}$  is second order with a half-life of  $485 \text{ s}$ . What is the rate constant of the reaction if the initial concentration of A is  $5.99 \times 10^{-3} \text{ mol/L}$ ?

**13.69** In the presence of excess thiocyanate ion,  $\text{SCN}^-$ , the following reaction is first order in chromium(III) ion,  $\text{Cr}^{3+}$ ; the rate constant is  $2.0 \times 10^{-6}/\text{s}$ .

If  $85.0\%$  reaction is required to obtain a noticeable color from the formation of the  $\text{Cr}(\text{SCN})^{2+}$  ion, how many hours are required?

**13.70** In the presence of excess thiocyanate ion,  $\text{SCN}^-$ , the following reaction is first order in iron(III) ion,  $\text{Fe}^{3+}$ ; the rate constant is  $1.27/\text{s}$ .

If  $90.0\%$  reaction is required to obtain a noticeable color from the formation of the  $\text{Fe}(\text{SCN})^{2+}$  ion, how many seconds are required?

**13.71** It is found that a gas undergoes a zero-order decomposition reaction in the presence of a nickel catalyst. If the rate constant for this reaction is  $8.1 \times 10^{-2} \text{ mol}/(\text{L} \cdot \text{s})$ , how long will it take for the concentration of the gas to change from an initial concentration of  $0.10 \text{ M}$  to  $1.0 \times 10^{-2} \text{ M}$ ?

**13.72** The reaction  $\text{A} \longrightarrow \text{B} + \text{C}$  is found to be zero order. If it takes  $5.2 \times 10^2$  seconds for an initial concentration of A to go from  $0.50 \text{ M}$  to  $0.25 \text{ M}$ , what is the rate constant for the reaction?

**13.73** Chlorine dioxide oxidizes iodide ion in aqueous solution to iodine; chlorine dioxide is reduced to chlorite ion.

The order of the reaction with respect to  $\text{ClO}_2$  was determined by starting with a large excess of  $\text{I}^-$ , so that its concentration was essentially constant. Then

$$\text{Rate} = k[\text{ClO}_2]^m[\text{I}^-]^n = k'[\text{ClO}_2]^m$$

where  $k' = k[I^-]^n$ . Determine the order with respect to  $\text{ClO}_2$  and the rate constant  $k'$  by plotting the following data assuming first- and then second-order kinetics. [Data from H. Fukutomi and G. Gordon, *J. Am. Chem. Soc.*, 89, 1362 (1967).]

Time (s)	$[\text{ClO}_2]$ (mol/L)
0.00	$4.77 \times 10^{-4}$
1.00	$4.31 \times 10^{-4}$
2.00	$3.91 \times 10^{-4}$
3.00	$3.53 \times 10^{-4}$
5.00	$2.89 \times 10^{-4}$
10.00	$1.76 \times 10^{-4}$
30.00	$2.4 \times 10^{-5}$
50.00	$3.2 \times 10^{-6}$

**13.74** Methyl acetate,  $\text{CH}_3\text{COOCH}_3$ , reacts in basic solution to give acetate ion,  $\text{CH}_3\text{COO}^-$ , and methanol,  $\text{CH}_3\text{OH}$ .

The overall order of the reaction was determined by starting with methyl acetate and hydroxide ion at the same concentrations, so  $[\text{CH}_3\text{COOCH}_3] = [\text{OH}^-] = x$ . Then

$$\text{Rate} = k[\text{CH}_3\text{COOCH}_3]^m[\text{OH}^-]^n = kx^{m+n}$$

Determine the overall order and the value of the rate constant by plotting the following data assuming first- and then second-order kinetics.

Time (min)	$[\text{CH}_3\text{COOCH}_3]$ (mol/L)
0.00	0.01000
3.00	0.00740
4.00	0.00683
5.00	0.00634
10.00	0.00463
20.00	0.00304
30.00	0.00224

### Rate and Temperature

**13.75** Sketch a potential-energy diagram for the reaction of nitric oxide with ozone.

The activation energy for the forward reaction is 10 kJ; the  $\Delta H^\circ$  is  $-200$  kJ. What is the activation energy for the reverse reaction? Label your diagram appropriately.

**13.76** Sketch a potential-energy diagram for the decomposition of nitrous oxide.

The activation energy for the forward reaction is 251 kJ; the  $\Delta H^\circ$  is +167 kJ. What is the activation energy for the reverse reaction? Label your diagram appropriately.

**13.77** In a series of experiments on the decomposition of dinitrogen pentoxide,  $\text{N}_2\text{O}_5$ , rate constants were determined at two different temperatures. At  $35^\circ\text{C}$ , the rate constant was  $1.4 \times 10^{-4}/\text{s}$ ; at  $45^\circ\text{C}$ , the rate constant was  $5.0 \times 10^{-4}/\text{s}$ . What is the activation energy for this reaction? What is the value of the rate constant at  $65^\circ\text{C}$ ?

**13.78** The reaction

has rate-constant values for the reaction of  $\text{NOCl}$  of  $9.3 \times 10^{-6}/\text{s}$  at  $350$  K and  $6.9 \times 10^{-4}/\text{s}$  at  $400$  K. Calculate the activation energy for the reaction. What is the rate constant at  $435$  K?

**13.79** The rate of a particular reaction increases by a factor of 6 when the temperature is increased from  $25^\circ\text{C}$  to  $35^\circ\text{C}$ . Calculate the activation energy for this reaction.

**13.80** The rate of a particular reaction quadruples when the temperature is increased from  $25^\circ\text{C}$  to  $42^\circ\text{C}$ . Calculate the activation energy for this reaction.

**13.81** The following values of the rate constant were obtained for the decomposition of nitrogen dioxide at various temperatures. Plot the natural logarithm of  $k$  versus  $1/T$  and from the graph obtain the energy of activation.

Temperature ( $^\circ\text{C}$ )	$k$ (L/mol·s)
320	0.527
330	0.776
340	1.121
350	1.607

**13.82** The following values of the rate constant were obtained for the decomposition of hydrogen iodide at various temperatures. Plot the natural logarithm of  $k$  versus  $1/T$  and from the graph obtain the energy of activation.

Temperature ( $^\circ\text{C}$ )	$k$ (L/mol·s)
440	$2.69 \times 10^{-3}$
460	$6.21 \times 10^{-3}$
480	$1.40 \times 10^{-2}$
500	$3.93 \times 10^{-2}$

### Reaction Mechanisms; Catalysis

**13.83** Nitrogen monoxide,  $\text{NO}$ , is believed to react with chlorine according to the following mechanism:

Identify any reaction intermediate. What is the overall equation?

**13.84** The decomposition of ozone is believed to occur in two steps:

Identify any reaction intermediate. What is the overall reaction?

**13.85** Identify the molecularity of each of the following elementary reactions.

**13.86** What is the molecularity of each of the following elementary reactions?

**13.87** Write a rate equation, showing the dependence of rate on reactant concentrations, for each of the following elementary reactions.

**13.88** Write a rate equation, showing the dependence of rate on reactant concentrations, for each of the following elementary reactions.

**13.89** The isomerization of cyclopropane,  $\text{C}_3\text{H}_6$ , is believed to occur by the mechanism shown in the following equations:

Here  $\text{C}_3\text{H}_6^*$  is an excited cyclopropane molecule. At low pressure, Step 1 is much slower than Step 2. Derive the rate law for this mechanism at low pressure. Explain.

**13.90** The thermal decomposition of nitryl chloride,  $\text{NO}_2\text{Cl}$ ,

is thought to occur by the mechanism shown in the following equations:

What rate law is predicted by this mechanism?

**13.91** The reaction

may occur by the following mechanism:

What rate law is predicted by this mechanism?

**13.92** Ozone decomposes to oxygen gas.

A proposed mechanism for this decomposition is

What is the rate law derived from this mechanism?

**13.93** The following is a possible mechanism for a reaction involving hydrogen peroxide in aqueous solution; only a small amount of sodium bromide was added to the reaction mixture.

What is the overall reaction? What species is acting as a catalyst? Are there any reaction intermediates?

**13.94** Consider the following mechanism for a reaction in aqueous solution and indicate the species acting as a catalyst:

Explain why you believe this species is a catalyst. What is the overall reaction? What substance might be added to the reaction mixture to give the catalytic activity?

## General Problems

**Key:** These problems provide more practice but are not divided by topic or keyed to exercises. Each section ends with essay questions, each of which is color coded to refer to the *A Chemist Looks at Frontiers* (purple) chapter essay on which it is based. Odd-numbered problems and the even-numbered problems that follow are similar; answers to all odd-numbered problems except the essay questions are given in the back of the book.

**13.95** A study of the decomposition of azomethane,

gave the following concentrations of azomethane at various times:

Time	$[\text{CH}_3\text{NNCH}_3]$
0 min	$1.50 \times 10^{-2} \text{ M}$
10 min	$1.29 \times 10^{-2} \text{ M}$
20 min	$1.10 \times 10^{-2} \text{ M}$
30 min	$0.95 \times 10^{-2} \text{ M}$

Obtain the average rate of decomposition in units of  $M/s$  for each time interval.

**13.96** Nitrogen dioxide decomposes when heated.

During an experiment, the concentration of  $\text{NO}_2$  varied with time in the following way:

Time	$[\text{NO}_2]$
0.0 min	0.1103 $M$
1.0 min	0.1076 $M$
2.0 min	0.1050 $M$
3.0 min	0.1026 $M$

Obtain the average rate of decomposition of  $\text{NO}_2$  in units of  $M/s$  for each time interval.

**13.97** You can write the rate law for the decomposition of azomethane as

$$\text{Rate} = k[\text{CH}_3\text{NNCH}_3]^n \quad \text{or} \quad k = \frac{\text{rate}}{[\text{CH}_3\text{NNCH}_3]^n}$$

when  $n$  is the order of the reaction. Note that when you divide the rates at various times by the concentrations raised to the correct power  $n$ , you should get the same number (the rate constant  $k$ ). Verify that the decomposition of

azomethane is first order by dividing each average rate in a time interval (obtained in Problem 13.95) by the average concentration in that interval. Note that each calculation gives nearly the same value. Take the average of these values to obtain the rate constant.

**13.98** Use the technique described in Problem 13.97 to verify that the decomposition of nitrogen dioxide is second order. That is, divide each average rate in a time interval (obtained in Problem 13.96) by the square of the average concentration in that interval. Note that each calculation gives nearly the same value. Take the average of these calculated values to obtain the rate constant.

**13.99** Methyl acetate reacts in acidic solution.

The rate law is first order in methyl acetate in acidic solution, and the rate constant at 25°C is  $1.26 \times 10^{-4}/\text{s}$ . How long will it take for 65% of the methyl acetate to react?

**13.100** Benzene diazonium chloride,  $\text{C}_6\text{H}_5\text{NNCl}$ , decomposes by a first-order rate law.

If the rate constant at 20°C is  $4.3 \times 10^{-5}/\text{s}$ , how long will it take for 65% of the compound to decompose?

**13.101** What is the half-life of methyl acetate hydrolysis at 25°C in the acidic solution described in Problem 13.99?

**13.102** What is the half-life of benzene diazonium chloride decomposition at 20°C? See Problem 13.100 for data.

**13.103** A compound decomposes by a first-order reaction. If the concentration of the compound is 0.0569 *M* after 40. s when the initial concentration was 0.0700 *M*, what is the concentration of the compound after 91 s?

**13.104** A compound decomposes by a first-order reaction. The concentration of compound decreases from 0.1180 *M* to 0.0950 *M* in 5.2 min. What fraction of the compound remains after 7.1 min?

**13.105** Butadiene can undergo the following reaction to form a dimer (two butadiene molecules hooked together).

The half-life for the reaction at a given temperature is  $5.92 \times 10^{-2}$  s. The reaction is second order.

**a** If the initial concentration of  $\text{C}_4\text{H}_8$  is 0.50 *M*, what is the rate constant for the reaction?

**b** If the initial concentration of  $\text{C}_4\text{H}_8$  is 0.010 *M*, what will be the concentration of  $\text{C}_4\text{H}_8$  after  $3.6 \times 10^2$  s?

**13.106** A plot of  $1/[A]$  versus time for the hypothetical reaction  $\text{A} \longrightarrow \text{B} + \text{C}$  yields a straight line.

**a** What is the order of the reaction?

**b** If it took 66 s for the concentration to drop 40 percent from its initial value of 0.50 *M*, what is the rate constant for the reaction?

**13.107** At 330°C, the rate constant for the decomposition of  $\text{NO}_2$  is 0.775 L/(mol·s). If the reaction is second order, what is the concentration of  $\text{NO}_2$  after  $2.5 \times 10^2$  seconds if the starting concentration was 0.050 *M*? What is the half-life of this reaction under these conditions?

**13.108** A second-order decomposition reaction run at 550°C has a rate constant of  $3.1 \times 10^{-2}$  L/(mol·s). If the initial concentration of the reactant is 0.10 *M*, what is the concentration of this reactant after  $1.5 \times 10^2$  s? What is the half-life of this reaction under these conditions?

**13.109** Plot the data given in Problem 13.95 to verify that the decomposition of azomethane is first order. Determine the rate constant from the slope of the straight-line plot of  $\log [\text{CH}_3\text{NNCH}_3]$  versus time.

**13.110** The decomposition of aqueous hydrogen peroxide in a given concentration of catalyst yielded the following data:

Time	0.0 min	5.0 min	10.0 min	15.0 min
$[\text{H}_2\text{O}_2]$	0.1000 <i>M</i>	0.0804 <i>M</i>	0.0648 <i>M</i>	0.0519 <i>M</i>

Verify that the reaction is first order. Determine the rate constant for the decomposition of  $\text{H}_2\text{O}_2$  (in units of /s) from the slope of the straight-line plot of  $\ln [\text{H}_2\text{O}_2]$  versus time.

**13.111** In the presence of a tungsten catalyst at high temperatures, the decomposition of ammonia to nitrogen and hydrogen is a zero-order process. If the rate constant at a particular temperature is  $3.7 \times 10^{-6}$  mol/(L·s), how long will it take for the ammonia concentration to drop from an initial concentration of  $5.0 \times 10^{-4}$  *M* to  $5.0 \times 10^{-5}$  *M*? What is the half-life of the reaction under these conditions?

**13.112** The reaction  $2\text{B} \longrightarrow \text{C} + 2\text{D}$  is found to be zero-order when run at 990°C. If it takes  $4.4 \times 10^2$  s for an initial concentration of B to go from 0.50 *M* to 0.20 *M*, what is the rate constant for the reaction? What is the half-life of the reaction under these conditions?

**13.113** The decomposition of nitrogen dioxide,

has a rate constant of 0.498 *M/s* at 319°C and a rate constant of 1.81 *M/s* at 354°C. What are the values of the activation energy and the frequency factor for this reaction? What is the rate constant at 420°C?

**13.114** A second-order reaction has a rate constant of  $8.7 \times 10^{-4}/(\text{M}\cdot\text{s})$  at 30°C. At 40°C, the rate constant is  $1.8 \times 10^{-3}/(\text{M}\cdot\text{s})$ . What are the activation energy and frequency factor for this reaction? Predict the value of the rate constant at 45°C.

**13.115** At high temperature, the reaction

is thought to occur in a single step. What should be the rate law in that case?

**13.116** Methyl chloride,  $\text{CH}_3\text{Cl}$ , reacts in basic solution to give methanol.

This reaction is believed to occur in a single step. If so, what should be the rate law?

**13.117** Nitryl bromide,  $\text{NO}_2\text{Br}$ , decomposes into nitrogen dioxide and bromine.

A proposed mechanism is

Write the rate law predicted by this mechanism.

**13.118** Tertiary butyl chloride reacts in basic solution according to the equation

The accepted mechanism for this reaction is

What should be the rate law for this reaction?

**13.119** Urea,  $(\text{NH}_2)_2\text{CO}$ , can be prepared by heating ammonium cyanate,  $\text{NH}_4\text{OCN}$ .

This reaction may occur by the following mechanism:

What is the rate law predicted by this mechanism?

**13.120** Acetone reacts with iodine in acidic aqueous solution to give monoiodoacetone.

A possible mechanism for this reaction is

Write the rate law that you derive from this mechanism.

**13.121** A study of the gas-phase oxidation of nitrogen monoxide at 25°C and 1.00 atm pressure gave the following results:

	<i>Conc. NO,</i> <i>mol/L</i>	<i>Conc. O<sub>2</sub>,</i> <i>mol/L</i>	<i>Initial Rate</i>
Exp. 1	$4.5 \times 10^{-2}$	$2.2 \times 10^{-2}$	$0.80 \times 10^{-2} \text{ mol}/(\text{L} \cdot \text{s})$
Exp. 2	$4.5 \times 10^{-2}$	$4.5 \times 10^{-2}$	$1.60 \times 10^{-2} \text{ mol}/(\text{L} \cdot \text{s})$
Exp. 3	$9.0 \times 10^{-2}$	$9.0 \times 10^{-2}$	$1.28 \times 10^{-1} \text{ mol}/(\text{L} \cdot \text{s})$
Exp. 4	$3.8 \times 10^{-1}$	$4.6 \times 10^{-3}$	?

**a** What is the experimental rate law for the reaction above?

**b** What is the initial rate of the reaction in Experiment 4?

**13.122** The reaction of water with  $\text{CH}_3\text{Cl}$  in acetone as a solvent is represented by the equation

The rate of the reaction doubles when the concentration of  $\text{CH}_3\text{Cl}$  is doubled and it quadruples when the concentration of  $\text{H}_2\text{O}$  is doubled.

**a** What is the unit for  $k$ ?

**b** Calculate  $k$  if  $\text{CH}_3\text{OH}$  is formed at a rate of 1.50 M/s when  $[\text{CH}_3\text{Cl}] = [\text{H}_2\text{O}] = 0.40 \text{ M}$ .

**13.123** The reaction of thioacetamide with water is shown by the equation below:

The rate of reaction is given by the rate law:

$$\text{Rate} = k[\text{H}_3\text{O}^+][\text{CH}_3\text{C}(\text{S})\text{NH}_2]$$

Consider one liter of solution that is 0.20 M in  $\text{CH}_3\text{C}(\text{S})\text{NH}_2$  and 0.15 M in HCl at 25°C.

**a** For each of the changes listed below, state whether the rate of reaction increases, decreases, or remains the same. Why?

i. A 4-g sample of NaOH is added to the solution.

ii. 500 mL of water is added to the solution.

**b** For each of the changes listed below, state whether the value of  $k$  will increase, decrease, or remain the same. Why?

i. A catalyst is added to the solution.

ii. The reaction is carried out at 15°C instead of 25°C.

**13.124** The reaction of methylacetate with water is shown by the equation below:

The rate of the reaction is given by the rate law:

$$\text{Rate} = k[\text{H}_3\text{O}^+][\text{CH}_3\text{COOCH}_3]$$

Consider one liter of solution that is 0.15 M in  $\text{CH}_3\text{COOCH}_3$  and 0.015 M in  $\text{H}_3\text{O}^+$  at 25°C.

**a** For each of the changes listed below, state whether the rate of reaction increases, decreases, or remains the same. Why?

i. Some concentrated sulfuric acid is added to the solution.

ii. Water is added to the solution.

**b** For each of the changes listed below, state whether the value of  $k$  will increase, decrease, or remain the same. Why?

i. Some concentrated sulfuric acid is added to the solution.

ii. The reaction is carried out at 35°C instead of 25°C.

**13.125** Draw a potential-energy diagram for an uncatalyzed exothermic reaction. On the same diagram, indicate the change that results on the addition of a catalyst. Discuss the role of a catalyst in changing the rate of reaction.

**13.126** Draw and label the potential-energy curve for the reaction

The activation energy for the reverse reaction is 23 kJ. Note  $\Delta H$  and  $E_a$  on the diagram. What is the activation energy for the forward reaction? For which reaction (forward or reverse) will the reaction rate be most sensitive to a temperature increase? Explain.

**13.127** What is meant by the term *rate of a chemical reaction*? Why does the rate of a reaction normally change with time? When does the rate of a chemical reaction equal the rate constant?

**13.128** Briefly discuss the factors that affect the rates of chemical reactions. Which of the factors affect the magnitude of the rate constant? Which factor(s) do not affect the magnitude of the rate constant? Why?

**13.129** Describe in general terms how chemists can follow the character of a reacting molecule using lasers.

**13.130** Describe the potential-energy curve for the decomposition of cyclobutane to ethylene.

## Strategy Problems

**Key:** As noted earlier, all of the practice and general problems are matched pairs. This section is a selection of problems that are not in matched-pair format. These challenging problems require that you employ many of the concepts and strategies that were developed in the chapter. In some cases, you will have to integrate several concepts and operational skills in order to solve the problem successfully.

**13.131** The rate constant for a certain reaction is  $1.4 \times 10^{-5} \text{ M}^{-1} \text{ min}^{-1}$  at 483 K. The activation energy for the reaction is  $2.11 \times 10^3 \text{ J/mol}$ . What is the rate constant for the reaction at 611 K?

**13.132** The decomposition of hydrogen peroxide is a first-order reaction:

The half-life of the reaction is 17.0 minutes.

- What is the rate constant of the reaction?
- If you had a bottle of  $\text{H}_2\text{O}_2$ , how long would it take for 86.0% to decompose?
- If you started the reaction with  $[\text{H}_2\text{O}_2] = 0.100 \text{ M}$ , what would be the hydrogen peroxide concentration after 15.0 minutes?

**13.133** A reaction of the form  $aA \longrightarrow \text{Products}$  is second order with a half-life of 287 s. What is the rate constant of the reaction if the initial concentration of A is  $1.87 \times 10^{-2} \text{ mol/L}$ ?

**13.134** What is the rate law for the following gas-phase elementary reaction?

**13.135** A possible mechanism for a gas-phase reaction is given below. What is the rate law predicted by this mechanism?

**13.136** Say you run the following elementary, termolecular reaction:

Using the starting concentrations  $[\text{A}] = 2.0 \text{ M}$  and  $[\text{B}] = 2.0 \text{ M}$ , you measure the rate to be  $16 \text{ M}^{-2} \cdot \text{s}^{-1}$ . What is the value of the rate constant?

**13.137** The hypothetical reaction  $\text{A} + 2\text{B} \longrightarrow \text{Products}$  has the rate law  $\text{Rate} = k[\text{A}]^2[\text{B}]^3$ . If the reaction is run two separate times, holding the concentration of A constant while doubling the concentration of B from one run to the next, how would the rate of the second run compare to the rate of the first run?

**13.138** For the decomposition of one mole of nitrosyl chloride,  $\Delta H = 38 \text{ kJ}$ .

The activation energy for this reaction is 100 kJ.

- Is this reaction exothermic or endothermic?
- What is the activation energy for the reverse reaction?
- If a catalyst were added to the reaction, how would this affect the activation energy?

**13.139** Given the following mechanism for a chemical reaction:

- Write the overall reaction.
- Identify the catalyst and the reaction intermediate.
- With the information given in this problem, can you write the rate law? Explain.

**13.140** The following data were collected for the reaction  $\text{A}(g) + \text{B}(g) \longrightarrow \text{Products}$ .

Experiment	$[\text{A}]_0 \text{ (M)}$	$[\text{B}]_0 \text{ (M)}$	Rate (M/s)
1	0.0100	0.100	$1.0 \times 10^{-3}$
2	0.0300	0.100	$3.0 \times 10^{-3}$
3	0.0300	0.300	$2.7 \times 10^{-2}$

- Determine the rate law for this reaction.
- Calculate the rate constant.
- Calculate the rate when  $[\text{A}] = 0.200 \text{ M}$  and  $[\text{B}] = 0.200 \text{ M}$ .

**13.141** A hypothetical reaction has the two-step mechanism

The potential-energy curve for the reaction is

- Write the chemical formulas of the reactants, products, and the reaction intermediate on the potential-energy curve.
- From the mechanism, what is the overall reaction?
- What is the rate-limiting step for the reaction?
- Propose a rate law based on the rate-limiting step.
- Is the reaction exothermic or endothermic?

**13.142** The rate law for reaction  $\text{O}_3(\text{g}) + \text{NO}(\text{g}) \longrightarrow \text{O}_2(\text{g}) + \text{NO}_2(\text{g})$  is first order in  $\text{O}_3$  and first order in  $\text{NO}$ . The reaction is exothermic, and the temperature dependence of the rate constant can be modeled by the Arrhenius equation. Which of the following statements regarding this reaction are true as the temperature of the reaction is increased (choose all that apply)?

- a The reaction rate would increase.
- b The activation energy would increase.
- c A greater percentage of the molecular collisions between  $\text{O}_3$  and  $\text{NO}$  in a reaction mixture would exceed the activation energy.
- d The reaction would become more exothermic.
- e The magnitude of the rate constant would increase.

**13.143** A series of kinetics experiments are conducted on the hypothetical reaction  $\text{A} + 2\text{B} \longrightarrow \text{AB}_2$ . Prior to conducting experiments, there are four proposed rate laws

$$\begin{aligned} \text{rate} &= k [\text{A}]^2[\text{B}] \\ \text{rate} &= k [\text{A}][\text{B}] \\ \text{rate} &= k [\text{A}][\text{B}]^2 \\ \text{rate} &= k [\text{A}][\text{B}]^4 \end{aligned}$$

Experimental data indicates that when the concentration of A is doubled while the concentration of B is held constant, the rate of the reaction doubles. The data also shows that when the concentration of A is held constant and the concentration of B is doubled, the rate of the reaction increases by a factor of four.

- a Which of the proposed rate laws is consistent with the experimental data?
- b Using your answer from part a, predict the change in the initial rate for a reaction in which the concentration

of A is reduced by 50% and the concentration of B is increased by 100%.

- c If you were to run the reaction with  $[\text{A}]_0 = 0.10 \text{ M}$  and  $[\text{B}]_0 = 0.10 \text{ M}$ , sketch a concentration versus time graph depicting the changes in concentration of both A and B.

**13.144** For many reactions, the reaction rate approximately doubles with every  $10^\circ\text{C}$  increase in temperature. Using this approximation, if a reaction were run at  $35^\circ\text{C}$  and then at  $75^\circ\text{C}$ , how would the reaction rates compare at these two temperatures?

**13.145** Dinitrogen pentoxide decomposes according to the reaction

At  $45^\circ\text{C}$  the rate constant is  $6.2 \times 10^{-4} \text{ s}^{-1}$ . The reaction is first order.

- a Write the rate law for the reaction.
- b Calculate the rate of the reaction when  $[\text{N}_2\text{O}_5]$  is  $0.20 \text{ M}$ .
- c Calculate the half-life of the reaction.
- d If the initial concentration of  $\text{N}_2\text{O}_5$  is  $0.50 \text{ M}$ , what is the concentration of  $[\text{N}_2\text{O}_5]$  after 1.5 hours?

**13.146** A substance is found to have a reaction with the form  $a\text{A} \longrightarrow \text{products}$ . A  $1/[\text{A}]$  versus time plot of experimental data at  $25^\circ\text{C}$  produced a straight line with a slope of  $2.8 \times 10^{-2} \text{ L}/(\text{mol} \cdot \text{sec})$ .

- a What is the rate constant for the reaction?
- b If the initial concentration of A is  $1.9 \times 10^{-4} \text{ M}$ , what is the half-life of the reaction?
- c If the initial concentration of A is  $2.1 \times 10^{-3} \text{ M}$ , what is the concentration of A after 275 seconds?

## Capstone Problems

**Key:** The problems under this heading combine skills, strategies, and concepts learned in previous chapters with those introduced in the current one.

**13.147** Dinitrogen pentoxide,  $\text{N}_2\text{O}_5$ , undergoes first-order decomposition in chloroform solvent to yield  $\text{NO}_2$  and  $\text{O}_2$ . The rate constant at  $45^\circ\text{C}$  is  $6.2 \times 10^{-4}/\text{min}$ . Calculate the volume of  $\text{O}_2$  obtained from the reaction of  $1.00 \text{ mol N}_2\text{O}_5$  at  $45^\circ\text{C}$  and  $770 \text{ mmHg}$  after  $20.0 \text{ hr}$ .

**13.148** Hydrogen peroxide undergoes a first-order decomposition to water and  $\text{O}_2$  in aqueous solution. The rate constant at  $25^\circ\text{C}$  is  $7.40 \times 10^{-4}/\text{s}$ . Calculate the volume of  $\text{O}_2$  obtained from the decomposition reaction of  $1.00 \text{ mol H}_2\text{O}_2$  at  $25^\circ\text{C}$  and  $740 \text{ mmHg}$  after  $30.0 \text{ min}$ .

**13.149** Hydrogen peroxide in aqueous solution decomposes by a first-order reaction to water and oxygen. The rate constant for this decomposition is  $7.40 \times 10^{-4}/\text{s}$ . What quantity of heat energy is initially liberated per second from  $2.00 \text{ L}$  of solution that is  $1.50 \text{ M H}_2\text{O}_2$ ? See Appendix C for data.

**13.150** Nitrogen dioxide reacts with carbon monoxide by the overall equation

At a particular temperature, the reaction is second order in  $\text{NO}_2$  and zero order in  $\text{CO}$ . The rate constant is

$0.515 \text{ L}/(\text{mol} \cdot \text{s})$ . How much heat energy evolves per second initially from  $3.50 \text{ L}$  of reaction mixture containing  $0.0275 \text{ M NO}_2$ ? See Appendix C for data. Assume the enthalpy change is constant with temperature.

**13.151** Nitrogen monoxide reacts with oxygen to give nitrogen dioxide.

The rate law is  $-\Delta[\text{NO}]/\Delta t = k[\text{NO}]^2[\text{O}_2]$ , where the rate constant is  $1.16 \times 10^{-5} \text{ L}^2/(\text{mol}^2 \cdot \text{s})$  at  $339^\circ\text{C}$ . A vessel contains  $\text{NO}$  and  $\text{O}_2$  at  $339^\circ\text{C}$ . The initial partial pressures of  $\text{NO}$  and  $\text{O}_2$  are  $155 \text{ mmHg}$  and  $345 \text{ mmHg}$ , respectively. What is the rate of decrease of partial pressure of  $\text{NO}$  (in  $\text{mmHg}$  per second)? (*Hint:* From the ideal gas law, obtain an expression for the molar concentration of a particular gas in terms of its partial pressure.)

**13.152** Nitrogen monoxide reacts with hydrogen as follows:

The rate law is  $-\Delta[\text{H}_2]/\Delta t = k[\text{NO}]^2[\text{H}_2]$ , where  $k$  is  $1.10 \times 10^{-7} \text{ L}^2/(\text{mol}^2 \cdot \text{s})$  at  $826^\circ\text{C}$ . A vessel contains  $\text{NO}$  and  $\text{H}_2$  at  $826^\circ\text{C}$ . The partial pressures of  $\text{NO}$  and  $\text{H}_2$  are  $144 \text{ mmHg}$  and  $315 \text{ mmHg}$ , respectively. What is the rate of decrease of partial pressure of  $\text{NO}$ ? See Problem 13.151.

## 14

Chemical  
Equilibrium

The reddish brown hue of the smog over this Jakarta, Indonesia skyline is due to nitrogen dioxide,  $\text{NO}_2$ , which is in equilibrium with colorless dinitrogen tetroxide,  $\text{N}_2\text{O}_4$ .

## CONTENTS AND CONCEPTS

**Describing Chemical Equilibrium**

Many chemical reactions can be made to go in either the forward or the reverse direction, depending on the conditions of the reaction. In the next few sections, we will look at this reversibility.

**14.1** Chemical Equilibrium—A Dynamic Equilibrium

**14.2** The Equilibrium Constant

**14.3** Heterogeneous Equilibria; Solvents in Homogeneous Equilibria

**Using the Equilibrium Constant**

The various possible equilibrium compositions of a reaction mixture at a given temperature are characterized by the *equilibrium constant* for the reaction. In the next sections, we look at how we can use this

equilibrium constant to answer important questions.

**14.4** Qualitatively Interpreting the Equilibrium Constant

**14.5** Predicting the Direction of Reaction

**14.6** Calculating Equilibrium Concentrations

**Changing the Reaction Conditions; Le Châtelier's Principle**

We obtain the maximum product from a reaction by properly selecting the reaction conditions. We look at the various ways to do this in the last sections of the chapter.

**14.7** Removing Products or Adding Reactants

**14.8** Changing the Pressure and Temperature

**14.9** Effect of a Catalyst

**C**hemical reactions often seem to stop before they are complete. Such reactions are *reversible*. That is, the original reactants form products, but then the products react with themselves to give back the original reactants. Actually two reactions are occurring, and the eventual result is a mixture of reactants and products, rather than simply a mixture of products.

Consider the gaseous reaction in which carbon monoxide and hydrogen react to produce methane and steam:

This reaction, which requires a catalyst to occur at a reasonable rate, is called *catalytic methanation*. It is a potentially useful reaction because it can be used to produce methane from coal or organic wastes from which carbon monoxide can be obtained (Figure 14.1). Methane, in turn, can be used as a fuel and as a starting material for the production of organic chemicals. Although, at the moment, natural gas (which is mostly methane) is plentiful, analysts predict that oil and natural gas production will peak sometime this century. Then the demand for other sources of fuels and organic chemicals, such as coal and organic wastes, will rise.

Catalytic methanation is a reversible reaction, and depending on the reaction conditions, the final reaction mixture will have varying amounts of the products methane and steam, as well as the starting substances carbon monoxide and hydrogen. It is also possible to start with methane and steam and, under the right conditions, form a mixture that is predominantly carbon monoxide and hydrogen. The process is called *steam reforming*.

The product mixture of CO and H<sub>2</sub> (synthesis gas) is used to prepare a number of industrial chemicals.

The processes of catalytic methanation and steam reforming illustrate the reversibility of chemical reactions. An important question is, What conditions favor the production of CH<sub>4</sub> and H<sub>2</sub>O from CO and H<sub>2</sub>, and what conditions favor the production of CO and H<sub>2</sub> from CH<sub>4</sub> and H<sub>2</sub>O?

As noted earlier, certain reactions (such as catalytic methanation) appear to stop before they are complete. The reaction mixture ceases to change in any of its properties and consists of both reactants and products in definite concentrations. Such a reaction mixture is said to have reached *chemical equilibrium*. In earlier chapters, we discussed other types of equilibria, including the equilibrium between a liquid and its vapor and the equilibrium between a solid and its saturated solution. In this chapter, we will see how to determine the composition of a reaction mixture at equilibrium and how to alter this composition by changing the conditions for the reaction.

**Figure 14.1** ▲

**Coal gasification plant** Gaseous fuels can be made from coal in a number of ways. One way (described in the text) is to react coal with steam to produce a mixture of CO and H<sub>2</sub>, which then reacts by catalytic methanation to yield CH<sub>4</sub>, the major component of natural gas.

## ► Describing Chemical Equilibrium

Many chemical reactions are like the catalytic methanation reaction. Such reactions can be made to go predominantly in one direction or the other, depending on the conditions. Let us look more closely at this reversibility and see how to characterize it quantitatively.

### 14.1 Chemical Equilibrium—A Dynamic Equilibrium

When substances react, they eventually form a mixture of reactants and products in *dynamic equilibrium*. ► This dynamic equilibrium consists of a forward reaction, in which substances react to give products, and a reverse reaction, in which products

The concept of dynamic equilibrium in chemical reactions was briefly mentioned in Section 13.8. Discussions on vapor pressure (Section 11.2) and solubility (Section 12.2) give detailed explanations of the role of dynamic equilibria.

react to give the original reactants. Both forward and reverse reactions occur at the same rate, or speed.

Consider the catalytic methanation reaction discussed in the chapter opening. It consists of forward and reverse reactions, as represented by the chemical equation:

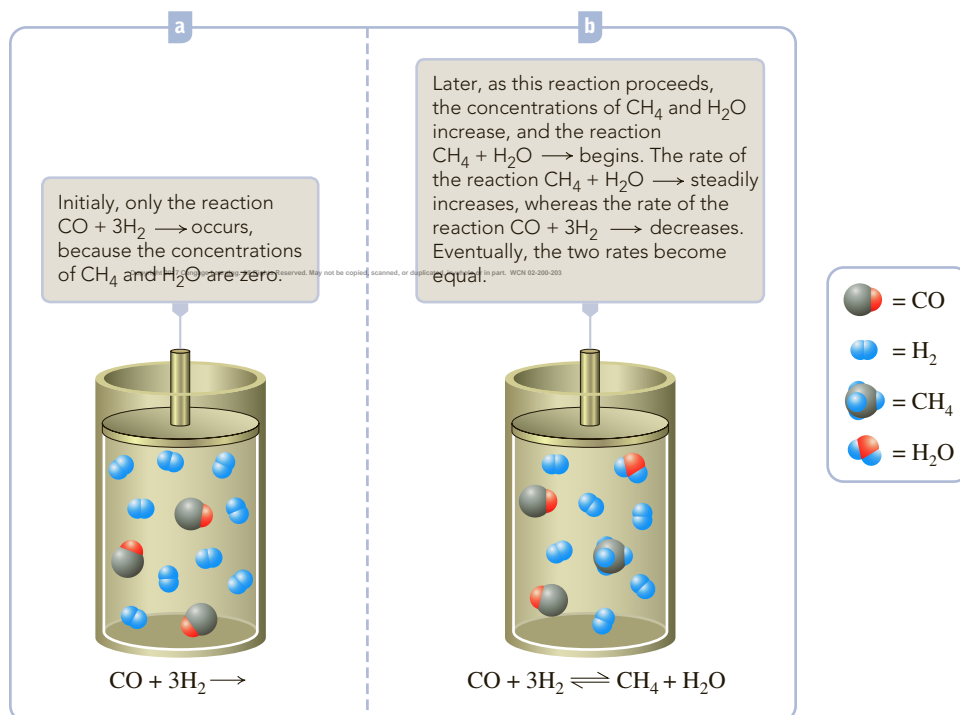

Suppose you put 1.000 mol CO and 3.000 mol H<sub>2</sub> into a 10.00-L vessel at 1200 K (927°C). The rate of the reaction of CO and H<sub>2</sub> depends on the concentrations of CO and H<sub>2</sub>. At first these concentrations are large, but as the substances react their concentrations decrease (Figure 14.2). The rate of the forward reaction, which depends on reactant concentrations, is large at first but steadily decreases. On the other hand, the concentrations of CH<sub>4</sub> and H<sub>2</sub>O, which are zero at first, increase with time. The rate of the reverse reaction starts at zero and steadily increases. The forward rate decreases and the reverse rate increases until eventually the rates become equal. When that happens, CO and H<sub>2</sub> molecules are formed as fast as they react. The concentrations of reactants and products no longer change, and the reaction mixture has reached *equilibrium*. Figure 14.3 shows how the amounts of substances in the reaction mixture become constant when equilibrium is reached.

**Chemical equilibrium** is the state reached by a reaction mixture when the rates of forward and reverse reactions have become equal. If you observe the reaction mixture, you see no net change, although the forward and reverse reactions are continuing. The continuing forward and reverse reactions make the equilibrium a *dynamic* process.

Suppose you place known amounts of reactants in a vessel and let the mixture come to equilibrium. To obtain the composition of the equilibrium mixture, you need to determine the amount of only one of the substances. The amounts of the others can be calculated from the amounts originally placed in the vessel and the equation that represents the reaction. For example, suppose you place 1.000 mol CO and 3.000 mol H<sub>2</sub> in a reaction vessel at 1200 K. After equilibrium is reached, you chill the reaction mixture quickly to condense the water vapor to liquid, which you then weigh and find to be 0.387 mol. You calculate the other substances from the stoichiometry of the reaction, as shown in the following example.

**Figure 14.2** ▶  
Change of rates as reaction proceeds

**a** The experiment begins with 1.000 mol CO and 3.000 mol H<sub>2</sub> in a 10.00-L vessel. Note that the amounts of substances become constant at equilibrium.

**b** The forward rate is large at first but steadily decreases, whereas the reverse rate starts at zero and steadily increases. Eventually both rates become equal (at equilibrium).

**Figure 14.3** ◀  
Catalytic methanation reaction approaches equilibrium

### Example 14.1 Applying Stoichiometry to an Equilibrium Mixture

#### Gaining Mastery Toolbox

##### Critical Concept 14.1

This is a problem in stoichiometry; we set it up in tabular form with the chemical equation forming the heading, a useful procedure for the equilibrium calculations in this chapter.

##### Solution Essentials:

- Table for change amounts in a reaction
- Stoichiometry

Carbon monoxide and hydrogen react according to the following equation:

When 1.000 mol CO and 3.000 mol H<sub>2</sub> are placed in a 10.00-L vessel at 927°C (1200 K) and allowed to come to equilibrium, the mixture is found to contain 0.387 mol H<sub>2</sub>O. What is the molar composition of the equilibrium mixture? That is, how many moles of each substance are present?

**Problem Strategy** The problem is essentially one of stoichiometry. It involves initial, or *starting*, amounts of reactants. These amounts *change* as the reaction comes to equilibrium. At equilibrium, you analyze the reaction mixture for the amount of one of the reactants or products. It is convenient to solve this problem by first setting up a table in which you write the starting, change, and equilibrium values of each substance under the balanced equation. This way you can easily see what you have to calculate.

<i>Amount (mol)</i>	$\text{CO}(g) + 3\text{H}_2(g) \rightleftharpoons \text{CH}_4(g) + \text{H}_2\text{O}(g)$				
Starting					
Change					
Equilibrium					

You fill in the starting amounts from the values given in the problem statement. You are not given explicit values for the changes that occur in going to equilibrium, so you let  $x$  be the molar change. That is, each product increases by  $x$  moles multiplied by the coefficients of the substances in the balanced equation. Reactants decrease by  $x$  moles multiplied by the corresponding coefficients. The decrease is indicated by a negative sign. Equilibrium values are equal to starting values plus the changes.

**Solution** Using the information given in the problem, you set up the following table:

<i>Amount (mol)</i>	$\text{CO}(g)$	+	$3\text{H}_2(g)$	$\rightleftharpoons$	$\text{CH}_4(g)$	+	$\text{H}_2\text{O}(g)$
Starting	1.000		3.000		0		0
Change	$-x$		$-3x$		$+x$		$+x$
Equilibrium	$1.000 - x$		$3.000 - 3x$		$x$		$x = 0.387$

(continued)

**Example 14.1** (continued)

The problem statement gives the equilibrium amount for H<sub>2</sub>O. This tells you that  $x = 0.387$  mol. You calculate equilibrium amounts for other substances from the expressions given in the table, using this value of  $x$ .

$$\begin{aligned}\text{Equilibrium amount CO} &= (1.000 - x) \text{ mol} \\ &= (1.000 - 0.387) \text{ mol} \\ &= 0.613 \text{ mol}\end{aligned}$$

$$\begin{aligned}\text{Equilibrium amount H}_2 &= (3.000 - 3x) \text{ mol} \\ &= (3.000 - 3 \times 0.387) \text{ mol} \\ &= 1.839 \text{ mol}\end{aligned}$$

$$\text{Equilibrium amount CH}_4 = x \text{ mol} = 0.387 \text{ mol}$$

Therefore, the amounts of substances in the equilibrium mixture are **0.613 mol CO, 1.839 mol H<sub>2</sub>, 0.387 mol CH<sub>4</sub>, and 0.387 mol H<sub>2</sub>O.**

**Answer Check** You start with 4.000 mol reactants (1.000 mol CO + 3.000 mol H<sub>2</sub>). If the reaction were to go to completion, you would obtain 2.000 mol products (1.000 mol CH<sub>4</sub> + 1.000 mol H<sub>2</sub>O). The equilibrium quantities will be intermediate. Check that this is the case.

**Exercise 14.1** Synthesis gas (a mixture of CO and H<sub>2</sub>) is increased in the concentration of hydrogen by passing it with steam over a catalyst. This is the so-called water–gas shift reaction. Some of the CO is converted to CO<sub>2</sub>, which can be removed:

Suppose you start with a gaseous mixture containing 1.00 mol CO and 1.00 mol H<sub>2</sub>O. When equilibrium is reached at 1000°C, the mixture contains 0.43 mol H<sub>2</sub>. What is the molar composition of the equilibrium mixture?

See Problems 14.29, 14.30, 14.31, 14.32, 14.33, and 14.34.

**CONCEPT CHECK 14.1**

Two substances A and B react to produce substance C. When reactant A decreases by molar amount  $x$ , product C increases by molar amount  $x$ . When reactant B decreases by molar amount  $x$ , product C increases by molar amount  $2x$ . Write the chemical equation for the reaction.

**14.2 The Equilibrium Constant**

In the preceding example, we found that when 1.000 mol CO and 3.000 mol H<sub>2</sub> react in a 10.00-L vessel by catalytic methanation at 1200 K, they give an equilibrium mixture containing 0.613 mol CO, 1.839 mol H<sub>2</sub>, 0.387 mol CH<sub>4</sub>, and 0.387 mol H<sub>2</sub>O. Let us call this Experiment 1. Now consider a similar experiment, Experiment 2, in which you start with an additional mole of carbon monoxide. That is, you place 2.000 mol CO and 3.000 mol H<sub>2</sub> in a 10.00-L vessel at 1200 K. At equilibrium, you find that the vessel contains 1.522 mol CO, 1.566 mol H<sub>2</sub>, 0.478 mol CH<sub>4</sub>, and 0.478 mol H<sub>2</sub>O. What you observe from the results of Experiments 1 and 2 is that the equilibrium composition depends on the amounts of starting substances. Nevertheless, you will see that all of the equilibrium compositions for a reaction at a given temperature are related by a quantity called the *equilibrium constant*.

## Definition of the Equilibrium Constant $K_c$

Consider the reaction

where A, B, C, and D denote reactants and products, and  $a$ ,  $b$ ,  $c$ , and  $d$  are coefficients in the balanced chemical equation. The **equilibrium-constant expression** for a reaction is *an expression obtained by multiplying the concentrations of products, dividing by the concentrations of reactants, and raising each concentration term to a power equal to the coefficient in the chemical equation*. The **equilibrium constant  $K_c$**  is the value obtained for the equilibrium-constant expression when equilibrium concentrations are substituted. ► For the previous reaction, you have

$$K_c = \frac{[C]^c [D]^d}{[A]^a [B]^b}$$

Here you denote the molar concentration of a substance by writing its formula in square brackets. The subscript  $c$  on the equilibrium constant means that it is defined in terms of molar concentrations. The **law of mass action** is *a relation that states that the values of the equilibrium-constant expression  $K_c$  are constant for a particular reaction at a given temperature, whatever equilibrium concentrations are substituted*. ►

As the following example illustrates, the equilibrium-constant expression is defined in terms of the balanced chemical equation. If the equation is rewritten with different coefficients, the equilibrium-constant expression will be changed.

In Section 14.3, you will see that you ignore concentrations of pure liquids and solids when you write the equilibrium-constant expression. The concentrations of these substances are constant and are incorporated into the value of  $K_c$ .

“Active mass” was an early term for concentration—hence the term mass action.

### Example 14.2 Writing Equilibrium-Constant Expressions

#### Gaining Mastery Toolbox

##### Critical Concept 14.2

You can write the equilibrium-constant expression given any balanced chemical equation.

##### Solution Essentials:

- Equilibrium-constant expression,  $K_c$
- Balanced equation

- a. Write the equilibrium-constant expression  $K_c$  for catalytic methanation.

- b. Write the equilibrium-constant expression  $K_c$  for the reverse of the previous reaction.

- c. Write the equilibrium-constant expression  $K_c$  for the synthesis of ammonia.

- d. Write the equilibrium-constant expression  $K_c$  when the equation for the previous reaction is written

**Problem Strategy** Write the concentrations of products in the top (numerator) of the equilibrium-constant expression, and write the concentrations of reactants in the bottom (denominator). Raise each concentration term to the power equal to the coefficient of the substance in the chemical equation.

#### Solution

- a. The expression for the equilibrium constant is

$$K_c = \frac{[\text{CH}_4][\text{H}_2\text{O}]}{[\text{CO}][\text{H}_2]^3}$$

Note that concentrations of products are on the top and concentrations of reactants are on the bottom. Also note that each concentration term is raised to a power equal to the coefficient of the substance in the chemical equation.

- b. When the equation is written in reverse order, the expression for  $K_c$  is inverted:

$$K_c = \frac{[\text{CO}][\text{H}_2]^3}{[\text{CH}_4][\text{H}_2\text{O}]}$$

(continued)

**Example 14.2** (continued)

c. The equilibrium constant for  $\text{N}_2 + 3\text{H}_2 \rightleftharpoons 2\text{NH}_3$  is

$$K_c = \frac{[\text{NH}_3]^2}{[\text{N}_2][\text{H}_2]^3}$$

d. When the coefficients in the equation in part c are multiplied by  $\frac{1}{2}$  to give

the equilibrium-constant expression becomes

$$K_c = \frac{[\text{NH}_3]}{[\text{N}_2]^{1/2}[\text{H}_2]^{3/2}}$$

which is the square root of the previous expression.

**Answer Check** Check your answers. Make sure that the products are on top and the reactants are on the bottom of each equilibrium-constant expression. Then check that each reactant and product term is raised to the correct power (equal to the stoichiometric coefficient in the chemical equation).

**Exercise 14.2** a. Write the equilibrium-constant expression  $K_c$  for the equation

b. Write the equilibrium-constant expression  $K_c$  when this reaction is written

See Problems 14.35 and 14.36.

**Figure 14.4** ▲

**Temperature effect on  $\text{NO}_2$ – $\text{N}_2\text{O}_4$  equilibrium** The temperature in the test tubes increases from left to right.  $\text{N}_2\text{O}_4$  (colorless) predominates at cooler temperatures, whereas  $\text{NO}_2$  (reddish brown) predominates at higher temperatures.

### Equilibrium: A Kinetics Argument

The law of mass action was first stated by the Norwegian chemists Cato Guldberg and Peter Waage in 1867. They were led to this law by a kinetics argument. To understand the argument, consider the decomposition of dinitrogen tetroxide,  $\text{N}_2\text{O}_4$ .

Dinitrogen tetroxide is a colorless substance that decomposes, when warmed, to give nitrogen dioxide,  $\text{NO}_2$ , a brown substance (see Figure 14.4). Suppose you start with dinitrogen tetroxide gas and heat it above room temperature. At this higher temperature,  $\text{N}_2\text{O}_4$  decomposes to  $\text{NO}_2$ , which can be noted by the increasing intensity of the brown color of the reaction mixture.

Once some  $\text{NO}_2$  is produced, it can react to re-form  $\text{N}_2\text{O}_4$ . Call the decomposition of  $\text{N}_2\text{O}_4$  the forward reaction and the formation of  $\text{N}_2\text{O}_4$  the reverse reaction. These are elementary reactions, and you can immediately write the rate equations. The rate of the forward reaction is  $k_f[\text{N}_2\text{O}_4]$ , where  $k_f$  is the rate constant for the forward reaction. The rate of the reverse reaction is  $k_r[\text{NO}_2]^2$ , where  $k_r$  is the rate constant for the reverse reaction.

At first, the reaction vessel contains mostly  $\text{N}_2\text{O}_4$ , so the concentration of  $\text{NO}_2$  is very small. Therefore, the rate of the forward reaction is relatively large, and the rate of the reverse reaction is relatively small. However, as the decomposition proceeds, the concentration of  $\text{N}_2\text{O}_4$  decreases, so the forward rate decreases. At the same time,

the concentration of  $\text{NO}_2$  increases, so the reverse rate increases. Eventually the two rates become equal. After that, on average, every time an  $\text{N}_2\text{O}_4$  molecule decomposes, two  $\text{NO}_2$  molecules recombine. Overall, the concentrations of  $\text{N}_2\text{O}_4$  and  $\text{NO}_2$  no longer change, although forward and reverse reactions are still occurring. The reaction has reached a dynamic equilibrium.

At equilibrium, you can write: Rate of forward reaction = rate of reverse reaction, or

$$k_f[\text{N}_2\text{O}_4] = k_r[\text{NO}_2]^2$$

Rearranging gives

$$\frac{k_f}{k_r} = \frac{[\text{NO}_2]^2}{[\text{N}_2\text{O}_4]}$$

The right side is the equilibrium-constant expression for the decomposition of dinitrogen tetroxide. The left side is the ratio of rate constants. Thus, the equilibrium-constant expression is constant for a given temperature, and you can identify the equilibrium constant  $K_c$  as the ratio of rate constants for the forward and reverse reactions.

$$K_c = \frac{k_f}{k_r}$$

If the overall reaction occurs by a multistep mechanism, one can show that the equilibrium constant equals a product of ratios of rate constants—one ratio for each step in the mechanism.

### Obtaining Equilibrium Constants for Reactions

At the beginning of this section, we gave data from the results of two experiments, Experiments 1 and 2, involving catalytic methanation. By substituting the molar concentrations from these two experiments into the equilibrium-constant expression for the reaction, you can show that you get the same value for both experiments, as you expect from the law of mass action. This value equals  $K_c$  for methanation at 1200 K. Thus, besides verifying the validity of the law of mass action in this case, you can see how an equilibrium constant can be obtained from concentration data. ►

**Experiment 1** The equilibrium composition is 0.613 mol CO, 1.839 mol  $\text{H}_2$ , 0.387 mol  $\text{CH}_4$ , and 0.387 mol  $\text{H}_2\text{O}$ . The volume of the reaction vessel is 10.00 L, so the equilibrium concentration of CO is

$$[\text{CO}] = \frac{0.613 \text{ mol}}{10.00 \text{ L}} = 0.0613 \text{ M}$$

Similarly, the other equilibrium concentrations are  $[\text{H}_2] = 0.1839 \text{ M}$ ,  $[\text{CH}_4] = 0.0387 \text{ M}$ , and  $[\text{H}_2\text{O}] = 0.0387 \text{ M}$ .

Substitute these values into the equilibrium expression for catalytic methanation. (The expression was obtained in Example 14.2.) Although until now we have consistently carried units along with numbers in calculations, it is the usual practice to write equilibrium constants without units. We will follow that practice here. ► Substitution of concentrations into the equilibrium-constant expression gives

$$K_c = \frac{[\text{CH}_4][\text{H}_2\text{O}]}{[\text{CO}][\text{H}_2]^3} = \frac{(0.0387)(0.0387)}{(0.0613)(0.1839)^3} = 3.93$$

**Experiment 2** The equilibrium composition is 1.522 mol CO, 1.566 mol  $\text{H}_2$ , 0.478 mol  $\text{CH}_4$ , and 0.478 mol  $\text{H}_2\text{O}$ . Therefore, the concentrations, which are obtained by dividing by 10.00 L, are  $[\text{CO}] = 0.1522 \text{ M}$ ,  $[\text{H}_2] = 0.1566 \text{ M}$ ,  $[\text{CH}_4] = 0.0478 \text{ M}$ , and  $[\text{H}_2\text{O}] = 0.0478 \text{ M}$ . Substituting into the equilibrium-constant expression gives

$$K_c = \frac{[\text{CH}_4][\text{H}_2\text{O}]}{[\text{CO}][\text{H}_2]^3} = \frac{(0.0478)(0.0478)}{(0.1522)(0.1566)^3} = 3.91$$

It is also possible to determine equilibrium constants from thermochemical data, as described in Section 18.6.

In thermodynamics, the equilibrium constant is defined in terms of activities, rather than concentrations. For an ideal mixture, the activity of a substance is the ratio of its concentration (or partial pressure if a gas) to a standard concentration of 1 M (or partial pressure of 1 atm), so that units cancel. Thus, activities have numerical values but no units.

Figure 14.5 ▶

**Some equilibrium compositions for the methanation reaction**

Different starting concentrations have been used in each experiment (all at 1200 K). Experiments 1 and 2 start with different concentrations of reactants CO and H<sub>2</sub>. Experiment 3 starts with the products CH<sub>4</sub> and H<sub>2</sub>O. All three experiments yield essentially the same value of  $K_c$ .

	Starting Concentrations		Equilibrium Concentrations	Calculated Value of $K_c$
<b>Experiment 1</b>	0.1000 M CO 0.3000 M H <sub>2</sub>	→	0.0613 M CO 0.1839 M H <sub>2</sub> 0.0387 M CH <sub>4</sub> 0.0387 M H <sub>2</sub> O	$K_c = 3.93$
<b>Experiment 2</b>	0.2000 M CO 0.3000 M H <sub>2</sub>	→	0.1522 M CO 0.1566 M H <sub>2</sub> 0.0478 M CH <sub>4</sub> 0.0478 M H <sub>2</sub> O	$K_c = 3.91$
<b>Experiment 3</b>	0.1000 M CH <sub>4</sub> 0.1000 M H <sub>2</sub> O	→	0.0613 M CO 0.1839 M H <sub>2</sub> 0.0387 M CH <sub>4</sub> 0.0387 M H <sub>2</sub> O	$K_c = 3.93$

Within the precision of the data, these values (3.93 and 3.91) of the equilibrium expression for different starting mixtures of these gases at 1200 K are the same. Moreover, experiment shows that when you start with CH<sub>4</sub> and H<sub>2</sub>O, instead of CO and H<sub>2</sub>, an equilibrium mixture is again reached that yields the same value of  $K_c$  (see Experiment 3, Figure 14.5). You can take the equilibrium constant for catalytic methanation at 1200 K to be 3.92, the average of these values.

The following exercise provides additional practice in evaluating an equilibrium constant from equilibrium compositions that are experimentally determined. Example 14.3 gives the detailed solution of a more complicated problem of this type.

The reaction described here is used industrially to adjust the ratio of H<sub>2</sub> to CO in synthesis gas (mixture of CO and H<sub>2</sub>). In this process, CO reacts with H<sub>2</sub>O to give H<sub>2</sub>, so the ratio of H<sub>2</sub> to CO is increased.

**Exercise 14.3** When 1.00 mol each of carbon monoxide and water reach equilibrium at 1000°C in a 10.0-L vessel, the equilibrium mixture contains 0.57 mol CO, 0.57 mol H<sub>2</sub>O, 0.43 mol CO<sub>2</sub>, and 0.43 mol H<sub>2</sub>. Write the chemical equation for the equilibrium. What is the value of  $K_c$ ? ◀

See Problems 14.43 and 14.44.

**Example 14.3 Obtaining an Equilibrium Constant from Reaction Composition****Gaining Mastery Toolbox****Critical Concept 14.3**

From the equilibrium amounts of substances in a reaction, calculate the equilibrium constant.

**Solution Essentials:**

- Equilibrium constant,  $K_c$
- Table for change amount in a reaction
- Stoichiometry

Hydrogen iodide, HI, decomposes at moderate temperatures according to the equation

The amount of I<sub>2</sub> in the reaction mixture can be determined from the intensity of the violet color of I<sub>2</sub>; the more intense the color, the more I<sub>2</sub> in the reaction vessel. When 4.00 mol HI was placed in a 5.00-L vessel at 458°C, the equilibrium mixture was found to contain 0.442 mol I<sub>2</sub>. What is the value of  $K_c$  for the decomposition of HI at this temperature?

**Problem Strategy** You will first need to calculate the molar concentrations of substances, because the equilibrium constant is stated in terms of these quantities. The problem statement gives the starting amount of HI and the equilibrium amount of I<sub>2</sub>. As in Example 14.1, it is convenient to set up a table of starting, change, and equilibrium concentrations. You use the equilibrium values to calculate the equilibrium constant  $K_c$ .

(continued)

**Example 14.3** (continued)

**Solution** To obtain the concentrations of HI and I<sub>2</sub>, you divide the molar amounts by the volume of the reaction vessel (5.00 L).

$$\text{Starting concentration of HI} = \frac{4.00 \text{ mol}}{5.00 \text{ L}} = 0.800 \text{ M}$$

$$\text{Equilibrium concentration of I}_2 = \frac{0.442 \text{ mol}}{5.00 \text{ L}} = 0.0884 \text{ M}$$

From these values, you set up the following table:

Concentration (M)	2HI(g)	⇌	H <sub>2</sub> (g)	+	I <sub>2</sub> (g)
Starting	0.800		0		0
Change	-2x		+x		+x
Equilibrium	0.800 - 2x		x		x = 0.0884

The equilibrium concentrations of substances can be evaluated from the expressions given in the last line of this table. You know that the equilibrium concentration of I<sub>2</sub> is 0.0884 M and that this equals x. Therefore,

$$[\text{HI}] = (0.800 - 2x) \text{ M} = (0.800 - 2 \times 0.0884) \text{ M} = 0.623 \text{ M}$$

$$[\text{H}_2] = x = 0.0884 \text{ M}$$

Now you substitute into the equilibrium-constant expression for the reaction. From the chemical equation, you write

$$K_c = \frac{[\text{H}_2][\text{I}_2]}{[\text{HI}]^2}$$

Substituting yields

$$K_c = \frac{(0.0884)(0.0884)}{(0.623)^2} = \mathbf{0.0201}$$

**Answer Check** Arithmetic mistakes are frequent sources of error. If you can obtain even a rough estimate of the answer, you can often spot such errors. For example, suppose the decomposition of HI could go completely to products; then, 4 mol HI would give 2 mol I<sub>2</sub>. The reaction actually gives only a little over 0.4 mol I<sub>2</sub>, which suggests that K<sub>c</sub> is small, probably much less than 1. (Remember, K<sub>c</sub> has products over reactants.) If your calculation gives you something greater than 1, you probably made an arithmetic error. Recheck your calculations.

**Exercise 14.4** Hydrogen sulfide, a colorless gas with a foul odor, dissociates on heating:

When 0.100 mol H<sub>2</sub>S was put into a 10.0-L vessel and heated to 1132°C, it gave an equilibrium mixture containing 0.0285 mol H<sub>2</sub>. What is the value of K<sub>c</sub> at this temperature?

See Problems 14.45, 14.46, 14.47, and 14.48.

## The Equilibrium Constant K<sub>p</sub>

In discussing gas-phase equilibria, it is often convenient to write the equilibrium constant in terms of partial pressures of gases rather than concentrations. Note that the concentration of a gas is proportional to its partial pressure at a fixed temperature (Figure 14.6). You can see this by looking at the ideal gas law,  $PV = nRT$ , and solving for  $n/V$ , which is the molar concentration of the gas. You get  $n/V = P/RT$ .

Figure 14.6 ►

**The concentration of a gas at a given temperature is proportional to the pressure** When the gas is compressed, the pressure increases (as noted from the pressure gauge) and the concentration of the gas (molecules per unit volume) increases.

In other words, the molar concentration of a gas equals its partial pressure divided by  $RT$ , which is constant at a given temperature.

When you express an equilibrium constant for a gaseous reaction in terms of partial pressures, you call it the **equilibrium constant  $K_p$** . For catalytic methanation,

the equilibrium expression in terms of partial pressures becomes

$$K_p = \frac{P_{\text{CH}_4}P_{\text{H}_2\text{O}}}{P_{\text{CO}}P_{\text{H}_2}^3}$$

In general, the value of  $K_p$  is different from that of  $K_c$ . From the relationship for molar concentration  $n/V = P/RT$ , one can show that

$$K_p = K_c(RT)^{\Delta n}$$

where  $\Delta n$  is the sum of the coefficients of *gaseous* products in the chemical equation minus the sum of the coefficients of *gaseous* reactants. For the methanation reaction ( $K_c = 3.92$ ), in which 2 mol of gaseous products ( $\text{CH}_4 + \text{H}_2\text{O}$ ) are obtained from 4 mol of gaseous reactants ( $\text{CO} + 3\text{H}_2$ ),  $\Delta n$  equals  $2 - 4 = -2$ . The usual unit of partial pressures in  $K_p$  is atmospheres; therefore, the value of  $R$  is  $0.0821 \text{ L} \cdot \text{atm}/(\text{K} \cdot \text{mol})$ . Hence,

$$K_p = 3.92 \times (0.0821 \times 1200)^{-2} = 4.04 \times 10^{-4}$$

**Exercise 14.5** Phosphorus pentachloride dissociates on heating:

If  $K_c$  equals  $3.26 \times 10^{-2}$  at  $191^\circ\text{C}$ , what is  $K_p$  at this temperature?

See Problems  
14.51, 14.52,  
14.53, and 14.54.

### Equilibrium Constant for the Sum of Reactions

It is possible to determine the equilibrium constants for various chemical reactions and then use them to obtain the equilibrium constants of other reactions. A useful rule is as follows: *If a given chemical equation can be obtained by taking the sum of other equations, the equilibrium constant for the given equation equals the product of the equilibrium constants of the added equations.*

As an application of this rule, consider the following reactions at 1200 K:

When you take the sum of these two equations, you get

According to the rule, the equilibrium constant for this reaction is  $K_3 = K_1K_2$ . This result is easy to verify. Substituting the expressions for  $K_1$  and  $K_2$  in the product  $K_1K_2$  gives

$$K_1K_2 = \frac{[\text{CH}_4][\text{H}_2\text{O}]}{[\text{CO}][\text{H}_2]^3} \times \frac{[\text{CS}_2][\text{H}_2]^4}{[\text{CH}_4][\text{H}_2\text{S}]^2} = \frac{[\text{CS}_2][\text{H}_2\text{O}][\text{H}_2]}{[\text{CO}][\text{H}_2\text{S}]^2} = K_3$$

which is the equilibrium-constant expression for Reaction 3. The value of the equilibrium constant is  $K_1K_2 = 3.92 \times (3.3 \times 10^4) = 1.3 \times 10^5$ . ▶

You may also use equilibrium expressions in terms of pressures in this calculation.

### CONCEPT CHECK 14.2

Consider the following hypothetical reactions. The equilibrium constants  $K$  given for each reaction are defined in terms of a concentration unit of molecules per liter.

Assume that the reactions have reached equilibrium. Match each of these reactions with one of the containers I to IV (each of which has a volume of 1 L). Identify the “color” of each molecule (for example, is A red or blue?).

## 14.3 Heterogeneous Equilibria; Solvents in Homogeneous Equilibria

A **homogeneous equilibrium** is an equilibrium that involves reactants and products in a single phase. Catalytic methanation is an example of a homogeneous equilibrium; it involves only gaseous reactants and products. On the other hand, a **heterogeneous equilibrium** is an equilibrium involving reactants and products in more than one phase. For example, the reaction of iron metal filings with steam to produce iron oxide,  $\text{Fe}_3\text{O}_4$ , and hydrogen involves solid phases, Fe and  $\text{Fe}_3\text{O}_4$ , in addition to a gaseous phase.

In writing the equilibrium-constant expression for a heterogeneous equilibrium, you omit concentration terms for pure solids and liquids. For the reaction of iron with steam, you would write

$$K_c = \frac{[\text{H}_2]^4}{[\text{H}_2\text{O}]^4}$$

Concentrations of Fe and  $\text{Fe}_3\text{O}_4$  are omitted, because whereas the concentration of a gas can have various values, the concentration of a pure solid or a pure liquid is a constant at a given temperature (because they are relatively incompressible).

To understand why such constant concentrations are omitted in writing  $K_c$ , write the equilibrium-constant expression for the reaction of iron with steam, but include [Fe] and  $[\text{Fe}_3\text{O}_4]$ . Call this  $K'_c$ .

$$K'_c = \frac{[\text{Fe}_3\text{O}_4][\text{H}_2]^4}{[\text{Fe}]^3[\text{H}_2\text{O}]^4}$$

## Daily Life

A CHEMIST Looks at . . .

## Slime Molds and Leopards' Spots

A bright yellow splotch highlights a patch of wood chips in a garden. It looks as if a prankster has poured yellow paint over the chips. Next day the yellow splotch has moved a few inches, and now appears to be climbing up the base of a wall by the garden! A biologist would tell you the yellow splotch is a slime mold (Figure 14.7).

Less noticeable are the cellular slime molds. Much of the time they consist of a group of single-celled amoebas searching for bacteria to eat. But when their food supply is gone, the amoebas release a chemical that signals them to clump together, forming a multicelled slug that moves to a dry, sunlit patch where it forms spores that can be blown to better feeding grounds. During the initial stages of aggregation, the amoebas form a distinctive pattern reminiscent of that seen by chemists in an *oscillating reaction*, which occurs as substances diffuse through a gel (Figure 14.8).

The Russian chemist Boris P. Belousov reported one of the first oscillating reactions in 1958, in which the reaction cycled back and forth over time from one color to another. At first, his work was ignored. You might expect a reaction to form products of a given color, with the reaction gradually slowing as it comes to equilibrium, but how could a chemical reaction oscillate, say, from red to blue and back, over a period of hours? Another Russian chemist, Anatol Zhabotinsky, improved the experiment, leaving no doubt that some

chemical reactions do oscillate. And when the chemicals are placed in a gel in a flat dish, the colors appear as a pattern of waves in space rather than as oscillations in time. Chemists have since shown that the Belousov–Zhabotinsky reaction occurs by two different mechanisms, first by one, then by the other. These mechanisms are repeated in space or time, depending on the concentrations of intermediate substances. During the reaction, an indicator changes color depending on which mechanism is active. Although the complete set of elementary steps of the Belousov–Zhabotinsky reaction is complicated, the overall reaction occurs just as you would expect. The initial reactants continue to decrease over time and the final products increase as the substances come to equilibrium.

An oscillating mechanism also appears to be at work in the aggregation phase of cellular slime molds. And these are not the only biological examples of chemical oscillations. One theory of the formation of fur patterns in animals, such as a leopard's spots, assumes that an oscillating reaction occurs in the skin of the embryo, which eventually generates the fur pattern you see in the adult. A similar theory has been used to explain striped patterns on seashells. The rhythmic beat of your heart is an example where the concentrations of substances oscillate in time. Who would have thought that slime molds, leopards' spots, and cardiac rhythm had anything in common?

Figure 14.8 ▲

**An oscillating reaction** This is a plate showing the wave patterns of the Belousov–Zhabotinsky reaction (in a gel).

■ See Problems 14.113 and 14.114.

You can rearrange the above equation, putting all of the constant factors on the left side.

$$\underbrace{\frac{[\text{Fe}]^3}{[\text{Fe}_3\text{O}_4]}}_{\text{constant factors}} \times K'_c = \underbrace{\frac{[\text{H}_2]^4}{[\text{H}_2\text{O}]^4}}_{\text{variable factors}}$$

Note that all terms on the left are constant but that those on the right (the concentrations of  $\text{H}_2$  and  $\text{H}_2\text{O}$ ) are variable. The left side equals  $K_c$ . Thus, in effect, concentrations of pure solids or pure liquids are incorporated in the value of  $K_c$ . Following similar reasoning, you also omit the concentration of solvent from  $K_c$  for a homogeneous reaction, as long as the concentration of solvent remains essentially constant during reaction. ►

The fact that the concentrations of both Fe and  $\text{Fe}_3\text{O}_4$  do not appear in the equilibrium-constant expression means that the equilibrium is not affected by the amounts of these substances, *as long as some of each is present*.

If you use the thermodynamic equilibrium constant, which is defined in terms of activities, you find that the activity of a pure solid or liquid is 1. Therefore, when you write the equilibrium constant, the activities of pure solids and liquids need not be given explicitly.

### Example 14.4 Writing $K_c$ for a Reaction with Pure Solids or Liquids

#### Gaining Mastery Toolbox

##### Critical Concept 14.4

Pure solids and pure liquids do not appear in the equilibrium-constant expression.

##### Solution Essentials:

- Equilibrium-constant expression,  $K_c$  or  $K_p$
- Balanced equation

- a. Quicklime (calcium oxide,  $\text{CaO}$ ) is prepared by heating a source of calcium carbonate,  $\text{CaCO}_3$ , such as limestone or seashells.

Write the expression for  $K_c$ .

- b. You can write the equilibrium-constant expression for a physical equilibrium, such as vaporization, as well as for a chemical equilibrium. Write the expression for  $K_c$  for the vaporization of water.

**Problem Strategy** Write the equilibrium-constant expression excluding terms for pure solids and liquids.

**Solution** In writing the equilibrium expressions, you ignore pure liquid and solid phases. a.  $K_c = [\text{CO}_2]$ ; b.  $K_c = [\text{H}_2\text{O}(g)]$ .

**Answer Check** The equilibrium-constant expressions should include all reactants and products, except those of pure solids and liquids. Note that the equilibrium between liquid water and water vapor depends only on the vapor (the vapor pressure).

**Exercise 14.6** The Mond process for purifying nickel involves the formation of nickel tetracarbonyl,  $\text{Ni}(\text{CO})_4$ , a volatile liquid, from nickel metal and carbon monoxide. Carbon monoxide is passed over impure nickel to form nickel carbonyl vapor, which, when heated, decomposes and deposits pure nickel.

Write the expression for  $K_c$  for this reaction.

See Problems 14.55 and 14.56.

## ► Using the Equilibrium Constant

In the preceding sections, we described how a chemical reaction reaches equilibrium and how you can characterize this equilibrium by the equilibrium constant. Now we want to see the ways in which an equilibrium constant can be used to answer important questions. We will look at the following uses:

1. *Qualitatively interpreting the equilibrium constant.* By merely looking at the magnitude of  $K_c$ , you can tell whether a particular equilibrium favors products or reactants.
2. *Predicting the direction of reaction.* Consider a reaction mixture that is not at equilibrium. By substituting the concentrations of substances that exist in a reaction mixture into an expression similar to the equilibrium constant and comparing with  $K_c$ , you can predict whether the reaction will proceed toward products or toward reactants (as defined by the way you write the chemical equation).
3. *Calculating equilibrium concentrations.* Once you know the value of  $K_c$  for a reaction, you can determine the composition at equilibrium for any set of starting concentrations.

Let us see what meaning we can attach to the value of  $K_c$ .

### 14.4 Qualitatively Interpreting the Equilibrium Constant

If the value of the equilibrium constant is large, you know immediately that the products are favored at equilibrium. Consider the synthesis of ammonia from its elements.

At 25°C, the equilibrium constant  $K_c$  equals  $4.1 \times 10^8$ . This means that the numerator (related to product concentrations) is  $4.1 \times 10^8$  times larger than the denominator (related to reactant concentrations). In other words, at this temperature the reaction favors the formation of ammonia at equilibrium.

You can verify this by calculating one possible equilibrium composition for this reaction. Suppose the equilibrium mixture is 0.010 *M* in  $\text{N}_2$  and 0.010 *M* in  $\text{H}_2$ . From these concentrations you can calculate the concentration of ammonia necessary to give equilibrium. Substitute the concentrations of  $\text{N}_2$  and  $\text{H}_2$  and the value of  $K_c$  into the equilibrium expression

$$K_c = \frac{[\text{NH}_3]^2}{[\text{N}_2][\text{H}_2]^3}$$

You get

$$\frac{[\text{NH}_3]^2}{(0.010)(0.010)^3} = 4.1 \times 10^8$$

Now you can solve for the concentration of ammonia.

$$[\text{NH}_3]^2 = 4.1 \times 10^8 \times (0.010)(0.010)^3 = 4.1$$

After you take the square root of both sides of this equation, you find that  $[\text{NH}_3] = 2.0$  *M*. The concentrations of  $\text{N}_2$  and  $\text{H}_2$  are both 0.010 *M*, so the amount of ammonia formed at equilibrium is 200 times that of any one reactant. Figure 14.9 shows the burning of methane, a reaction with an enormously large equilibrium constant.

If the value of the equilibrium constant is small, the reactants are favored at equilibrium. As an example, consider the reaction of nitrogen and oxygen to give nitrogen monoxide, NO:

American Gas Association

**Figure 14.9** ▲

**Methane (natural gas) reacts with oxygen** The equilibrium mixture is almost entirely carbon dioxide and water. The equilibrium constant  $K_c$  for the reaction  $\text{CH}_4 + 2\text{O}_2 \rightleftharpoons \text{CO}_2 + 2\text{H}_2\text{O}$  is  $10^{140}$  at 25°C.

The equilibrium constant  $K_c$  equals  $4.6 \times 10^{-31}$  at  $25^\circ\text{C}$ . If you assume that the concentrations of  $\text{N}_2$  and  $\text{O}_2$  are  $1.0\text{ M}$ , you find that the concentration of  $\text{NO}$  is  $6.8 \times 10^{-16}\text{ M}$ . In this case the equilibrium constant is very small, and the concentration of product is not detectable. Reaction occurs to only a very limited extent. ►

When the equilibrium constant is neither large nor small (around 1), neither reactants nor products are strongly favored. The equilibrium mixture contains significant amounts of all substances in the reaction. For example, in the case of the methanation reaction, the equilibrium constant  $K_c$  equals 3.92 at 1200 K. You found that if you start with 1.000 mol  $\text{CO}$  and 3.000 mol  $\text{H}_2$  in a 10.00-L vessel, the equilibrium composition is 0.613 mol  $\text{CO}$ , 1.839 mol  $\text{H}_2$ , 0.387 mol  $\text{CH}_4$ , and 0.387 mol  $\text{H}_2\text{O}$ . Neither the reactants nor the products are predominant.

The equilibrium constant does become large enough at higher temperatures (about  $2000^\circ\text{C}$ ) to give appreciable amounts of nitrogen monoxide (nitric oxide). This is why air ( $\text{N}_2 + \text{O}_2$ ) in flames and in auto engines becomes a source of the pollutant  $\text{NO}$ .

If  $K_c$  for a reaction,

is large, the equilibrium mixture is mostly products. If  $K_c$  is small, the equilibrium mixture is mostly reactants. When  $K_c$  is around 1, the equilibrium mixture contains appreciable amounts of both reactants and products.

**Exercise 14.7** The equilibrium constant  $K_c$  for the reaction

equals  $4.0 \times 10^{13}$  at  $25^\circ\text{C}$ . Does the equilibrium mixture contain predominantly reactants or products? If  $[\text{NO}] = [\text{O}_2] = 2.0 \times 10^{-6}\text{ M}$  at equilibrium, what is the equilibrium concentration of  $\text{NO}_2$ ?

See Problems  
14.57, 14.58,  
14.59, and 14.60.

## 14.5 Predicting the Direction of Reaction

Suppose a gaseous mixture from an industrial plant has the following composition at 1200 K:  $0.0200\text{ M CO}$ ,  $0.0200\text{ M H}_2$ ,  $0.00100\text{ M CH}_4$ , and  $0.00100\text{ M H}_2\text{O}$ . If the mixture is passed over a catalyst at 1200 K, would the reaction

go toward the right or the left? That is, would the mixture form more  $\text{CH}_4$  and  $\text{H}_2\text{O}$  in going toward equilibrium, or more  $\text{CO}$  and  $\text{H}_2$ ?

To answer this question, you substitute the concentrations of substances into the *reaction quotient* and compare its value to  $K_c$ . The **reaction quotient**,  $Q_c$ , is an expression that has the same form as the equilibrium-constant expression but whose concentration values are not necessarily those at equilibrium. For catalytic methanation, the reaction quotient is

$$Q_c = \frac{[\text{CH}_4]_i[\text{H}_2\text{O}]_i}{[\text{CO}]_i[\text{H}_2]_i^3}$$

where the subscript  $i$  indicates concentrations at a particular instant  $i$ . When you substitute the concentrations of the gaseous mixture given above, you get

$$Q_c = \frac{(0.00100)(0.00100)}{(0.0200)(0.0200)^3} = 6.25$$

Recall that the equilibrium constant  $K_c$  for catalytic methanation is 3.92 at 1200 K. For the reaction mixture to go to equilibrium, the value of  $Q_c$  must decrease from 6.25 to 3.92. This will happen if the reaction goes to the left. In that case, the numerator of  $Q_c$  ( $[\text{CH}_4]_i[\text{H}_2\text{O}]_i$ ) will decrease, and the denominator ( $[\text{CO}]_i[\text{H}_2]_i^3$ ) will increase. Thus, the gaseous mixture will give more  $\text{CO}$  and  $\text{H}_2$ .

**Figure 14.10** ▶

**Direction of reaction** The figure shows the relative sizes of  $Q_c$  and  $K_c$ . Reaction proceeds in the direction of the arrows. Thus, on the left,  $Q_c < K_c$ , so the reaction goes to the right, from reactants to products.

Consider the problem more generally. You are given a reaction mixture that is not yet at equilibrium. You would like to know in what direction the reaction will go as it approaches equilibrium. To answer this, you substitute the concentrations of substances from the mixture into the reaction quotient  $Q_c$ . Then, you compare  $Q_c$  to the equilibrium constant  $K_c$ .

For the general reaction  $aA + bB \rightleftharpoons cC + dD$ ,

$$Q_c = \frac{[C]^c [D]^d}{[A]^a [B]^b}$$

Then

If  $Q_c > K_c$ , the reaction will go to the left.  
 If  $Q_c < K_c$ , the reaction will go to the right.  
 If  $Q_c = K_c$ , the reaction mixture is at equilibrium.

(See Figure 14.10.)

### Example 14.5 Using the Reaction Quotient

#### Gaining Mastery Toolbox

##### Critical Concept 14.5

The reaction quotient is an expression with the same form as the equilibrium constant, but whose concentrations are those of the reaction, which may not be at equilibrium.

##### Solution Essentials:

- Reaction quotient
- Equilibrium-constant expression,  $K_c$  or  $K_p$
- Balanced equations

A 50.0-L reaction vessel contains 1.00 mol  $N_2$ , 3.00 mol  $H_2$ , and 0.500 mol  $NH_3$ . Will more ammonia,  $NH_3$ , be formed or will it decompose when the mixture goes to equilibrium at  $400^\circ C$ ? The equation is

$K_c$  is 0.500 at  $400^\circ C$ .

**Problem Strategy** First, write the reaction quotient,  $Q_c$ , which has the same form as the equilibrium-constant expression, but whose concentrations are those for a reaction mixture. Then, compare the value of  $Q_c$  with that of  $K_c$ . If  $Q_c$  is less than  $K_c$ , the reaction goes in the direction written; otherwise it goes in the opposite direction (unless  $Q_c = K_c$ , in which case the reaction is at equilibrium).

**Solution** The composition of the gas has been given in terms of moles. You convert these to molar concentrations by dividing by the volume (50.0 L). This gives 0.0200 M  $N_2$ , 0.0600 M  $H_2$ , and 0.0100 M  $NH_3$ . Substituting these concentrations into the reaction quotient gives

$$Q_c = \frac{[NH_3]_i^2}{[N_2]_i [H_2]_i^3} = \frac{(0.0100)^2}{(0.0200)(0.0600)^3} = 23.1$$

Because  $Q_c = 23.1$  is greater than  $K_c = 0.500$ , the reaction will go to the left as it approaches equilibrium. Therefore, **ammonia will decompose**.

**Answer Check** Here is a check on your result. A reaction tends to go toward equilibrium. This means that  $Q$  goes toward  $K_c$ . If  $Q$  is larger than  $K_c$ , it must become smaller; the top values in  $Q$  (products) need to get smaller, and the bottom values (reactants) need to get larger. Thus, the reaction goes from right to left.

(continued)

**Example 14.5** (continued)

**Exercise 14.8** A 10.0-L vessel contains 0.0015 mol CO<sub>2</sub> and 0.10 mol CO. If a small amount of carbon is added to this vessel and the temperature raised to 1000°C, will more CO form? The reaction is

The value of  $K_c$  is 1.17 at 1000°C. Assume that the volume of gas in the vessel is 10.0 L.

See Problems 14.61 and 14.62.

**CONCEPT CHECK 14.3**

Carbon monoxide and hydrogen react in the presence of a catalyst to form methanol, CH<sub>3</sub>OH:

An equilibrium mixture of these three substances is suddenly compressed so that the concentrations of all substances initially double. In what direction does the reaction go as a new equilibrium is attained?

**14.6 Calculating Equilibrium Concentrations**

Once you have determined the equilibrium constant for a reaction, you can use it to calculate the concentrations of substances in an equilibrium mixture. The next example illustrates a simple type of equilibrium problem.

**Example 14.6 Obtaining One Equilibrium Concentration Given the Others****Gaining Mastery Toolbox****Critical Concept 14.6**

If you have all but one of the concentrations of substances in a chemical equilibrium, you can use the equilibrium constant to calculate this one concentration.

**Solution Essentials:**

- Equilibrium-constant expression,  $K_c$  or  $K_p$
- Balanced equation

A gaseous mixture contains 0.30 mol CO, 0.10 mol H<sub>2</sub>, and 0.020 mol H<sub>2</sub>O, plus an unknown amount of CH<sub>4</sub>, in each liter. This mixture is at equilibrium at 1200 K.

What is the concentration of CH<sub>4</sub> in this mixture? The equilibrium constant  $K_c$  equals 3.92.

**Problem Strategy** Calculate concentrations from moles of substances. Substitute these concentrations into the equilibrium-constant equation and solve for the unknown concentration.

**Solution** The equilibrium-constant equation is

$$K_c = \frac{[\text{CH}_4][\text{H}_2\text{O}]}{[\text{CO}][\text{H}_2]^3}$$

Substituting the known concentrations and the value of  $K_c$  gives

$$3.92 = \frac{[\text{CH}_4](0.020)}{(0.30)(0.10)^3}$$

(continued)

**Example 14.6** (continued)

You can now solve for  $[\text{CH}_4]$ .

$$[\text{CH}_4] = \frac{(3.92)(0.30)(0.10)^3}{(0.020)} = 0.059$$

The concentration of  $\text{CH}_4$  in the mixture is **0.059 mol/L**.

**Answer Check** A simple check is to put the equilibrium concentrations you have calculated into the equilibrium-constant expression. You should obtain the correct value of  $K_c$  (within rounding error).

**Exercise 14.9** Phosphorus pentachloride gives an equilibrium mixture of  $\text{PCl}_5$ ,  $\text{PCl}_3$ , and  $\text{Cl}_2$  when heated.

A 1.00-L vessel contains an unknown amount of  $\text{PCl}_5$  and 0.020 mol each of  $\text{PCl}_3$  and  $\text{Cl}_2$  at equilibrium at  $250^\circ\text{C}$ . How many moles of  $\text{PCl}_5$  are in the vessel if  $K_c$  for this reaction is 0.0415 at  $250^\circ\text{C}$ ?

See Problems  
14.65 and 14.66.

Usually you begin a reaction with known starting quantities of substances and want to calculate the quantities at equilibrium. The next example illustrates the steps used to solve this type of problem.

**Example 14.7 Solving an Equilibrium Problem (Involving a Linear Equation in  $x$ )****Gaining Mastery Toolbox****Critical Concept 14.7**

You use the table of change amounts (involving  $x$  as the change) for an equilibrium mixture to set up the equilibrium constant as an equation in  $x$ .

**Solution Essentials:**

- Solving a linear equation in  $x$
- Equilibrium-constant expression,  $K_c$  or  $K_p$
- Table for change amounts in a reaction (expressing the changes in terms of  $x$ )

The reaction

is used to increase the ratio of hydrogen in synthesis gas (mixtures of  $\text{CO}$  and  $\text{H}_2$ ). Suppose you start with 1.00 mol each of carbon monoxide and water in a 50.0-L vessel. How many moles of each substance are in the equilibrium mixture at  $1000^\circ\text{C}$ ? The equilibrium constant  $K_c$  at this temperature is 0.58.

**Problem Strategy** The solution of an equilibrium problem involves three steps. In Step 1, you use the given information to set up a table of starting, change, and equilibrium concentrations. In this problem, you are given starting amounts of reactants. You use these to obtain the starting concentrations. Express the change concentrations in terms of  $x$ , as we did in Example 14.1. In Step 2, you substitute the equilibrium concentrations in the table into the equilibrium-constant expression and equate this to the value of the equilibrium constant. In Step 3, you solve this equilibrium-constant equation. This example gives an equation that is a perfect square; taking the square root of it gives a linear equation, which is easy to solve. (More generally, an equilibrium equation involves solving an  $n$ th-order equation for its roots. For  $n = 2$ , you can use the quadratic formula, as illustrated in Example 14.8. For  $n > 2$ , it is time to think about using a computer.)

**Solution**

**Step 1:** The starting concentrations of  $\text{CO}$  and  $\text{H}_2\text{O}$  are

$$[\text{CO}] = [\text{H}_2\text{O}] = \frac{1.00 \text{ mol}}{50.0 \text{ L}} = 0.0200 \text{ mol/L}$$

The starting concentrations of the products,  $\text{CO}_2$  and  $\text{H}_2$ , are 0. The changes in concentrations when the mixture goes to equilibrium are not given. However, you can write them all in terms of a single unknown.

(continued)

**Example 14.7** (continued)

If you let  $x$  be the moles of  $\text{CO}_2$  formed per liter, then the moles of  $\text{H}_2$  formed per liter is also  $x$ . Similarly,  $x$  moles each of  $\text{CO}$  and  $\text{H}_2\text{O}$  are consumed. You write the changes for  $\text{CO}$  and  $\text{H}_2\text{O}$  as  $-x$ . You obtain the *equilibrium concentrations* by adding the change in concentrations to the starting concentrations, as shown in the following table:

Concentration (M)	$\text{CO(g)}$	+	$\text{H}_2\text{O(g)}$	$\rightleftharpoons$	$\text{CO}_2\text{(g)}$	+	$\text{H}_2\text{(g)}$
Starting	0.0200		0.0200		0		0
Change	$-x$		$-x$		$+x$		$+x$
Equilibrium	$0.0200 - x$		$0.0200 - x$		$x$		$x$

**Step 2:** You then substitute the values for the equilibrium concentrations into the equilibrium-constant equation,

$$K_c = \frac{[\text{CO}_2][\text{H}_2]}{[\text{CO}][\text{H}_2\text{O}]}$$

and you get

$$0.58 = \frac{(x)(x)}{(0.0200 - x)(0.0200 - x)}$$

or

$$0.58 = \frac{x^2}{(0.0200 - x)^2}$$

**Step 3:** You now solve this equilibrium equation for the value of  $x$ . Note that the right-hand side is a perfect square. If you take the square root of both sides, you get

$$\pm 0.76 = \frac{x}{0.0200 - x}$$

We have written  $\pm$  to indicate that you should consider both positive and negative values, because both are mathematically possible. Rearranging the equation gives

$$x = \frac{0.0200 \times 0.76}{1.76} = 0.0086 \quad \text{and} \quad x = \frac{-0.0200 \times 0.76}{0.24} = -0.063$$

You can dismiss the negative value as physically impossible ( $x$  can be only positive; it represents the concentration of  $\text{CO}_2$  formed). If you substitute for  $x$  in the last line of the table, the equilibrium concentrations are  $0.0114 \text{ M CO}$ ,  $0.0114 \text{ M H}_2\text{O}$ ,  $0.0086 \text{ M CO}_2$ , and  $0.0086 \text{ M H}_2$ . To find the moles of each substance in the 50.0-L vessel, you multiply the concentrations by the volume of the vessel. For example, the amount of  $\text{CO}$  is

$$0.0114 \text{ mol/L} \times 50.0 \text{ L} = 0.570 \text{ mol}$$

The equilibrium composition of the reaction mixture is **0.570 mol CO**, **0.570 mol H<sub>2</sub>O**, **0.43 mol CO<sub>2</sub>**, and **0.43 mol H<sub>2</sub>**.

**Answer Check** A rough estimate of the answer can sometimes save you from giving the wrong answer. If this reaction could go completely to products, 1 mol  $\text{CO}$  could give only 1 mol  $\text{CO}_2$ . (Is the molar amount that you obtained for  $\text{CO}_2$  less than 1?) The magnitude of  $K_c$  suggests that the reaction will give a mixture of approximately similar molar amounts of reactants and products. (Does your answer agree with this?)

**Exercise 14.10** What is the equilibrium composition of a reaction mixture if you start with 0.500 mol each of  $\text{H}_2$  and  $\text{I}_2$  in a 1.0-L vessel? The reaction is

See Problems 14.67 and 14.68.

The preceding example illustrates the three steps used to solve for equilibrium concentrations, as summarized in the following list:

1. Set up a table of concentrations (starting, change, and equilibrium expressions in  $x$ ).
2. Substitute the expressions in  $x$  for equilibrium concentrations into the equilibrium-constant equation.
3. Solve the equilibrium-constant equation for the values of the equilibrium concentrations.

A quadratic equation of the form

$$ax^2 + bx + c = 0$$

has the solutions

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

This equation for  $x$  is called the quadratic formula. (See Appendix A.)

In the previous example, if you had not started with the same number of moles of reactants, you would not have gotten an equation with a perfect square. In that case you would have had to solve a quadratic equation. The next example illustrates how to solve such an equation. ◀

### Example 14.8 Solving an Equilibrium Problem (Involving a Quadratic Equation in $x$ )

#### Gaining Mastery Toolbox

##### Critical Concept 14.8

You use the table of change amounts (involving  $x$  as the change) for an equilibrium mixture to set up the equilibrium constant as an equation in  $x$ .

##### Solution Essentials:

- Solution of a quadratic equation in  $x$
- Equilibrium-constant expression,  $K_c$  or  $K_p$
- Table for change amounts in a reaction (expressing the changes in terms of  $x$ )

Hydrogen and iodine react according to the equation

Suppose 1.00 mol  $\text{H}_2$  and 2.00 mol  $\text{I}_2$  are placed in a 1.00-L vessel. How many moles of each substance are in the gaseous mixture when it comes to equilibrium at  $458^\circ\text{C}$ ? The equilibrium constant  $K_c$  at this temperature is 49.7.

**Problem Strategy** You follow the three-step approach outlined just before this example. The equilibrium equation will be a quadratic equation, which you can solve by the quadratic formula. (See Appendix A for a discussion of this equation and formula.)

#### Solution

**Step 1:** The concentrations of substances are as follows:

Concentration (M)	$\text{H}_2(\text{g})$	+	$\text{I}_2(\text{g})$	$\rightleftharpoons$	$2\text{HI}(\text{g})$
Starting	1.00		2.00		0
Change	$-x$		$-x$		$+2x$
Equilibrium	$1.00 - x$		$2.00 - x$		$2x$

Note that the changes in concentrations equal  $x$  multiplied by the coefficient of that substance in the balanced chemical equation. The change is negative for a reactant and positive for a product. Equilibrium concentrations equal starting concentrations plus the changes in concentrations.

**Step 2:** Substituting into the equilibrium-constant equation,

$$K_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]}$$

you get

$$49.7 = \frac{(2x)^2}{(1.00 - x)(2.00 - x)}$$

(continued)

**Example 14.8** (continued)

**Step 3:** Because the right-hand side is not a perfect square, you must use the quadratic formula to solve for  $x$ . The equation rearranges to give

$$(1.00 - x)(2.00 - x) = (2x)^2/49.7 = 0.0805x^2$$

or 
$$0.920x^2 - 3.00x + 2.00 = 0$$

Hence,

$$x = \frac{3.00 \pm \sqrt{9.00 - 7.36}}{1.84} = 1.63 \pm 0.70$$

A quadratic equation has two mathematical solutions. You obtain one solution by taking the upper (positive) sign in  $\pm$  and the other by taking the lower (negative) sign. You get

$$x = 2.33 \quad \text{and} \quad x = 0.93$$

However,  $x = 2.33$  gives a negative value to  $1.00 - x$  (the equilibrium concentration of  $\text{H}_2$ ), which is physically impossible. Only  $x = 0.93$  remains. You substitute this value of  $x$  into the last line of the table in Step 1 to get the equilibrium concentrations and then multiply these by the volume of the vessel (1.00 L) to get the amounts of substances. The last line of the table is rewritten

The equilibrium composition is **0.07 mol  $\text{H}_2$ , 1.07 mol  $\text{I}_2$ , and 1.86 mol HI.**

**Answer Check** If you substitute the equilibrium concentrations of reactants and product into the equilibrium-constant expression, you should get the value of  $K_c$ . Check that you do.

**Exercise 14.11** Phosphorus pentachloride,  $\text{PCl}_5$ , decomposes when heated.

If the initial concentration of  $\text{PCl}_5$  is 1.00 mol/L, what is the equilibrium composition of the gaseous mixture at  $160^\circ\text{C}$ ? The equilibrium constant  $K_c$  at  $160^\circ\text{C}$  is 0.0211.

See Problems 14.69 and 14.70.

**CONCEPT CHECK 14.4**

A and B react to produce C according to the following chemical equation:

Amounts of A and B are added to an equilibrium reaction mixture of A, B, and C such that when equilibrium is again attained, the amounts of A and B are doubled in the same volume. How is the amount of C changed?

## ► Changing the Reaction Conditions; Le Châtelier's Principle

Obtaining the maximum amount of product from a reaction depends on the proper selection of reaction conditions. By changing these conditions, you can increase or decrease the yield of product. There are three ways to alter the equilibrium composition of a gaseous reaction mixture and possibly increase the yield of product:

1. Changing the concentrations by removing products or adding reactants to the reaction vessel.

2. Changing the partial pressure of gaseous reactants and products by changing the volume.
3. Changing the temperature.

Note that a catalyst cannot alter equilibrium composition, although it can change the rate at which a product is formed.

### 14.7 Removing Products or Adding Reactants

One way to increase the yield of a desired product is to change concentrations in a reaction mixture by removing a product or adding a reactant. Consider the methanation reaction,

If you place 1.000 mol CO and 3.000 mol H<sub>2</sub> in a 10.00-L reaction vessel, the equilibrium composition at 1200 K is 0.613 mol CO, 1.839 mol H<sub>2</sub>, 0.387 mol CH<sub>4</sub>, and 0.387 mol H<sub>2</sub>O. Can you alter this composition by removing or adding one of the substances to improve the yield of methane?

To answer this question, you can apply **Le Châtelier's principle**, which states that *when a system in chemical equilibrium is disturbed by a change of temperature, pressure, or a concentration, the system shifts in equilibrium composition in a way that tends to counteract this change of variable.* ◀ Suppose you remove a substance from or add a substance to the equilibrium mixture in order to alter the concentration of the substance. Chemical reaction then occurs to partially restore the initial concentration of the removed or added substance. (However, if the concentration of substance cannot be changed, as in the case of a pure solid or liquid reactant or product, changes in amount will have no effect on the equilibrium composition.)

For example, suppose that water vapor is removed from the reaction vessel containing the equilibrium mixture for methanation. Le Châtelier's principle predicts that net chemical change will occur to partially reinstate the original concentration of water vapor. This means that the methanation reaction momentarily goes in the forward direction,

until equilibrium is re-established. Going in the forward direction, the concentrations of both water vapor and methane increase.

A practical way to remove water vapor in this reaction would be to cool the reaction mixture quickly to condense the water. Liquid water could be removed and the gases reheated until equilibrium is again established. The concentration of water vapor would build up as the concentration of methane increases. Table 14.1 lists the amounts of each substance at each stage of this process (carried out in a 10.00-L reaction vessel). Note how the yield of methane has been improved.

It is often useful to add an excess of a cheap reactant in order to force the reaction toward more products. In this way, the more expensive reactant is made to react to a greater extent than it would otherwise.

Consider the ammonia synthesis

Le Châtelier's principle was introduced in Section 12.3, where it was used to determine the effect of pressure on solubility of gases in liquids.

**Table 14.1** Effect of Removing Water Vapor from a Methanation Mixture (in a 10.00-L Vessel)

Stage of Process	Mol CO	Mol H <sub>2</sub>	Mol CH <sub>4</sub>	Mol H <sub>2</sub> O
Original reaction mixture	0.613	1.839	0.387	0.387
After removing water (before equilibrium)	0.613	1.839	0.387	0
When equilibrium is reestablished	0.491	1.473	0.509	0.122

**a**

The center beaker contains a reddish orange precipitate of  $\text{HgI}_2$  in equilibrium with  $\text{I}^-$  (colorless) and  $\text{HgI}_4^{2-}$  (pale yellow):  
 $\text{HgI}_2(\text{s}) + 2\text{I}^-(\text{aq}) \rightleftharpoons \text{HgI}_4^{2-}(\text{aq})$ .

**b**

The solution of  $\text{NaI}$  (right beaker) is added to the equilibrium mixture in the center beaker. By adding  $\text{I}^-$ , the reaction is forced to the right:  
 $\text{HgI}_2(\text{s}) + 2\text{I}^-(\text{aq}) \rightarrow \text{HgI}_4^{2-}(\text{aq})$ .  
 The orange precipitate of  $\text{HgI}_2$  disappears.

**c**

A solution of  $\text{NaClO}$  (left beaker) is now added to the reaction mixture; the  $\text{NaClO}$  removes  $\text{I}^-$  by oxidizing it to  $\text{IO}^-$ . By removing  $\text{I}^-$ , the reaction shifts to the left:  
 $\text{HgI}_2(\text{s}) + 2\text{I}^-(\text{aq}) \leftarrow \text{HgI}_4^{2-}(\text{aq})$ .  
 An orange precipitate of  $\text{HgI}_2$  appears.

© Cengage Learning

**Figure 14.11** ▲

**Effect on a chemical equilibrium of changing the concentration of a substance.** The concentration is changed by adding or removing a substance. (The yellow-orange precipitate in c, above, will change in minutes to the red-orange precipitate that you see in a; see Figure 14.14 for an explanation.)

If you wished to convert as much hydrogen to ammonia as possible, you might increase the concentration of nitrogen. To understand the effect of this, first suppose that a mixture of nitrogen, hydrogen, and ammonia is at equilibrium. If nitrogen is now added to this mixture, the equilibrium is disturbed. According to Le Châtelier's principle, the reaction will now go in the direction that will use up some of the added nitrogen.

Consequently, adding more nitrogen has the effect of converting a greater quantity of hydrogen to ammonia. Figure 14.11 illustrates the effect of adding or removing a reactant on another chemical equilibrium.

You can look at these situations in terms of the reaction quotient,  $Q_c$ . Consider the methanation reaction, in which

$$Q_c = \frac{[\text{CH}_4]_i[\text{H}_2\text{O}]_i}{[\text{CO}]_i[\text{H}_2]_i^3}$$

If the reaction mixture is at equilibrium,  $Q_c = K_c$ . Suppose you remove some  $\text{H}_2\text{O}$  from the equilibrium mixture. Now  $Q_c < K_c$ , and from what we said in Section 14.5, you know the reaction will proceed in the forward direction to restore equilibrium.

We can now summarize the conclusions from this section:

When more reactant is added to, or some product is removed from, an equilibrium mixture, thereby changing the concentration of reactant or product, net reaction occurs left to right (that is, in the forward direction) to give a new equilibrium, and more products are produced.

When more product is added to, or some reactant is removed from, an equilibrium mixture, thereby changing the concentration of reactant or product, net reaction occurs right to left (that is, in the reverse direction) to give a new equilibrium, and more reactants are produced.

**Example 14.9 Applying Le Châtelier's Principle When a Concentration Is Altered****Gaining Mastery Toolbox****Critical Concept 14.9**

When the concentration of any substance involved in an equilibrium mixture is altered, the reaction goes in the direction that tends to restore this concentration.

**Solution Essentials:**

- Alteration of amounts of pure solids or liquids has no effect on an equilibrium
- Le Chatelier's principle
- Balanced equation

Predict the direction of reaction when  $\text{H}_2$  is removed from a mixture (lowering its concentration) in which the following equilibrium has been established:

**Problem Strategy** According to Le Châtelier's principle, when you remove a component from an equilibrium mixture, the reaction goes in the direction that tends to restore this component.

**Solution** When  $\text{H}_2$  is removed from the reaction mixture, lowering its concentration, the reaction goes in the **reverse direction** (more HI decomposes to  $\text{H}_2$  and  $\text{I}_2$ ) to partially restore the  $\text{H}_2$  that was removed.

**Answer Check** Make sure that your answer is consistent with Le Châtelier's principle: the component removed (hydrogen in this case) is partially restored by the reaction.

**Exercise 14.12** Consider each of the following equilibria, which are disturbed as indicated. Predict the direction of reaction.

a. The equilibrium

is disturbed by increasing the pressure (that is, concentration) of carbon dioxide.

b. The equilibrium

is disturbed by increasing the concentration of hydrogen.

See Problems 14.73 and 14.74.

A reaction whose equilibrium constant is extremely small remains almost completely as reactants and cannot be shifted to products by adding an excess of one reactant. For example, the reaction

has an equilibrium constant  $K_c$  equal to  $10^{-140}$  at  $25^\circ\text{C}$ . This value is so small that the equilibrium mixture practically consists only of carbon dioxide and water. Adding more carbon dioxide has no appreciable effect.

**14.8 Changing the Pressure and Temperature**

The optimum conditions for catalytic methanation involve moderately elevated temperatures and normal to moderately high pressures.

Let us see whether we can gain insight into why these might be the optimum conditions for the reaction.

**Effect of Pressure Change**

A pressure change *obtained by changing the volume* can affect the yield of product in a gaseous reaction if the reaction involves a change in total moles of gas. The methanation reaction,  $\text{CO} + 3\text{H}_2 \rightleftharpoons \text{CH}_4 + \text{H}_2\text{O}$ , is an example of a change in moles of gas. When the reaction goes in the forward direction, four moles of reactant gas ( $\text{CO} + 3\text{H}_2$ ) become two moles of product gas ( $\text{CH}_4 + \text{H}_2\text{O}$ ).

**Figure 14.12** ▲

**Effect on chemical equilibrium of changing the pressure** The effect on the methanation reaction is shown; the approximate composition is represented by the proportion of different “molecules” (see key at right). The actual arrangement of molecules in a gas is random.

To see the effect of such a pressure change, consider what happens when an equilibrium mixture from the methanation reaction is compressed to one-half of its original volume at a fixed temperature (see Figure 14.12). The total pressure is doubled ( $PV = \text{constant}$  at a fixed temperature, according to Boyle’s law, so halving  $V$  requires that  $P$  double). Because the partial pressures and therefore the concentrations of reactants and products have changed, the mixture is no longer at equilibrium. The direction in which the reaction goes to re-establish equilibrium can be predicted by applying Le Châtelier’s principle. Reaction should go in the forward direction, because then the moles of gas decrease, and the pressure (which is proportional to moles of gas) decreases. In this way, the initial pressure increase is partially reduced.

You find the same result by looking at the reaction quotient  $Q_c$ . Let  $[\text{CO}]$ ,  $[\text{H}_2]$ ,  $[\text{CH}_4]$ , and  $[\text{H}_2\text{O}]$  be the molar concentrations at equilibrium for the methanation reaction. When the volume of an equilibrium mixture is halved, the partial pressures and therefore the concentrations are doubled. You obtain the reaction quotient at that moment by replacing each equilibrium concentration by double its value.

$$Q_c = \frac{(2[\text{CH}_4])(2[\text{H}_2\text{O}])}{(2[\text{CO}])(2[\text{H}_2])^3} = \frac{K_c}{4}$$

Because  $Q_c < K_c$ , the reaction proceeds in the forward direction.

You can see the quantitative effect of the pressure change by solving the equilibrium problem. Recall that if you put 1.000 mol CO and 3.000 mol H<sub>2</sub> into a 10.00-L vessel, the equilibrium composition at 1200 K, where  $K_c$  equals 3.92, is 0.613 mol CO, 1.839 mol H<sub>2</sub>, 0.387 mol CH<sub>4</sub>, and 0.387 mol H<sub>2</sub>O. Suppose the volume of the reaction gases is halved so that the initial concentrations are doubled.

The temperature remains at 1200 K, so  $K_c$  is still 3.92. But if you solve for the new equilibrium composition (following the method of Example 14.8), you obtain 0.495 mol CO, 1.485 mol H<sub>2</sub>, 0.505 mol CH<sub>4</sub>, and 0.505 mol H<sub>2</sub>O. Note that the amount of CH<sub>4</sub> has increased from 0.387 mol to 0.505 mol. You conclude that high pressure of reaction gases favors high yields of methane.

To decide the direction of reaction when the pressure of the reaction mixture is increased (say, by decreasing the volume), you ignore liquids and solids. They are not much affected by pressure changes, because they are nearly incompressible. Consider the reaction

The moles of *gas* increase when the reaction goes in the forward direction (1 mol CO<sub>2</sub> goes to 2 mol CO). Therefore, when you increase the pressure of the reaction mixture by decreasing its volume, the reaction goes in the reverse direction. The moles of gas decrease, and the initial increase of pressure is partially reduced, as Le Châtelier's principle leads you to expect.

It is important to note that an increase or a decrease in pressure of a gaseous reaction must result in changes of partial pressures of substances in the chemical equation if it is to have an effect on the equilibrium composition. Only changes in partial pressures, or concentrations, of these substances can affect the reaction quotient. Consider the effect of increasing the pressure in the methanation reaction by adding helium gas. Although the total pressure increases, the partial pressures of CO, H<sub>2</sub>, CH<sub>4</sub>, and H<sub>2</sub>O do not change. Thus, the equilibrium composition is not affected. However, changing the pressure by changing the volume of this system changes the partial pressures of all gases, so the equilibrium composition is affected.

We can summarize these conclusions:

If the pressure is increased by decreasing the volume of a reaction mixture, the reaction shifts in the direction of fewer moles of gas.

### Example 14.10 Applying Le Châtelier's Principle When the Pressure Is Altered

#### Gaining Mastery Toolbox

##### Critical Concept 14.10

Increasing the gas pressure by decreasing the volume of a reaction mixture shifts the reaction in the direction of fewer moles of gas.

##### Solution Essentials:

- Note whether moles of gases increase or decrease during reaction.
- Le Chatelier's principle
- Balanced equation

Look at each of the following equations and decide whether an increase of pressure obtained by decreasing the volume will increase, decrease, or have no effect on the amounts of products.

- $\text{CO}(g) + \text{Cl}_2(g) \rightleftharpoons \text{COCl}_2(g)$
- $2\text{H}_2\text{S}(g) \rightleftharpoons 2\text{H}_2(g) + \text{S}_2(g)$
- $\text{C}(\text{graphite}) + \text{S}_2(g) \rightleftharpoons \text{CS}_2(g)$

**Problem Strategy** According to Le Châtelier's principle, if you apply pressure to an equilibrium mixture, the reaction goes in the direction to partially offset this applied pressure. Ask whether the molecules of *gas* increase or decrease during reaction from left to right. If they decrease, this should partially offset any increase in applied pressure; the reaction should go from left to right. Otherwise, the reaction should go from right to left.

#### Solution

- Reaction decreases the number of molecules of gas (from two to one). According to Le Châtelier's principle, an increase of pressure **increases** the amount of product.
- Reaction increases the number of molecules of gas (from two to three); hence, an increase of pressure **decreases** the amounts of products.
- Reaction does not change the number of molecules of gas. (You ignore the change in volume due to consumption of solid carbon, because the change in volume of a solid is insignificant. Look only at gas volumes when deciding the effect of pressure change on equilibrium composition.) Pressure change has **no effect**. *(continued)*

**Example 14.10** (continued)

**Answer Check** You look only at the gaseous components when deciding the direction of reaction from an applied pressure. Make sure you have done this correctly.

**Exercise 14.13** Can you increase the amount of product in each of the following reactions by increasing the pressure? Explain.

See Problems  
14.75 and  
14.76.

**Effect of Temperature Change**

Temperature has a profound effect on most reactions. In the first place, reaction rates usually increase with an increase in temperature, meaning that equilibrium is reached sooner. Many gaseous reactions are sluggish or have imperceptible rates at room temperature but speed up enough at higher temperature to become commercially feasible processes.

Second, equilibrium constants vary with temperature. Table 14.2 gives values of  $K_c$  for methanation at various temperatures. Note that  $K_c$  equals  $4.9 \times 10^{27}$  at 298 K. Therefore, an equilibrium mixture at room temperature is mostly methane and water.

Whether you should raise or lower the temperature of a reaction mixture to increase the equilibrium amount of product can be shown by Le Châtelier's principle. Again, consider the methanation reaction,

The value of  $\Delta H^\circ$  shows this reaction to be quite exothermic. As products are formed, considerable heat is released. According to Le Châtelier's principle, as the temperature is raised, the reaction shifts to form more reactants, thereby absorbing heat and "attempting" to counter the increase in temperature.

You predict that the equilibrium constant will be smaller for higher temperatures, in agreement with the values of  $K_c$  given in Table 14.2. Figure 14.13 illustrates the effect of temperature on another chemical equilibrium. ▶

The conclusions from Le Châtelier's principle regarding temperature effects on an equilibrium can be summarized this way:

For an endothermic reaction ( $\Delta H^\circ$  positive), the amounts of products are increased at equilibrium by an increase in temperature ( $K_c$  is larger at higher  $T$ ). For an exothermic reaction ( $\Delta H^\circ$  negative), the amounts of products are increased at equilibrium by a decrease in temperature ( $K_c$  is larger at lower  $T$ ).

**Table 14.2** Equilibrium Constant for Methanation at Different Temperatures

Temperature (K)	$K_c$
298	$4.9 \times 10^{27}$
800	$1.38 \times 10^5$
1000	$2.54 \times 10^2$
1200	3.92

The quantitative effect of temperature on the equilibrium constant is discussed in Chapter 18.

**Example 14.11** Applying Le Châtelier's Principle When the Temperature Is Altered**Gaining Mastery Toolbox****Critical Concept 14.11**

If a reaction evolves heat, that reaction is shifted to the left to absorb heat when the temperature is raised. If the reaction absorbs heat, it shifts to the right when the temperature is raised.

Carbon monoxide is formed when carbon dioxide reacts with solid carbon (graphite).

Is a high or low temperature more favorable to the formation of carbon monoxide?

**Problem Strategy** Decide in which direction you want the reaction to go. (If you want more product, then you want to shift the reaction to the right.) Is this endothermic or exothermic? According to Le Châtelier's principle, if you raise the temperature

(continued)

**Example 14.11** (continued)**Solution Essentials:**

- Raising the temperature shifts reaction away from side where heat appears
- Le Chatelier's principle
- Enthalpy of reaction
- Balanced equation

of an equilibrium mixture, reaction goes in the direction that absorbs heat (that is, it goes in the endothermic direction), to partially offset the heat added for the temperature increase. (Similarly, if you lower the temperature, the reaction goes in the exothermic direction.) Now you can determine whether you must increase or decrease the temperature.

**Solution** You want to increase the yield of CO, so you need to shift the equilibrium toward the right, which is endothermic (absorbs heat). You need to raise the temperature (add heat).

Alternatively, you can look at the problem this way. Write the chemical equation with heat on the left or right, depending on whether the heat is absorbed (consumed) or given off. The reaction to produce CO absorbs heat, so you write the equation with heat on the left.

If you add heat (increasing the temperature), you push the reaction to the right, using up some of that heat.

Thus, **high temperature** is more favorable to the formation of carbon monoxide. This explains why combustion of carbon, or of materials containing carbon, can produce significant amounts of carbon monoxide, in addition to carbon dioxide.

**Answer Check** Check that your answer is consistent with Le Châtelier's principle. If you increase the temperature of the reaction (add heat), the reaction shifts in a direction to use up some of that added heat.

**Exercise 14.14** Consider the possibility of converting carbon dioxide to carbon monoxide by the endothermic reaction

Is a high or a low temperature more favorable to the production of carbon monoxide? Explain.

See Problems  
14.77 and  
14.78.

© Cengage Learning

**Figure 14.13** ▲

**Effect on chemical equilibrium of changing the temperature**

The reaction shown is endothermic:  
 $\text{Co}(\text{H}_2\text{O})_6^{2+}(\text{aq}) + 4\text{Cl}^-(\text{aq}) \rightleftharpoons \text{CoCl}_4^{2-}(\text{aq}) + 6\text{H}_2\text{O}(\text{l})$ . At room temperature, the equilibrium mixture is blue, from  $\text{CoCl}_4^{2-}$ . When cooled by the ice bath, the equilibrium mixture turns pink, from  $\text{Co}(\text{H}_2\text{O})_6^{2+}$ .

✓ **CONCEPT CHECK 14.5**

Given the hypothetical exothermic reaction  $\text{A}_2(\text{g}) + 2\text{B}(\text{g}) \longrightarrow 2\text{AB}(\text{g})$  at equilibrium, decide which of the following containers represents the reaction mixture at the higher temperature? (The other container represents the reaction at a lower temperature.)

**Choosing the Optimum Conditions for Reaction**

You are now in a position to understand the optimum conditions for the methanation reaction. Because the reaction is exothermic, low temperatures should favor high yields of methane; that is, the equilibrium constant is large for low temperature. But gaseous reactions are often very slow at room temperature. In practice, the

methanation reaction is run at moderately elevated temperatures (230°C–450°C) in the presence of a nickel catalyst. Under these conditions, the rate of reaction is sufficiently fast, but the equilibrium constant is not too small. Because the methanation reaction involves a decrease in moles of gas, the yield of methane should increase as the pressure increases. However, the equilibrium constant is large at the usual operating temperatures, so very high pressures are not needed to obtain economical yields of methane. Pressures of 1 atm to 100 atm are usual for this reaction.

As another example, consider the Haber process for the synthesis of ammonia:

Because the reaction is exothermic, the equilibrium constant is larger for lower temperatures. But the reaction proceeds too slowly at room temperature to be practical, even in the presence of the best available catalysts. ▶ The optimum choice of temperature, found experimentally to be about 450°C, is a compromise between an increased rate of reaction at higher temperature and an increased yield of ammonia at lower temperature. Because the formation of ammonia decreases the moles of gases, the yield of product is improved by high pressures. The equilibrium constant  $K_c$  is only 0.159 at 450°C, so higher pressures (about 200 atm) are required for an economical yield of ammonia. Ammonia from the Haber reactor is removed from the reaction mixture by cooling the compressed gases until  $\text{NH}_3$  liquefies. Unreacted  $\text{N}_2$  and  $\text{H}_2$  circulate back to the reactor. See Figure 14.14.

This technological problem has stimulated a great deal of basic research into understanding how certain bacteria “fix” nitrogen at atmospheric pressure to make  $\text{NH}_3$ . An enzyme called nitrogenase is responsible for  $\text{N}_2$  fixation in these bacteria. This enzyme contains Fe and Mo, which may play a catalytic role.

**Exercise 14.15** Consider the reaction

Discuss the temperature and pressure conditions that would give the best yield of carbon monoxide.

See Problems 14.81 and 14.82.

**Figure 14.14** ▲

**Industrial production of ammonia** Shown is a schematic diagram of the production of ammonia from nitrogen (obtained from air) and hydrogen (from natural gas). Input gases ( $\text{N}_2$  and  $\text{H}_2$ ) are compressed to about 200 atm and enter the reactor (the vessel on the left) where they are heated by the exothermic reaction mixture to about 450°C. The hot reaction gas then passes through the porous iron catalyst to give an equilibrium mixture of  $\text{N}_2$ ,  $\text{H}_2$ , and  $\text{NH}_3$ . This mixture exits the reactor and goes to a vessel where it is cooled by water. In the process, steam is produced, which is used to power the compressor and other parts of the ammonia plant. When the reaction gases are sufficiently cooled (at high pressure), the ammonia liquefies. The unreacted  $\text{N}_2$  and  $\text{H}_2$  are recycled back to the reactor.

### 14.9 Effect of a Catalyst

A *catalyst* is a substance that increases the rate of a reaction but is not consumed by it. The significance of a catalyst can be seen in the reaction of sulfur dioxide with oxygen to give sulfur trioxide.

The equilibrium constant  $K_c$  for this reaction is  $1.7 \times 10^{26}$ , which indicates that for all practical purposes the reaction should go almost completely to products. Yet when sulfur is burned in air or oxygen, it forms predominantly  $\text{SO}_2$  and very little  $\text{SO}_3$ . Oxidation of  $\text{SO}_2$  to  $\text{SO}_3$  is simply too slow to give a significant amount of product. However, the rate of the reaction is appreciable in the presence of a platinum or vanadium(V) oxide catalyst. The oxidation of  $\text{SO}_2$  in the presence of a catalyst is the main step in the *contact process* for the industrial production of sulfuric acid,  $\text{H}_2\text{SO}_4$ . Sulfur trioxide reacts with water to form sulfuric acid. (In the industrial process,  $\text{SO}_3$  is dissolved in concentrated  $\text{H}_2\text{SO}_4$ , which is then diluted.) ◀

It is important to understand that *a catalyst has no effect on the equilibrium composition of a reaction mixture. A catalyst merely speeds up the attainment of equilibrium.* For example, suppose you mix 2.00 mol  $\text{SO}_2$  and 1.00 mol  $\text{O}_2$  in a 100.0-L vessel. In the absence of a catalyst, these substances appear unreactive. Much later, if you analyze the mixture, you find essentially the same amounts of  $\text{SO}_2$  and  $\text{O}_2$ . But when a catalyst is added, the rates of both forward and reverse reactions are very much increased. As a result, the reaction mixture comes to equilibrium in a short time. The amounts of  $\text{SO}_2$ ,  $\text{O}_2$ , and  $\text{SO}_3$  can be calculated from the equilibrium constant. You find that the mixture is mostly  $\text{SO}_3$  (2.00 mol), with only  $1.7 \times 10^{-8}$  mol  $\text{SO}_2$  and  $8.4 \times 10^{-9}$  mol  $\text{O}_2$ .

A catalyst is useful for a reaction, such as  $2\text{SO}_2 + \text{O}_2 \rightleftharpoons 2\text{SO}_3$ , that is normally slow but has a large equilibrium constant. However, if the reaction has an exceedingly small equilibrium constant, a catalyst is of little help. The reaction

has been considered for the industrial production of nitric acid. (NO reacts with  $\text{O}_2$  and  $\text{H}_2\text{O}$  to give nitric acid.) At  $25^\circ\text{C}$ , however, the equilibrium constant  $K_c$  equals  $4.6 \times 10^{-31}$ . An equilibrium mixture would contain an extremely small concentration of NO. A catalyst would not provide a significant yield at this temperature; a catalyst merely speeds up the attainment of equilibrium. The equilibrium constant increases as the temperature is raised, so that at  $2000^\circ\text{C}$ , air (a mixture of  $\text{N}_2$  and  $\text{O}_2$ ) forms about 0.4% NO at equilibrium. An industrial plant was set up in Norway in 1905 to prepare nitrate fertilizers using this reaction. The plant was eventually made obsolete by the *Ostwald process* for making nitric acid, in which NO is prepared by the oxidation of ammonia. This latter reaction is more economical than the direct reaction of  $\text{N}_2$  and  $\text{O}_2$ , in part because the equilibrium constant is larger at moderate temperatures.

Although a catalyst cannot affect the composition at true equilibrium, in some cases it can affect the product in a reaction because it affects the rate of one reaction out of several possible reactions. The importance of rate for determining the product in a reaction is illustrated by a simple example in Figure 14.15. Mercury(II) ion reacts with iodide ion to form a precipitate of mercury(II) iodide.

In concentrated solutions, orange tetragonal crystals of  $\text{HgI}_2$  form. In dilute solution, however, yellow rhombic crystals form faster and are the initial product. Later, when true equilibrium is attained, the orange crystals appear.

Sulfur dioxide from the combustion of coal and from other sources appears to be a major cause of the marked increase in acidity of rain in the eastern United States in the past few decades. This acid rain has been shown to contain sulfuric and nitric acids. The  $\text{SO}_2$  is oxidized in moist, polluted air to  $\text{H}_2\text{SO}_4$ . Acid rain is discussed in the essay on acid rain at the end of Section 16.2.

**Figure 14.15** ▲  
An example of how rates of reaction can affect the kind of product

The Ostwald process presents an interesting example of the effect of a catalyst in determining a product when several possibilities exist. Two reactions of ammonia with oxygen are possible. The reaction used in the Ostwald process is

However, nitrogen monoxide decomposes to its elements,

and the equilibrium constant for this is quite large ( $2.2 \times 10^{30}$  at  $25^\circ\text{C}$ ), so at true equilibrium the products of the reaction of ammonia with oxygen might be expected to be nitrogen and water.

Ammonia can be made to burn in oxygen, and  $\text{N}_2$  and  $\text{H}_2\text{O}$  are the products. (The reaction occurs most readily in the presence of a copper catalyst; see Figure 14.16.) However, what Ostwald discovered was that the first reaction, to form  $\text{NO}$  from  $\text{NH}_3$  and  $\text{O}_2$ , is catalyzed by platinum. Therefore, by using this catalyst at moderate temperatures, nitric oxide can be selectively formed. The dissociation of nitric oxide to its elements is normally too slow at moderate temperatures to be significant. Many other examples could be cited in which the products of given reactants depend on the catalyst.

**Figure 14.16** ▲  
**Oxidation of ammonia using a copper catalyst** The products (formed on the glowing copper coil) are  $\text{N}_2$  and  $\text{H}_2\text{O}$ , whereas a platinum catalyst results in  $\text{NO}$  and  $\text{H}_2\text{O}$  as products.

## ✓ A Checklist for Review

### Summary of Facts and Concepts

Chemical equilibrium can be characterized by the *equilibrium constant*  $K_c$ . In the expression for  $K_c$ , the concentration of products is in the numerator and the concentration of reactants is in the denominator. Pure

liquids and solids are ignored in writing the equilibrium-constant expression. When  $K_c$  is very large, the equilibrium mixture is mostly products, and when  $K_c$  is very small, the equilibrium mixture is mostly reactants. The

reaction quotient  $Q_c$  takes the form of the equilibrium-constant expression. If you substitute the concentrations of substances in a reaction mixture into  $Q_c$ , you can predict the direction the reaction must go to attain equilibrium. You can use  $K_c$  to calculate the composition of the reaction mixture at equilibrium, starting from various initial compositions.

The *choice of conditions*, including *catalysts*, can be very important to the success of a reaction. Removing a product from the reaction mixture, for example, shifts the equilibrium composition to give more product. Changing the pressure and temperature can also affect the product yield. *Le Châtelier's principle* is useful in predicting the effect of such changes.

## Learning Objectives

## Important Terms

### 14.1 Chemical Equilibrium—A Dynamic Equilibrium

- Define *dynamic equilibrium* and *chemical equilibrium*.
- Apply stoichiometry to an equilibrium mixture.

**Example 14.1**

**chemical equilibrium**

### 14.2 The Equilibrium Constant

- Define *equilibrium-constant expression* and *equilibrium constant*.
- State the *law of mass action*.
- Write equilibrium-constant expressions. **Example 14.2**
- Describe the kinetics argument for the approach to chemical equilibrium.
- Obtain an equilibrium constant from reaction composition. **Example 14.3**
- Describe the equilibrium constant  $K_p$ ; indicate how  $K_p$  and  $K_c$  are related.
- Obtain  $K_c$  for a reaction that can be written as a sum of other reactions of known  $K_c$  values.

**equilibrium-constant expression**  
**equilibrium constant  $K_c$**   
**equilibrium constant  $K_p$**   
**law of mass action**

### 14.3 Heterogeneous Equilibria; Solvents in Homogeneous Equilibria

- Define *homogeneous equilibrium* and *heterogeneous equilibrium*.
- Write  $K_c$  for a reaction with pure solids or liquids.

**Example 14.4**

**homogeneous equilibrium**  
**heterogeneous equilibrium**

### 14.4 Qualitatively Interpreting the Equilibrium Constant

- Give a qualitative interpretation of the equilibrium constant based on its value.

### 14.5 Predicting the Direction of Reaction

- Define *reaction quotient*,  $Q$ .
- Describe the direction of reaction after comparing  $Q$  with  $K_c$ .
- Use the reaction quotient. **Example 14.5**

**reaction quotient**

### 14.6 Calculating Equilibrium Concentrations

- Obtain one equilibrium concentration given the others. **Example 14.6**
- Solve an equilibrium problem (involving a linear equation in  $x$ ). **Example 14.7**
- Solve an equilibrium problem (involving a quadratic equation in  $x$ ). **Example 14.8**

### 14.7 Removing Products or Adding Reactants

- State *Le Châtelier's principle*.

**Le Châtelier's principle**

- State what happens to an equilibrium when a reactant or product is added or removed.
- Apply Le Châtelier's principle when a concentration is altered. **Example 14.9**

#### 14.8 Changing the Pressure and Temperature

- Describe the effect of a pressure change on chemical equilibrium.
- Apply Le Châtelier's principle when the pressure is altered. **Example 14.10**
- Describe the effect of a temperature change on chemical equilibrium.
- Apply Le Châtelier's principle when the temperature is altered. **Example 14.11**
- Describe how the optimum conditions for a reaction are chosen.

#### 14.9 Effect of a Catalyst

- Define *catalyst*.
- Compare the effect of a catalyst on rate of reaction with its effect on equilibrium.
- Describe how a catalyst can affect the product formed.

### Key Equations

$$K_c = \frac{[C]^c[D]^d}{[A]^a[B]^b} \quad Q_c = \frac{[C]^c[D]^d}{[A]^a[B]^b}$$

## Questions and Problems

### Self-Assessment and Review Questions

**Key:** These questions test your understanding of the ideas you worked with in the chapter. These problems vary in difficulty and often can be used for the basis of discussion.

**14.1** Consider the reaction  $\text{N}_2\text{O}_4(g) \rightleftharpoons 2\text{NO}_2(g)$ . Draw a graph illustrating the changes of concentrations of  $\text{N}_2\text{O}_4$  and  $\text{NO}_2$  as equilibrium is approached. Describe how the rates of the forward and reverse reactions change as the mixture approaches dynamic equilibrium. Why is this called a *dynamic* equilibrium?

**14.2** When 1.0 mol each of  $\text{H}_2(g)$  and  $\text{I}_2(g)$  are mixed at a certain high temperature, they react to give a final mixture consisting of 0.5 mol each of  $\text{H}_2(g)$  and  $\text{I}_2(g)$  and 1.0 mol  $\text{HI}(g)$ . Why do you obtain the same final mixture when you bring 2.0 mol  $\text{HI}(g)$  to the same temperature?

**14.3** Explain why the equilibrium constant for a gaseous reaction can be written in terms of partial pressures instead of concentrations.

**14.4** Obtain the equilibrium constant for the reaction

from the following

**14.5** Which of the following reactions involve homogeneous equilibria and which involve heterogeneous equilibria? Explain the difference.

**14.6** Explain why pure liquids and solids can be ignored when writing the equilibrium-constant expression.

**14.7** What qualitative information can you get from the magnitude of the equilibrium constant?

**14.8** What is the reaction quotient? How is it useful?

**14.9** List the possible ways in which you can alter the equilibrium composition of a reaction mixture.

**14.10** Two moles of  $\text{H}_2$  are mixed with 1 mol  $\text{O}_2$  at  $25^\circ\text{C}$ . No observable reaction takes place, although  $K_c$  for the reaction to form water is very large at this temperature. When a piece of platinum is added, however, the gases react rapidly. Explain the role of platinum in this reaction. How does it affect the equilibrium composition of the reaction mixture?

**14.11** How is it possible for a catalyst to give products from a reaction mixture that are different from those obtained when no catalyst or a different catalyst is used? Give an example.

**14.12** List four ways in which the yield of ammonia in the reaction

can be improved for a given amount of  $\text{H}_2$ . Explain the principle behind each way.

**14.13** A chemist put 1.18 mol of substance A and 2.85 mol of substance B into a 10.0-L flask, which she then closed. A and B react by the following equation:

She found that the equilibrium mixture at  $25^\circ\text{C}$  contained 0.376 mol of D. How many moles of B are in the flask at equilibrium at  $25^\circ\text{C}$ ?

- a 2.47 mol
- b 3.60 mol
- c 2.52 mol
- d 2.10 mol
- e 2.41 mol

**14.14** The reaction  $3\text{A}(\text{g}) + \text{B}(\text{s}) \rightleftharpoons 2\text{C}(\text{aq}) + \text{D}(\text{aq})$  occurs at  $25^\circ\text{C}$  in a flask, which has 1.87 L available for gas. After the reaction attains equilibrium, the amounts (mol) or concentrations ( $M$ ) of substances are as follows:

2.48 mol A	1.13 $M$ C
2.41 mol B	2.27 $M$ D

What is the equilibrium constant  $K_c$  for this reaction at  $25^\circ\text{C}$ ?

- a 1.24
- b 0.190
- c 0.516
- d 1.15
- e 0.939

**14.15** A graduate student places 0.272 mol of  $\text{PCl}_5(\text{g})$  and  $8.56 \times 10^{-4}$  mol of  $\text{PCl}_3(\text{g})$  into a 0.718-L flask at a certain temperature.  $\text{PCl}_5(\text{g})$  is known to decompose as follows:

After the reaction attains equilibrium, the student finds that the flask contains  $2.51 \times 10^{-4}$  mol of  $\text{Cl}_2$ . Calculate the equilibrium constant  $K_c$  for the reaction at this temperature.

- a 0.114
- b  $8.51 \times 10^{-2}$
- c 0.157
- d  $8.88 \times 10^4$
- e  $2.40 \times 10^4$

**14.16** An experimenter places the following concentrations of gases in a closed container:  $[\text{NOBr}] = 7.13 \times 10^{-2} M$ ,  $[\text{NO}] = 1.58 \times 10^{-2} M$ ,  $[\text{Br}_2] = 1.29 \times 10^{-2} M$ . These gases then react:

At the temperature of the reaction, the equilibrium constant  $K_c$  is  $3.07 \times 10^{-4}$ . Calculate the reaction quotient,  $Q_c$ , from the initial concentrations and determine whether the concentration of NOBr increases or decreases as the reaction approaches equilibrium.

- a  $Q_c = 6.33 \times 10^{-4}$ ; the concentration of NOBr decreases
- b  $Q_c = 6.33 \times 10^{-4}$ ; the concentration of NOBr increases
- c  $Q_c = 1.58 \times 10^4$ ; the concentration of NOBr increases
- d  $Q_c = 4.65 \times 10^{-4}$ ; the concentration of NOBr decreases
- e  $Q_c = 4.65 \times 10^{-4}$ ; the concentration of NOBr increases

## Concept Explorations

**Key:** Concept explorations are comprehensive problems that provide a framework that will enable you to explore and learn many of the critical concepts and ideas in each chapter. If you master the concepts associated with these explorations, you will have a better understanding of many important chemistry ideas and will be more successful in solving all types of chemistry problems. These problems are well suited for group work and for use as in-class activities.

### 14.17 Chemical Equilibrium I

**Part 1:** You run the chemical reaction  $\text{C}(\text{aq}) + \text{D}(\text{aq}) \rightleftharpoons 2\text{E}(\text{aq})$  at  $25^\circ\text{C}$ . The equilibrium constant  $K_c$  for the reaction at this temperature is 2.0.

- a Write the equilibrium-constant expression for the reaction.
- b Can you come up with some possible concentrations of C, D, and E that you might observe when the reaction has reached equilibrium at  $25^\circ\text{C}$ ? What are these values?

- c A student says that only a very limited number of concentrations for C, D, and E are possible at equilibrium. Is this true? State why you think this is true or is not true.
- d If you start with 1.0  $M$  concentrations of both C and D and allow the reaction to come to equilibrium, would you expect the concentration of C to have decreased to zero? If not, what would you expect for the concentration of C? (An approximate value is fine.)

**Part 2:** Consider the reaction  $\text{A}(\text{aq}) + \text{B}(\text{aq}) \rightleftharpoons \text{F}(\text{aq}) + \text{G}(\text{aq})$ , whose equilibrium constant is  $1.0 \times 10^{-5}$  at  $20^\circ\text{C}$ . For each of the situations described below, indicate whether any reaction occurs. If reaction does occur, then indicate the direction of that reaction and describe how the concentrations of A, B, F, and G change during this reaction.

- a  $\text{A}(\text{aq})$  and  $\text{B}(\text{aq})$  are mixed together in a container.
- b  $\text{F}(\text{aq})$  and  $\text{G}(\text{aq})$  are mixed together in a container.
- c  $\text{A}(\text{aq})$  and  $\text{F}(\text{aq})$  are mixed together in a container.

- d  $B(aq)$  and  $G(aq)$  are mixed together in a container.  
 e Just  $B(aq)$  is placed into a container.  
 f Just  $G(aq)$  is placed into a container.

Consider any one of these situations in which a reaction does occur. At equilibrium, does the reaction mixture have appreciably more products than reactants? If not, how would you describe the equilibrium composition of the reaction mixture? How did you arrive at this answer?

#### 14.18 Chemical Equilibrium II

Magnesium hydroxide,  $Mg(OH)_2$ , is a white, partially soluble solid that is used in many antacids. The chemical equation for the dissolving of  $Mg(OH)_2(s)$  in water is

- a Describe a simple experimental procedure that you could use to study this solubility equilibrium. In your experiment, how would you determine when the solution process has attained equilibrium?  
 b Write the equilibrium-constant expression for this dissolving of magnesium hydroxide.  
 c Suppose equilibrium has been established in a container of magnesium hydroxide in water, and you decide to add more solid  $Mg(OH)_2$ . What would you expect to observe? What effect will this addition of

$Mg(OH)_2$  have on the concentrations of  $Mg^{2+}(aq)$  and  $OH^{-}(aq)$ ?

- d Say you have prepared an equilibrium solution of  $Mg(OH)_2$  by adding pure solid  $Mg(OH)_2$  to water. If you know the concentration of  $OH^{-}(aq)$ , can you determine the concentration of  $Mg^{2+}(aq)$ ? If not, what information do you need that will allow you to determine the answer?  
 e You slowly add  $OH^{-}$  from another source (say,  $NaOH$ ) to an equilibrium mixture of  $Mg(OH)_2$  and water. How do you expect the concentration of the  $Mg^{2+}(aq)$  to change? What might you be able to observe happening to the  $Mg(OH)_2(s)$  as you add the  $OH^{-}$ ?  
 f Next you remove some, but not all, of the  $Mg(OH)_2(s)$  from the mixture. How will this affect the concentrations of the  $Mg^{2+}(aq)$  and  $OH^{-}(aq)$ ?  
 g If someone hands you a container of  $Mg(OH)_2(aq)$  and there is no solid  $Mg(OH)_2$  present, is this solution at equilibrium? If it is not at equilibrium, what could you add to or remove from the container that would give an equilibrium system?  
 h Consider an individual  $OH^{-}(aq)$  ion in an  $Mg(OH)_2$  solution at equilibrium. If you could follow this ion over a long period of time, would you expect it always to remain as an  $OH^{-}(aq)$  ion, or could it change in some way?

### Conceptual Problems

**Key:** These problems are designed to check your understanding of the concepts associated with some of the main topics presented in each chapter. A strong conceptual understanding of chemistry is the foundation for both applying chemical knowledge and solving chemical problems. These problems vary in level of difficulty and often can be used as a basis for group discussion.

14.19 During an experiment with the Haber process, a researcher put 1 mol  $N_2$  and 1 mol  $H_2$  into a reaction vessel to observe the equilibrium formation of ammonia,  $NH_3$ .

When these reactants come to equilibrium, assume that  $x$  mol  $H_2$  react. How many moles of ammonia form?

14.20 Suppose liquid water and water vapor exist in equilibrium in a closed container. If you add a small amount of liquid water to the container, how does this affect the amount of water vapor in the container? If, instead, you add a small amount of water vapor to the container, how does this affect the amount of liquid water in the container?

14.21 A mixture initially consisting of 2 mol  $CO$  and 2 mol  $H_2$  comes to equilibrium with methanol,  $CH_3OH$ , as the product:

At equilibrium, the mixture will contain which of the following?

- a less than 1 mol  $CH_3OH$   
 b 1 mol  $CH_3OH$

- c more than 1 mol  $CH_3OH$  but less than 2 mol  
 d 2 mol  $CH_3OH$   
 e more than 2 mol  $CH_3OH$

14.22 When a continuous stream of hydrogen gas,  $H_2$ , passes over hot magnetic iron oxide,  $Fe_3O_4$ , metallic iron and water vapor form. When a continuous stream of water vapor passes over hot metallic iron, the oxide  $Fe_3O_4$  and  $H_2$  form. Explain why the reaction goes in one direction in one case but in the reverse direction in the other.

14.23 For the reaction  $2HI(g) \rightleftharpoons H_2(g) + I_2(g)$  carried out at some fixed temperature, the equilibrium constant is 2.0.

- a Which of the following pictures correctly depicts the reaction mixture at equilibrium?  
 b For the pictures that represent nonequilibrium situations, describe which way the reaction will shift to attain equilibrium.

14.24 An experimenter introduces 4.0 mol of gas A into a 1.0-L container at 200 K to form product B according to the reaction

## 519c

## Chemical Equilibrium

Using the experimenter's data (one curve is for A, the other is for B), calculate the equilibrium constant at 200 K.

14.25 The following reaction is carried out at 500 K in a container equipped with a movable piston.

After the reaction has reached equilibrium, the container has the composition depicted here.

Suppose the container volume is doubled.

- How does the equilibrium composition shift?
- How does the concentration of each of the reactants and the product change? (That is, does the concentration increase, decrease, or stay the same?)

14.26 For the endothermic reaction  $AB(g) \rightleftharpoons A(g) + B(g)$ , the following represents a reaction container at two different temperatures. Which one (I or II) is at the lower temperature?

14.27 During the commercial preparation of sulfuric acid, sulfur dioxide reacts with oxygen in an exothermic reaction to produce sulfur trioxide. In this step, sulfur dioxide mixed with oxygen-enriched air passes into a reaction tower at about 420°C, where reaction occurs on a vanadium(V) oxide catalyst. Discuss the conditions used in this reaction in terms of its effect on the yield of sulfur trioxide. Are there any other conditions that you might explore in order to increase the yield of sulfur trioxide?

14.28 At some temperature, a 100-L reaction vessel contains a mixture that is initially 1.00 mol CO and 2.00 mol H<sub>2</sub>. The vessel also contains a catalyst so that the following equilibrium is attained:

At equilibrium, the mixture contains 0.100 mol CH<sub>3</sub>OH (methanol). In a later experiment in the same vessel, you start with 1.00 mol CH<sub>3</sub>OH. How much methanol is there at equilibrium? Explain.

## Practice Problems

**Key:** These problems are for practice in applying problem-solving skills. They are divided by topic, and some are keyed to exercises (see the ends of the exercises). The problems are arranged in matching pairs; the odd-numbered problem of each pair is listed first, and its answer is given in the back of the book.

### Reaction Stoichiometry

14.29 A 2.500-mol sample of phosphorus pentachloride, PCl<sub>5</sub>, decomposes at 160°C and 1.00 atm to give 0.338 mol of phosphorus trichloride, PCl<sub>3</sub>, at equilibrium.

What is the composition of the final reaction mixture?

14.30 You place 4.00 mol of dinitrogen trioxide, N<sub>2</sub>O<sub>3</sub>, into a flask, where it decomposes at 25.0°C and 1.00 atm:

What is the composition of the reaction mixture at equilibrium if it contains 1.20 mol of nitrogen dioxide, NO<sub>2</sub>?

14.31 You place 0.600 mol of nitrogen, N<sub>2</sub>, and 1.800 mol of hydrogen, H<sub>2</sub>, into a reaction vessel at 450°C and 10.0 atm. The reaction is

What is the composition of the equilibrium mixture if you obtain 0.048 mol of ammonia, NH<sub>3</sub>, from it?

14.32 Nitrogen monoxide, NO, reacts with bromine, Br<sub>2</sub>, to give nitrosyl bromide, NOBr.

A sample of 0.0524 mol NO with 0.0262 mol Br<sub>2</sub> gives an equilibrium mixture containing 0.0311 mol NOBr. What is the composition of the equilibrium mixture?

14.33 In the contact process, sulfuric acid is manufactured by first oxidizing SO<sub>2</sub> to SO<sub>3</sub>, which is then reacted with water. The reaction of SO<sub>2</sub> with O<sub>2</sub> is

A 2.000-L flask was filled with 0.0400 mol  $\text{SO}_2$  and 0.0200 mol  $\text{O}_2$ . At equilibrium at 900 K, the flask contained 0.0296 mol  $\text{SO}_3$ . How many moles of each substance were in the flask at equilibrium?

**14.34** Methanol,  $\text{CH}_3\text{OH}$ , formerly known as wood alcohol, is manufactured commercially by the following reaction:

A 1.500-L vessel was filled with 0.1500 mol  $\text{CO}$  and 0.3000 mol  $\text{H}_2$ . When this mixture came to equilibrium at 500 K, the vessel contained 0.1187 mol  $\text{CO}$ . How many moles of each substance were in the vessel?

### The Equilibrium Constant and Its Evaluation

**14.35** Write equilibrium-constant expressions  $K_c$  for each of the following reactions.

- a  $\text{N}_2\text{O}_3(g) \rightleftharpoons \text{NO}_2(g) + \text{NO}(g)$
- b  $2\text{H}_2\text{S}(g) \rightleftharpoons 2\text{H}_2(g) + \text{S}_2(g)$
- c  $2\text{NO}(g) + \text{O}_2(g) \rightleftharpoons 2\text{NO}_2(g)$
- d  $\text{PCl}_3(g) + 3\text{NH}_3(g) \rightleftharpoons \text{P}(\text{NH}_2)_3(g) + 3\text{HCl}(g)$

**14.36** Write equilibrium-constant expressions  $K_c$  for each of the following reactions.

- a  $\text{N}_2\text{H}_4(g) \rightleftharpoons \text{N}_2(g) + 2\text{H}_2(g)$
- b  $2\text{NO}(g) + \text{Cl}_2(g) \rightleftharpoons 2\text{NOCl}(g)$
- c  $2\text{NO}(g) + 2\text{H}_2(g) \rightleftharpoons \text{N}_2(g) + 2\text{H}_2\text{O}(g)$
- d  $2\text{HCl}(g) + \frac{1}{2}\text{O}_2(g) \rightleftharpoons \text{Cl}_2(g) + \text{H}_2\text{O}(g)$

**14.37** The equilibrium-constant expression for a gas reaction is

$$K_c = \frac{[\text{H}_2\text{O}]^2[\text{SO}_2]^2}{[\text{H}_2\text{S}]^2[\text{O}_2]^3}$$

Write the balanced chemical equation corresponding to this expression.

**14.38** The equilibrium-constant expression for a gas reaction is

$$K_c = \frac{[\text{CO}_2]^3[\text{H}_2\text{O}]^4}{[\text{C}_3\text{H}_8][\text{O}_2]^5}$$

Write the balanced chemical equation corresponding to this expression.

**14.39** The equilibrium-constant expression for a reaction is

$$K_c = \frac{[\text{NO}_2]^4[\text{O}_2]}{[\text{N}_2\text{O}_5]^2}$$

What is the equilibrium-constant expression when the equation for this reaction is halved and then reversed?

**14.40** The equilibrium-constant expression for a reaction is

$$K_c = \frac{[\text{NH}_3]^4[\text{O}_2]^5}{[\text{NO}]^4[\text{H}_2\text{O}]^6}$$

What is the equilibrium-constant expression when the equation for this reaction is halved and then reversed?

**14.41** The equilibrium constant  $K_c$  for the equation

at 321°C is 1.03. What is the value of  $K_c$  for the following equation?

**14.42** The equilibrium constant  $K_c$  for the equation

at 900°C is 27.8. What is the value of  $K_c$  for the following equation?

**14.43** A 13.0-L reaction vessel at 499°C contained 0.852 mol  $\text{H}_2$ , 0.361 mol  $\text{I}_2$ , and 3.84 mol  $\text{HI}$ . Assuming that the substances are at equilibrium, find the value of  $K_c$  at 499°C for the reaction of hydrogen and iodine to give hydrogen iodide. The equation is

**14.44** A 4.00-L vessel contained 0.0148 mol of phosphorus trichloride, 0.0126 mol of phosphorus pentachloride, and 0.0870 mol of chlorine at 230°C in an equilibrium mixture. Calculate the value of  $K_c$  for the reaction

**14.45** Obtain the value of  $K_c$  for the following reaction at 900 K:

Use the data given in Problem 14.33.

**14.46** Obtain the value of  $K_c$  for the following reaction at 500 K:

Use the data given in Problem 14.34.

**14.47** At 60°C, 3.76 mol of nitrosyl bromide,  $\text{NOBr}$ , placed in a 1.00-L flask dissociates to the extent of 6.9%; that is, for each mole of  $\text{NOBr}$  before reaction,  $(1.000 - 0.069)$  mol  $\text{NOBr}$  remains after dissociation. Calculate the value of  $K_c$  for the dissociation reaction

**14.48** A 2.00-mol sample of nitrogen dioxide was placed in an 80.0-L vessel. At 200°C, the nitrogen dioxide was 6.0% decomposed according to the equation

Calculate the value of  $K_c$  for this reaction at 200°C. (See Problem 14.47.)

**14.49** Write equilibrium-constant expressions  $K_p$  for each of the following reactions:

- a  $\text{H}_2(g) + \text{Br}_2(g) \rightleftharpoons 2\text{HBr}(g)$
- b  $\text{CS}_2(g) + 4\text{H}_2(g) \rightleftharpoons \text{CH}_4(g) + 2\text{H}_2\text{S}(g)$
- c  $4\text{HCl}(g) + \text{O}_2(g) \rightleftharpoons 2\text{H}_2\text{O}(g) + 2\text{Cl}_2(g)$
- d  $\text{CO}(g) + 2\text{H}_2(g) \rightleftharpoons \text{CH}_3\text{OH}(g)$

**14.50** Write equilibrium-constant expressions  $K_p$  for each of the following reactions:

- a**  $\text{N}_2\text{O}_4(\text{g}) \rightleftharpoons 2\text{NO}_2(\text{g})$   
**b**  $2\text{NOBr}(\text{g}) \rightleftharpoons 2\text{NO}(\text{g}) + \text{Br}_2(\text{g})$   
**c**  $2\text{SO}_3(\text{g}) \rightleftharpoons 2\text{SO}_2(\text{g}) + \text{O}_2(\text{g})$   
**d**  $4\text{NH}_3(\text{g}) + 5\text{O}_2(\text{g}) \rightleftharpoons 4\text{NO}(\text{g}) + 6\text{H}_2\text{O}(\text{g})$

**14.51** The value of  $K_c$  for the following reaction at  $298^\circ\text{C}$  is 41.

What is  $K_p$  at this temperature?

**14.52** The equilibrium constant  $K_c$  equals 0.0952 for the following reaction at  $227^\circ\text{C}$ .

What is the value of  $K_p$  at this temperature?

**14.53** The reaction

has  $K_p$  equal to 6.55 at  $627^\circ\text{C}$ . What is the value of  $K_c$  at this temperature?

**14.54** Fluorine,  $\text{F}_2$ , dissociates into atoms on heating.

The value of  $K_p$  at  $842^\circ\text{C}$  is  $7.55 \times 10^{-2}$ . What is the value of  $K_c$  at this temperature?

**14.55** Write the expression for the equilibrium constant  $K_c$  for each of the following equations:

- a**  $\text{C}(\text{s}) + \text{CO}_2(\text{g}) \rightleftharpoons 2\text{CO}(\text{g})$   
**b**  $\text{FeO}(\text{s}) + \text{CO}(\text{g}) \rightleftharpoons \text{Fe}(\text{s}) + \text{CO}_2(\text{g})$   
**c**  $\text{Na}_2\text{CO}_3(\text{s}) + \text{SO}_2(\text{g}) + \frac{1}{2}\text{O}_2(\text{g}) \rightleftharpoons \text{Na}_2\text{SO}_4(\text{s}) + \text{CO}_2(\text{g})$   
**d**  $\text{PbI}_2(\text{s}) \rightleftharpoons \text{Pb}^{2+}(\text{aq}) + 2\text{I}^{-}(\text{aq})$

**14.56** For each of the following equations, give the expression for the equilibrium constant  $K_c$ :

- a**  $\text{NH}_4\text{Cl}(\text{s}) \rightleftharpoons \text{NH}_3(\text{g}) + \text{HCl}(\text{g})$   
**b**  $\text{C}(\text{s}) + 2\text{N}_2\text{O}(\text{g}) \rightleftharpoons \text{CO}_2(\text{g}) + 2\text{N}_2(\text{g})$   
**c**  $\text{Na}_2\text{CO}_3(\text{s}) + \text{H}_2\text{O}(\text{l}) + \text{CO}_2(\text{g}) \rightleftharpoons 2\text{NaHCO}_3(\text{s})$   
**d**  $\text{Fe}^{3+}(\text{aq}) + 3\text{OH}^{-}(\text{aq}) \rightleftharpoons \text{Fe}(\text{OH})_3(\text{s})$

### Using the Equilibrium Constant

**14.57** On the basis of the value of  $K_c$ , decide whether or not you expect nearly complete reaction at equilibrium for each of the following:

- a**  $\text{N}_2(\text{g}) + \text{O}_2(\text{g}) \rightleftharpoons 2\text{NO}(\text{g}); K_c = 4.6 \times 10^{-31}$   
**b**  $\text{C}_2\text{H}_4(\text{g}) + \text{H}_2(\text{g}) \rightleftharpoons \text{C}_2\text{H}_6(\text{g}); K_c = 1.3 \times 10^{21}$

**14.58** Would either of the following reactions go almost completely to product at equilibrium?

- a**  $2\text{NO}(\text{g}) + 2\text{H}_2(\text{g}) \rightleftharpoons \text{N}_2(\text{g}) + 2\text{H}_2\text{O}(\text{g}); K_c = 6.5 \times 10^{113}$   
**b**  $\text{COCl}_2(\text{g}) \rightleftharpoons \text{CO}(\text{g}) + \text{Cl}_2(\text{g}); K_c = 36 \times 10^{-16}$

**14.59** Hydrogen fluoride decomposes according to the following equation:

The value of  $K_c$  at room temperature is  $1.0 \times 10^{-95}$ . From the magnitude of  $K_c$ , do you think the decomposition occurs to any great extent at room temperature? If an equilibrium mixture in a 1.0-L vessel contains 1.0 mol HF, what is the amount of  $\text{H}_2$  formed? Does this result agree with what you expect from the magnitude of  $K_c$ ?

**14.60** Suppose sulfur dioxide reacts with oxygen at  $25^\circ\text{C}$ .

The equilibrium constant  $K_c$  equals  $8.0 \times 10^{35}$  at this temperature. From the magnitude of  $K_c$ , do you think this reaction occurs to any great extent when equilibrium is reached at room temperature? If an equilibrium mixture is 1.0 M  $\text{SO}_3$  and has equal concentrations of  $\text{SO}_2$  and  $\text{O}_2$ , what is the concentration of  $\text{SO}_2$  in the mixture? Does this result agree with what you expect from the magnitude of  $K_c$ ?

**14.61** The following reaction has an equilibrium constant  $K_c$  equal to  $4.36 \times 10^{-4}$  at  $38^\circ\text{C}$ .

For each of the following compositions, decide whether the reaction mixture is at equilibrium. If it is not, decide which direction the reaction should go.

- a**  $[\text{NOBr}] = 0.0720 \text{ M}, [\text{NO}] = 0.0162 \text{ M}, [\text{Br}_2] = 0.0124 \text{ M}$   
**b**  $[\text{NOBr}] = 0.121 \text{ M}, [\text{NO}] = 0.0159 \text{ M}, [\text{Br}_2] = 0.0139 \text{ M}$   
**c**  $[\text{NOBr}] = 0.103 \text{ M}, [\text{NO}] = 0.0133 \text{ M}, [\text{Br}_2] = 0.0184 \text{ M}$   
**d**  $[\text{NOBr}] = 0.0472 \text{ M}, [\text{NO}] = 0.0121 \text{ M}, [\text{Br}_2] = 0.0105 \text{ M}$

**14.62** The following reaction has an equilibrium constant  $K_c$  equal to 3.59 at  $900^\circ\text{C}$ .

For each of the following compositions, decide whether the reaction mixture is at equilibrium. If it is not, decide which direction the reaction should go.

- a**  $[\text{CH}_4] = 1.26 \text{ M}, [\text{H}_2\text{S}] = 1.32 \text{ M}, [\text{CS}_2] = 1.43 \text{ M}, [\text{H}_2] = 1.12 \text{ M}$   
**b**  $[\text{CH}_4] = 1.25 \text{ M}, [\text{H}_2\text{S}] = 1.52 \text{ M}, [\text{CS}_2] = 1.15 \text{ M}, [\text{H}_2] = 1.73 \text{ M}$   
**c**  $[\text{CH}_4] = 1.30 \text{ M}, [\text{H}_2\text{S}] = 1.41 \text{ M}, [\text{CS}_2] = 1.10 \text{ M}, [\text{H}_2] = 1.20 \text{ M}$   
**d**  $[\text{CH}_4] = 1.56 \text{ M}, [\text{H}_2\text{S}] = 1.43 \text{ M}, [\text{CS}_2] = 1.23 \text{ M}, [\text{H}_2] = 1.91 \text{ M}$

**14.63** Methanol,  $\text{CH}_3\text{OH}$ , is manufactured industrially by the reaction

A gaseous mixture at 500 K is 0.020 M  $\text{CH}_3\text{OH}$ , 0.10 M  $\text{CO}$ , and 0.10 M  $\text{H}_2$ . What will be the direction of reaction if this mixture goes to equilibrium? The equilibrium constant  $K_c$  equals 10.5 at 500 K.

**14.64** Sulfur trioxide, used to manufacture sulfuric acid, is obtained commercially from sulfur dioxide.

The equilibrium constant  $K_c$  for this reaction is  $4.17 \times 10^{-2}$  at  $727^\circ\text{C}$ . What is the direction of reaction when a mixture that is 0.80 M  $\text{SO}_2$ , 0.60 M  $\text{O}_2$ , and 0.10 M  $\text{SO}_3$  approaches equilibrium at  $727^\circ\text{C}$ ?

**14.65** Phosgene,  $\text{COCl}_2$ , used in the manufacture of polyurethane plastics, is prepared from  $\text{CO}$  and  $\text{Cl}_2$ .

An equilibrium mixture at  $395^\circ\text{C}$  contains 0.012 mol  $\text{CO}$  and 0.025 mol  $\text{Cl}_2$  per liter, as well as  $\text{COCl}_2$ . If  $K_c$  at  $395^\circ\text{C}$  is  $1.23 \times 10^3$ , what is the concentration of  $\text{COCl}_2$ ?

**14.66** Nitrogen monoxide, NO, is formed in automobile exhaust by the reaction of N<sub>2</sub> and O<sub>2</sub> (from air).

The equilibrium constant  $K_c$  is 0.0025 at 2127°C. If an equilibrium mixture at this temperature contains 0.023 mol N<sub>2</sub> and 0.031 mol O<sub>2</sub> per liter, what is the concentration of NO?

**14.67** Iodine and bromine react to give iodine monobromide, IBr.

What is the equilibrium composition of a mixture at 145°C that initially contained 0.0019 mol each of iodine and bromine in a 5.0-L vessel? The equilibrium constant  $K_c$  for this reaction at 145°C is 108.

**14.68** Initially a mixture contains 0.850 mol each of N<sub>2</sub> and O<sub>2</sub> in an 8.00-L vessel. Find the composition of the mixture when equilibrium is reached at 3900°C. The reaction is

and  $K_c = 0.0123$  at 3900°C.

**14.69** Calculate the composition of the gaseous mixture obtained when 1.25 mol of carbon dioxide is exposed to hot carbon at 800°C in a 1.25-L vessel. The equilibrium constant  $K_c$  at 800°C is 14.0 for the reaction

**14.70** The equilibrium constant  $K_c$  for the reaction

equals 49 at 230°C. If 0.400 mol each of phosphorus trichloride and chlorine are added to a 4.0-L reaction vessel, what is the equilibrium composition of the mixture at 230°C?

**14.71** Suppose 1.000 mol CO and 3.000 mol H<sub>2</sub> are put in a 10.00-L vessel at 1200 K. The equilibrium constant  $K_c$  for

equals 3.92. Find the equilibrium composition of the reaction mixture.

**14.72** The equilibrium constant  $K_c$  for the reaction

at 450°C is 0.159. Calculate the equilibrium composition when 1.00 mol N<sub>2</sub> is mixed with 3.00 mol H<sub>2</sub> in a 2.00-L vessel.

### Le Châtelier's Principle

**14.73** Consider the equilibrium

When carbon dioxide is removed from the equilibrium mixture (say, by passing the gases through water to absorb CO<sub>2</sub>), what is the direction of net reaction as the new equilibrium is achieved?

**14.74** **a** Predict the direction of reaction when chlorine gas is added to an equilibrium mixture of PCl<sub>3</sub>, PCl<sub>5</sub>, and Cl<sub>2</sub>. The reaction is

**b** What is the direction of reaction when chlorine gas is removed from an equilibrium mixture of these gases?

**14.75** What would you expect to be the effect of an increase of pressure on each of the following reactions? Would the pressure change cause the reaction to go to the right or left?

**14.76** Indicate whether either an increase or a decrease of pressure obtained by changing the volume would increase the amount of product in each of the following reactions.

**14.77** Methanol is prepared industrially from synthesis gas (CO and H<sub>2</sub>).

Would the fraction of methanol obtained at equilibrium be increased by raising the temperature? Explain.

**14.78** One way of preparing hydrogen is by the decomposition of water.

Would you expect the decomposition to be favorable at high or low temperature? Explain.

**14.79** Use thermochemical data (Appendix C) to decide whether the equilibrium constant for the following reaction will increase or decrease with temperature.

**14.80** Use thermochemical data (Appendix C) to decide whether the equilibrium constant for the following reaction will increase or decrease with temperature.

**14.81** What would you expect to be the general temperature and pressure conditions for an optimum yield of nitrogen monoxide, NO, by the oxidation of ammonia?

**14.82** Predict the general temperature and pressure conditions for the optimum conversion of ethylene (C<sub>2</sub>H<sub>4</sub>) to ethane (C<sub>2</sub>H<sub>6</sub>).

## General Problems

**Key:** These problems provide more practice but are not divided by topic or keyed to exercises. Each section ends with essay questions, each of which is color coded to refer to the *A Chemist Looks at Daily Life* (orange) chapter essay on which it is based. Odd-numbered problems and the even-numbered problems that follow are similar; answers to all odd-numbered problems except the essay questions are given in the back of the book.

**14.83** A mixture of carbon monoxide, hydrogen, and methanol,  $\text{CH}_3\text{OH}$ , is at equilibrium according to the equation

At  $290^\circ\text{C}$ , the mixture is  $0.034\text{ M CO}$ ,  $0.450\text{ M H}_2$ , and  $0.00023\text{ M CH}_3\text{OH}$ . What is  $K_c$  for this reaction at  $290^\circ\text{C}$ ?

**14.84** An equilibrium mixture of  $\text{SO}_3$ ,  $\text{SO}_2$ , and  $\text{O}_2$  at  $727^\circ\text{C}$  is  $0.0160\text{ M SO}_3$ ,  $0.0056\text{ M SO}_2$ , and  $0.0021\text{ M O}_2$ . What is the value of  $K_c$  for the following reaction?

**14.85** At  $850^\circ\text{C}$  and  $1.000\text{ atm}$  pressure, a gaseous mixture of carbon monoxide and carbon dioxide in equilibrium with solid carbon is  $90.55\%$   $\text{CO}$  by mass.

Calculate  $K_c$  for this reaction at  $850^\circ\text{C}$ .

**14.86** An equilibrium mixture of dinitrogen tetroxide,  $\text{N}_2\text{O}_4$ , and nitrogen dioxide,  $\text{NO}_2$ , is  $65.8\%$   $\text{NO}_2$  by mass at  $1.00\text{ atm}$  pressure and  $25^\circ\text{C}$ . Calculate  $K_c$  at  $25^\circ\text{C}$  for the reaction

**14.87** A  $2.50\text{-L}$  vessel contains  $1.75\text{ mol N}_2$ ,  $1.75\text{ mol H}_2$ , and  $0.346\text{ mol NH}_3$ . What is the direction of reaction (forward or reverse) needed to attain equilibrium at  $401^\circ\text{C}$ ? The equilibrium constant  $K_c$  for the reaction

is  $0.50$  at  $401^\circ\text{C}$ .

**14.88** A vessel originally contained  $0.0200\text{ mol}$  iodine monobromide ( $\text{IBr}$ ),  $0.050\text{ mol I}_2$ , and  $0.050\text{ mol Br}_2$ . The equilibrium constant  $K_c$  for the reaction

is  $1.2 \times 10^2$  at  $150^\circ\text{C}$ . What is the direction (forward or reverse) needed to attain equilibrium at  $150^\circ\text{C}$ ?

**14.89** A gaseous mixture containing  $1.00\text{ mol}$  each of  $\text{CO}$ ,  $\text{H}_2\text{O}$ ,  $\text{CO}_2$ , and  $\text{H}_2$  is exposed to a zinc oxide–copper oxide catalyst at  $1000^\circ\text{C}$ . The reaction is

and the equilibrium constant  $K_c$  is  $0.58$  at  $1000^\circ\text{C}$ . What is the direction of reaction (forward or reverse) as the mixture attains equilibrium?

**14.90** A  $2.0\text{-L}$  reaction flask initially contains  $0.010\text{ mol CO}$ ,  $0.80\text{ mol H}_2$ , and  $0.50\text{ mol CH}_3\text{OH}$  (methanol).

If this mixture is brought in contact with a zinc oxide–chromium(III) oxide catalyst, the equilibrium

is attained. The equilibrium constant  $K_c$  for this reaction at  $300^\circ\text{C}$  is  $1.1 \times 10^{-2}$ . What is the direction of reaction (forward or reverse) as the mixture attains equilibrium?

**14.91** Hydrogen bromide decomposes when heated according to the equation

The equilibrium constant  $K_c$  equals  $1.6 \times 10^{-2}$  at  $200^\circ\text{C}$ . What are the moles of substances in the equilibrium mixture at  $200^\circ\text{C}$  if we start with  $0.010\text{ mol HBr}$  in a  $1.0\text{-L}$  vessel?

**14.92** Iodine monobromide,  $\text{IBr}$ , occurs as brownish-black crystals that vaporize with decomposition:

The equilibrium constant  $K_c$  at  $100^\circ\text{C}$  is  $0.026$ . If  $0.010\text{ mol IBr}$  is placed in a  $1.0\text{-L}$  vessel at  $100^\circ\text{C}$ , what are the moles of substances at equilibrium in the vapor?

**14.93** Phosgene,  $\text{COCl}_2$ , is a toxic gas used in the manufacture of urethane plastics. The gas dissociates at high temperature.

At  $720^\circ\text{C}$ , the equilibrium constant  $K_c$  is  $3.63 \times 10^{-3}$ . Find the percentage of phosgene that dissociates at this temperature when  $8.60\text{ mol}$  of phosgene is placed in a  $27.1\text{-L}$  vessel.

**14.94** Dinitrogen tetroxide,  $\text{N}_2\text{O}_4$ , is a colorless gas (boiling point,  $21^\circ\text{C}$ ), which dissociates to give nitrogen dioxide,  $\text{NO}_2$ , a reddish brown gas.

The equilibrium constant  $K_c$  at  $25^\circ\text{C}$  is  $0.125$ . What percentage of dinitrogen tetroxide is dissociated when  $0.0400\text{ mol N}_2\text{O}_4$  is placed in a  $1.00\text{-L}$  flask at  $25^\circ\text{C}$ ?

**14.95** Suppose you start with a mixture of  $1.00\text{ mol CO}$  and  $4.00\text{ mol H}_2$  in a  $10.00\text{-L}$  vessel. Find the moles of substances present at equilibrium at  $1200\text{ K}$  for the reaction

You will get an equation of the form

$$f(x) = 3.92$$

where  $f(x)$  is an expression in the unknown  $x$  (the amount of  $\text{CH}_4$ ). Solve this equation by guessing values of  $x$ , then computing values of  $f(x)$ . Find values of  $x$  such that the values of  $f(x)$  bracket  $3.92$ . Then choose values of  $x$  to get a smaller bracket around  $3.92$ . Obtain  $x$  to two significant figures.

**14.96** What are the moles of substances present at equilibrium at  $450^\circ\text{C}$  if  $1.00\text{ mol N}_2$  and  $4.00\text{ mol H}_2$  in a  $10.0\text{-L}$  vessel react according to the following equation?

The equilibrium constant  $K_c$  is 0.153 at 450°C. Use the numerical procedure described in Problem 14.95.

**14.97** The amount of nitrogen dioxide formed by dissociation of dinitrogen tetroxide,

increases as the temperature rises. Is the dissociation of  $\text{N}_2\text{O}_4$  endothermic or exothermic?

**14.98** The equilibrium constant  $K_c$  for the synthesis of methanol,  $\text{CH}_3\text{OH}$ ,

is 4.3 at 250°C and 1.8 at 275°C. Is this reaction endothermic or exothermic?

**14.99** For the reaction

show that  $K_c = K_p(RT)^2$

Do not use the formula  $K_p = K_c(RT)^{\Delta n}$  given in the text. Start from the fact that  $P_i = [i]RT$ , where  $P_i$  is the partial pressure of substance  $i$  and  $[i]$  is its molar concentration. Substitute into  $K_c$ .

**14.100** For the reaction

show that  $K_c = K_p/(RT)$

Do not use the formula  $K_p = K_c(RT)^{\Delta n}$  given in the text. See Problem 14.99.

**14.101** At high temperatures, a dynamic equilibrium exists between carbon monoxide, carbon dioxide, and solid carbon.

At 850°C,  $K_c$  is 0.153.

- What is the value of  $K_p$ ?
- If the original reaction system consisted of just carbon and 1.50 atm of  $\text{CO}_2$ , what are the pressures of  $\text{CO}_2$  and  $\text{CO}$  when equilibrium has been established?
- How will the equilibrium pressure of  $\text{CO}$  change if the temperature is decreased?

**14.102** At high temperatures, a dynamic equilibrium exists between carbon monoxide, carbon dioxide, and solid carbon.

At 900°C,  $K_c$  is 0.238.

- What is the value of  $K_p$ ?
- Some carbon dioxide is added to the hot carbon and the system is brought to equilibrium at 900°C. If the total pressure in the system is 6.80 atm, what are the partial pressures of  $\text{CO}$  and  $\text{CO}_2$ ?
- How will the equilibrium system respond if additional carbon at 900°C is added to the reaction system? Why?

**14.103** The equilibrium constant  $K_c$  for the reaction

equals 4.1 at 300°C.

- A sample of 35.8 g of  $\text{PCl}_5$  is placed in a 5.0-L reaction vessel and heated to 300°C. What are the equilibrium concentrations of all of the species?
- What fraction of  $\text{PCl}_5$  has decomposed?
- If 35.8 g of  $\text{PCl}_5$  were placed in a 1.0-L vessel, what qualitative effect would this have on the fraction of  $\text{PCl}_5$  that has decomposed (give a qualitative answer only; do not do the calculation)? Why?

**14.104** At 25°C in a closed system, ammonium hydrogen sulfide exists as the following equilibrium:

- When a sample of pure  $\text{NH}_4\text{HS}(s)$  is placed in an evacuated reaction vessel and allowed to come to equilibrium at 25°C, the total pressure is 0.660 atm. What is the value of  $K_p$ ?
- To this system, sufficient  $\text{H}_2\text{S}(g)$  is injected until the pressure of  $\text{H}_2\text{S}$  is three times that of the ammonia at equilibrium. What are the partial pressures of  $\text{NH}_3$  and  $\text{H}_2\text{S}$ ?
- In a different experiment, 0.750 atm of  $\text{NH}_3$  and 0.500 atm of  $\text{H}_2\text{S}$  are introduced into a 1.00-L vessel at 25°C. How many moles of  $\text{NH}_4\text{HS}$  are present when equilibrium is established?

**14.105** At moderately high temperatures,  $\text{SbCl}_5$  decomposes into  $\text{SbCl}_3$  and  $\text{Cl}_2$  as follows:

A 65.4-g sample of  $\text{SbCl}_5$  is placed in an evacuated 5.00-L vessel. It is raised to 195°C, and the system comes to equilibrium. If at this temperature 35.8% of the  $\text{SbCl}_5$  is decomposed, what is the value of  $K_p$ ?

**14.106** The following reaction is important in the manufacture of sulfuric acid.

At 900 K, 0.0216 mol of  $\text{SO}_2$  and 0.0148 mol of  $\text{O}_2$  are sealed in a 1.00-L reaction vessel. When equilibrium is reached, the concentration of  $\text{SO}_3$  is determined to be 0.0175 M. Calculate  $K_c$  for this reaction.

**14.107** Sulfuryl chloride is used in organic chemistry as a chlorinating agent. At moderately high temperatures it decomposes as follows:

with  $K_c = 0.045$  at 650 K.

- A sample of 8.25 g of  $\text{SO}_2\text{Cl}_2$  is placed in a 1.00-L reaction vessel and heated to 650 K. What are the equilibrium concentrations of all of the species?
- What fraction of  $\text{SO}_2\text{Cl}_2$  has decomposed?
- If 5 g of chlorine is inserted into the reaction vessel, what qualitative effect would this have on the fraction of  $\text{SO}_2\text{Cl}_2$  that has decomposed?

**14.108** Phosgene was used as a poisonous gas in World War I. At high temperatures it decomposes as follows:

with  $K_c = 4.6 \times 10^{-3}$  at 800 K.

- a A sample of 7.80 g of  $\text{COCl}_2$  is placed in a 1.00-L reaction vessel and heated to 800 K. What are the equilibrium concentrations of all of the species?
- b What fraction of  $\text{COCl}_2$  has decomposed?
- c If 3 g of carbon monoxide is inserted into the reaction vessel, what qualitative effect would this have on the fraction of  $\text{COCl}_2$  that has decomposed?

**14.109** Gaseous acetic acid molecules have a certain tendency to form dimers. (A *dimer* is a molecule formed by the association of two identical, simpler molecules.) The equilibrium constant  $K_c$  at 25°C for this reaction is  $3.2 \times 10^4$ .

- a If the initial concentration of  $\text{CH}_3\text{COOH}$  monomer (the simpler molecule) is  $4.0 \times 10^{-4} M$ , what are the concentrations of monomer and dimer when the system comes to equilibrium? (The simpler quadratic equation is obtained by assuming that all of the acid molecules have dimerized and then some of it dissociates to monomer.)
- b Why do acetic acid molecules dimerize? What type of structure would you draw for the dimer?
- c As the temperature increases, would you expect the percentage of dimer to increase or decrease? Why?

**14.110** Gaseous acetic acid molecules have a certain tendency to form dimers. (A *dimer* is a molecule formed by the association of two identical, simpler molecules.) The equilibrium constant  $K_p$  at 25°C for this reaction is  $1.3 \times 10^3$ .

- a If the initial pressure of  $\text{CH}_3\text{COOH}$  monomer (the simpler molecule) is  $7.5 \times 10^{-3}$  atm, what are the pressures of monomer and dimer when the system comes to equilibrium? (The simpler quadratic equation is obtained by assuming that all of the acid molecules have dimerized and then some of it dissociates to monomer.)
- b Why do acetic acid molecules dimerize? What type of structure would you draw for the dimer?
- c As the temperature decreases, would you expect the percentage of dimer to increase or decrease? Why?

**14.111** When 0.112 mol of NO and 18.22 g of bromine are placed in a 1.00-L reaction vessel and sealed, the mixture is heated to 350 K and the following equilibrium is established:

If the equilibrium concentration of nitrosyl bromide is 0.0824 M, what is  $K_c$ ?

**14.112** When 0.0322 mol of NO and 1.52 g of bromine are placed in a 1.00-L reaction vessel and sealed, the mixture reacts and the following equilibrium is established:

At 25°C the equilibrium pressure of nitrosyl bromide is 0.438 atm. What is  $K_p$ ?

■ **14.113** Oscillating reactions were first reported in 1958. How is it possible for a reaction to oscillate from one color to another?

■ **14.114** In what way are slime molds and leopards' spots related?

## Strategy Problems

**Key:** As noted earlier, all of the practice and general problems are matched pairs. This section is a selection of problems that are not in matched-pair format. These challenging problems require that you employ many of the concepts and strategies that were developed in the chapter. In some cases, you will have to integrate several concepts and operational skills in order to solve the problem successfully.

**14.115** A chemist placed a mixture of  $\text{CO}_2(g)$  and  $\text{CF}_4(g)$  into a flask at a particular temperature. These gases react:

After this mixture came to equilibrium, she found that it contained 0.40 mole fraction of  $\text{CF}_4$  and 0.20 mole fraction of  $\text{COF}_2$ . Calculate  $K_p$  at this temperature for this reaction.

**14.116** You mix equal moles of  $\text{N}_2$ ,  $\text{O}_2$ , and NO and place them into a container fitted with a movable piston. Then you heat the mixture to 2127°C, compressing the mixture with the piston to 10.0 atm, where the following reaction may occur:

$K_p$  for this reaction at 2127°C is 0.0025. Is the mixture of gases initially at equilibrium at this temperature and pressure, or does it undergo reaction to the left or to the

right? Do you have enough information to answer this question? Explain your answer.

**14.117** Consider the mixture described in the previous problem, but suppose it is heated to 3900°C and compressed to 15.0 atm.  $K_p$  at this temperature is 0.0123. What is the equilibrium composition of the mixture? Would it be best to describe this composition in moles or in mole fractions?

**14.118** The equilibrium constant  $K_c$  for the equation

is 1.84 at 425°C. The equilibrium constant  $K_c$  for the equation

is 49.7 at 458°C. Is this second equation endothermic or exothermic? How do you know? Describe the effect on this second equation of an increase in temperature. What would be the effect of an increase in pressure?

**14.119** Consider the reaction  $\text{N}_2\text{O}_4(g) \rightleftharpoons 2\text{NO}_2(g)$ . Would you expect this reaction to be endothermic or exothermic? Why?  $\text{N}_2\text{O}_4$  is a colorless gas;  $\text{NO}_2$  is red-brown. Would you expect a mixture of these gases to become more or less red-brown as you raise the temperature? Explain.

**14.120** A researcher put 0.400 mol  $\text{PCl}_3$  and 0.600 mol  $\text{Cl}_2$  into a 5.00-L vessel at a given temperature to produce phosphorus pentachloride,  $\text{PCl}_5$ :

What will be the composition of this gaseous mixture at equilibrium?  $K_c = 25.6$  at the temperature of this experiment.

**14.121** Ammonium hydrogen sulfide,  $\text{NH}_4\text{HS}$ , is unstable at room temperature and decomposes:

You have placed some solid ammonium hydrogen sulfide in a closed flask. Which of the following would produce less hydrogen sulfide,  $\text{H}_2\text{S}$ , which is a poisonous gas?

- a Removing some  $\text{NH}_3$  from the flask
- b Adding some  $\text{NH}_3$  to the flask
- c Removing some of the  $\text{NH}_4\text{HS}$
- d Increasing the pressure in the flask by adding helium gas

Explain each of your answers.

**14.122** A chemist wants to prepare phosgene,  $\text{COCl}_2$ , by the following reaction:

He places 4.00 g of chlorine,  $\text{Cl}_2$ , and an equal molar amount of carbon monoxide,  $\text{CO}$ , into a 10.00-L reaction vessel at  $395^\circ\text{C}$ . After the reaction comes to equilibrium, he adds another 4.00 g of chlorine to the vessel in order to push the reaction to the right to get more product. What is the partial pressure of phosgene when the reaction again comes to equilibrium?  $K_c = 1.23 \times 10^3$ .

**14.123** Iodine,  $\text{I}_2$ , is a blue-black solid, but it easily vaporizes to give a violet vapor. At high temperatures, this molecular substance dissociates to atoms:

An absent-minded professor measured equilibrium constants for this dissociation at two temperatures,  $700^\circ\text{C}$  and  $800^\circ\text{C}$ . He obtained the  $K_p$  values 0.01106 and 0.001745, but he couldn't remember which value went with what temperature. Can you please help him assign temperatures to the equilibrium constants? State your argument carefully.

**14.124** Nitrogen dioxide,  $\text{NO}_2$ , is a red-brown gas that reacts with itself to produce  $\text{N}_2\text{O}_4$ , a colorless gas:

A flask of "nitrogen dioxide" gas is actually a mixture of  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$ . It is possible to obtain the equilibrium constant  $K_p$  for this reaction from the density of an equilibrium mixture at a given temperature and total pressure. To see how to do that, answer the following questions. (You might find it helpful to refer to the derivation of the equation relating molar mass and density at the end of Section 5.3, on ideal gases.)

- a Use the ideal gas law to obtain an equation at a given  $T$  and  $P$  for the mass of a gas,  $m$ , in terms of its molar mass,  $M_m$ .
- b Suppose you have a mixture of two gases, A and B. Write an equation for the mass of gas A ( $m_A$ ) in terms of the molar mass of A,  $M_{m_A}$ , and its partial pressure,  $P_A$ . Write a similar equation for B. Now write

an equation for the total mass of gas,  $m = m_A + m_B$ . Finally, obtain an equation for the density of the gas mixture,  $d$ , in terms of the partial pressures and molar masses of the components A and B.

- c Let A be  $\text{NO}_2$  and B be  $\text{N}_2\text{O}_4$ . Express the equation you just obtained for the density,  $d$ , in terms of the molar mass,  $M_{m_A}$ , eliminating  $M_{m_B}$ . Also, eliminate  $P_B$  by expressing it in terms of  $P_A$  and  $P$  (total pressure). Now solve this to obtain an equation for  $P_A$ .
- d In an experiment, a chemist discovered that the density of nitrogen dioxide in equilibrium with dinitrogen tetroxide at 1.00 atm and  $35.0^\circ\text{C}$  is 2.86 g/L. What is the equilibrium constant  $K_p$  for the reaction as written at the beginning of this problem?

**14.125** An evacuated 1.000-L flask was filled at room temperature with 0.01308 mol  $\text{NO}$  (nitrogen monoxide) and 0.00559 mol  $\text{Br}_2$  (bromine). The temperature was then raised to  $50.5^\circ\text{C}$ , and these substances reacted to give nitrosyl bromide,  $\text{NOBr}$ :

When equilibrium was achieved, the pressure of the gases in the flask was found to be 0.4027 atm. What was the total moles of gases in the flask at equilibrium? How many moles of nitrosyl bromide were formed? What was the moles of each substance in the flask at equilibrium? What are the partial pressures of the different gases in this equilibrium mixture? What is  $K_p$  at this temperature?

**14.126** A container with a volume of 1.500 L was evacuated and then filled at low temperature with 0.0500 mol liquid dinitrogen tetroxide,  $\text{N}_2\text{O}_4$ . As the temperature was raised, this substance formed nitrogen dioxide,  $\text{NO}_2$ :

If the pressure of this reaction mixture at equilibrium at  $25.0^\circ\text{C}$  was 0.971 atm, what was the total moles of gas in this mixture? What are the moles of  $\text{NO}_2$  and moles of  $\text{N}_2\text{O}_4$ ? What are the partial pressures of  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$ ? What is  $K_p$  at  $25.0^\circ\text{C}$ ?

**14.127** Nitrosyl chloride gas,  $\text{NOCl}$ , was introduced into a 2.000-L flask. The gas was then heated to  $240^\circ\text{C}$ , where it decomposed according to the equation

The pressure was maintained at 1.000 atm by a piston mechanism attached to the flask. When the gas reached equilibrium, it was analyzed and found to contain 0.404 g chlorine gas,  $\text{Cl}_2$ , in the 2.00-L flask. What is the equilibrium constant  $K_p$  for the reaction?

**14.128** The major constituents of the atmosphere are nitrogen,  $\text{N}_2$ , and oxygen,  $\text{O}_2$ . Dry atmospheric air at a pressure of 1.000 atm has a partial pressure of  $\text{N}_2$  of 0.781 atm and a partial pressure of  $\text{O}_2$  of 0.209 atm. At high temperatures,  $\text{N}_2$  and  $\text{O}_2$  react to produce nitrogen monoxide (nitric oxide),  $\text{NO}$ .

Suppose a sample of dry air is raised to  $2127^\circ\text{C}$  in a hot flame and then rapidly cooled to fix the amount of  $\text{NO}$  formed. If  $K_p$  for this reaction at this temperature is 0.0025, how many grams of  $\text{NO}$  would be produced from 100.0 g of dry air?

**14.129** Iodine,  $I_2$ , and bromine,  $Br_2$ , react to produce iodine monobromide,  $IBr$ .

A starting mixture of 0.5000 mol  $I_2$  and 0.5000 mol  $Br_2$  reacts at  $150^\circ C$  to produce 0.4221 mol  $IBr$  at equilibrium. What would be the equilibrium composition (in moles) of a mixture that starts with 1.000 mol  $I_2$  and 2.000 mol  $Br_2$ ?

**14.130** Sulfur dioxide reacts with oxygen to produce sulfur trioxide in the presence of a catalyst:

In an experiment carried out at  $727^\circ C$ , the partial pressures of  $SO_2$  and  $O_2$  at equilibrium were found to be 0.721 atm and 0.581 atm, respectively, with a total pressure of 2.325 atm. What is the value of  $K_p$  for this reaction at this temperature? What would be the effect of an increase in pressure on the amount of  $SO_3$  produced? What would be the effect of an increase in temperature on the amount of  $SO_3$  produced? (Use relevant data from Appendix C.) Explain your answers.

**14.131** Molecular bromine,  $Br_2$ , dissociates at elevated temperatures into bromine atoms,  $Br$ .

A 3.000-L flask initially contains pure molecular bromine. The temperature is then raised to 1600 K. If the total pressure of this equilibrium mixture at this elevated temperature is 1.000 atm, what are the total moles of gas in the container? A spectroscopic analysis of this mixture showed that it contained 1.395 g of  $Br$  atoms. What is the partial pressure of  $Br$ ? What is  $K_p$  for the dissociation of molecular bromine to bromine atoms?

**14.132** Consider the production of ammonia from its elements:

In a pilot experiment, a mixture of 1.00 part nitrogen gas and 3.00 parts hydrogen gas at a total pressure of 10.00 atm was passed through a hot tube over a catalyst at  $450.0^\circ C$ . What are the total moles of gas in a 1.000-L volume of this equilibrium mixture? If the equilibrium mixture contains a partial pressure of 0.204 atm of ammonia, how many moles of ammonia are in this 1.000-L volume? How many moles of  $N_2$  are in this same volume? What is the partial pressure of  $N_2$  in this equilibrium mixture? What is the equilibrium constant  $K_p$  for this reaction?

**14.133** A mixture of 0.0565 mol phosphorus pentachloride,  $PCl_5$ , and 0.0800 mol helium gas,  $He$ , was placed in a 1.000-L flask and heated to  $250.0^\circ C$ . The phosphorus pentachloride decomposes at this temperature to give phosphorus trichloride,  $PCl_3$ , and chlorine gas,  $Cl_2$ . The helium gas is inert.

What is the partial pressure of helium in this equilibrium mixture at  $250.0^\circ C$ ? At equilibrium, the total pressure is found to be 6.505 atm. What is  $K_c$  for the dissociation of  $PCl_5$ ?

**14.134** Calcium carbonate,  $CaCO_3$ , decomposes when heated to give calcium oxide,  $CaO$ , and carbon dioxide,  $CO_2$ .

$K_p$  for this reaction at  $900^\circ C$  is 1.040. What would be the yield of carbon dioxide (in grams) when 1.000 g of  $CaCO_3$  and 1.000 g  $CaO$  are heated to  $900^\circ C$  in a 1.000-L vessel. (Ignore the volume occupied by the solids.) What would be the effect of adding a similar quantity of carbon dioxide to this equilibrium mixture? What would happen if the quantity of calcium carbonate were doubled?

## Capstone Problems

**Key:** The problems under this heading combine skills, strategies, and concepts learned in previous chapters with those introduced in the current one.

**14.135** The following equilibrium was studied by analyzing the equilibrium mixture for the amount of  $H_2S$  produced.

A vessel whose volume was 2.50 L was filled with 0.0100 mol of antimony(III) sulfide,  $Sb_2S_3$ , and 0.0100 mol  $H_2$ . After the mixture came to equilibrium in the closed vessel at  $440^\circ C$ , the gaseous mixture was removed, and the hydrogen sulfide was dissolved in water. Sufficient lead(II) ion was added to react completely with the  $H_2S$  to precipitate lead(II) sulfide,  $PbS$ . If 1.029 g  $PbS$  was obtained, what is the value of  $K_c$  at  $440^\circ C$ ?

**14.136** The following equilibrium was studied by analyzing the equilibrium mixture for the amount of  $HCl$  produced.

A vessel whose volume was 1.25 L was filled with 0.0125 mol of lanthanum(III) chloride,  $LaCl_3$ , and 0.0250 mol  $H_2O$ .

After the mixture came to equilibrium in the closed vessel at  $619^\circ C$ , the gaseous mixture was removed and dissolved in more water. Sufficient silver ion was added to precipitate the chloride ion completely as silver chloride. If 3.59 g  $AgCl$  was obtained, what is the value of  $K_c$  at  $619^\circ C$ ?

**14.137** Phosphorus pentachloride,  $PCl_5$ , decomposes on heating to give phosphorus trichloride,  $PCl_3$ , and chlorine.

A closed 2.90-L vessel initially contains 0.0564 mol  $PCl_5$ . What is the total pressure at  $250^\circ C$  when equilibrium is achieved? The value of  $K_c$  at  $250^\circ C$  is  $4.15 \times 10^{-2}$ .

**14.138** Antimony(V) chloride,  $SbCl_5$ , decomposes on heating to give antimony(III) chloride,  $SbCl_3$ , and chlorine.

A closed 3.50-L vessel initially contains 0.0125 mol  $SbCl_5$ . What is the total pressure at  $248^\circ C$  when equilibrium is achieved? The value of  $K_c$  at  $248^\circ C$  is  $2.50 \times 10^{-2}$ .

## 15

## Acids and Bases

Red cabbage juice is green in basic solution (left beaker) but turns red when dry ice, solid  $\text{CO}_2$ , is added (center) to give an acidic solution (right).

## CONTENTS AND CONCEPTS

**Acid–Base Concepts**

Svante Arrhenius was the first to explain that *acids* were substances that produce hydrogen ion,  $\text{H}^+(\text{aq})$ , when dissolved in water. Later, Johannes Brønsted and Thomas Lowry explained that *acid–base reactions* are proton-transfer reactions. We look at these ideas in the first sections of this chapter.

**15.1** Arrhenius Concept of Acids and Bases

**15.2** Brønsted–Lowry Concept of Acids and Bases

**15.3** Lewis Concept of Acids and Bases

**Acid and Base Strengths**

From the Brønsted–Lowry view, it is useful to think of acid–base reactions as a competition between different species for protons. Then you can order acids

(and bases) by their relative strengths. This idea is expanded on in the next two sections.

**15.4** Relative Strengths of Acids and Bases

**15.5** Molecular Structure and Acid Strength

**Autoionization of Water and pH**

The dominant ions in water solution are the hydronium ion  $\text{H}_3\text{O}^+$  (also described

as the hydrogen ion  $\text{H}^+$ ) and the hydroxide ion  $\text{OH}^-$ , which result from the dissociation or *autoionization* of water. This autoionization is characterized in terms of the concept of pH. The autoionization of water and the concept of pH are discussed in the next sections.

**15.6** Autoionization of Water

**15.7** Solutions of a Strong Acid or Base

**15.8** The pH of a Solution

**A**cids and bases were first recognized by simple properties, such as taste. Acids have a sour taste; bases are bitter. Also, acids and bases change the color of certain dyes called indicators, such as litmus and phenolphthalein. Acids change litmus from blue to red and basic phenolphthalein from red to colorless. Bases change litmus from red to blue and phenolphthalein from colorless to red. As you can see from these color changes, acids and bases neutralize, or reverse, the action of one another. During neutralization, acids and bases react with each other to produce ionic substances called salts. Acids react with active metals, such as magnesium and zinc, to release hydrogen.

The Swedish chemist Svante Arrhenius framed the first successful concept of acids and bases. He defined acids and bases in terms of the effect these substances have on water. According to Arrhenius, acids are substances that increase the concentration of  $\text{H}^+$  ion in aqueous solution, and bases increase the concentration of  $\text{OH}^-$  ion in aqueous solution. But many reactions that have characteristics of acid–base reactions in aqueous solution occur in other solvents or without a solvent. For example, hydrochloric acid reacts with aqueous ammonia, which in the Arrhenius view is a base because it increases the concentration of  $\text{OH}^-$  ion in aqueous solution. The reaction can be written

The product is a solution of  $\text{NH}_4\text{Cl}$ —that is, a solution of  $\text{NH}_4^+$  and  $\text{Cl}^-$  ions. A very similar reaction occurs between hydrogen chloride and ammonia dissolved in benzene,  $\text{C}_6\text{H}_6$ . The product is again  $\text{NH}_4\text{Cl}$ , which in this case precipitates from the solution.

Hydrogen chloride and ammonia react even in the gas phase. If watch glasses (shallow glass dishes) of concentrated hydrochloric acid and concentrated ammonia are placed next to each other, dense, white fumes of  $\text{NH}_4\text{Cl}$  particles form where  $\text{HCl}$  gas and  $\text{NH}_3$  gas come into contact (Figure 15.1).

These reactions of  $\text{HCl}$  and  $\text{NH}_3$ , in benzene and in the gas phase, are similar to the reaction in aqueous solution but cannot be explained by the Arrhenius concept. Broader acid–base concepts are needed.

In the first part of this chapter, we will discuss the Arrhenius, the Brønsted–Lowry, and the Lewis concepts of acids and bases. The Brønsted–Lowry and Lewis concepts apply to nonaqueous as well as aqueous solutions and also go beyond the Arrhenius concept in other ways. This chapter expands on what you learned in Chapter 4 about acids and bases.

## ► Acid–Base Concepts

Antoine Lavoisier was one of the first chemists to try to explain what makes a substance acidic. In 1777 he proposed that oxygen was an essential element in acids. (*Oxygen*, which he named, means “acid-former” in Greek.) But in 1808 Humphry Davy showed that hydrogen chloride, which dissolves in water to give hydrochloric acid, contains only hydrogen and chlorine. Although some chemists argued that chlorine was a compound of oxygen, chlorine was eventually proved to be an element. Chemists then noted that hydrogen, not oxygen, must be the essential constituent of acids. The cause of acidity and basicity was first explained in 1884 by Svante Arrhenius.

### 15.1 Arrhenius Concept of Acids and Bases

We can state the Arrhenius concept of an acid as follows: *An acid is a substance that, when dissolved in water, increases the concentration of hydronium ion,  $\text{H}_3\text{O}^+(aq)$ .* For simplicity, chemists frequently use the notation  $\text{H}^+(aq)$  for the  $\text{H}_3\text{O}^+(aq)$  ion and call

Figure 15.1 ▲

**Reaction of  $\text{HCl}(g)$  and  $\text{NH}_3(g)$  to form  $\text{NH}_4\text{Cl}(s)$**  Gases from the concentrated solutions diffuse from their watch glasses (shallow dishes) and react to give a smoke of ammonium chloride particles.

This section summarizes the discussion in section 4.4.

Figure 15.2 ▲

**The hydronium ion,  $\text{H}_3\text{O}^+$**  The species is shown here hydrogen-bonded to three water molecules. The positive charge shown is actually distributed over the ion.

We introduced strong and weak acids and bases in Section 4.4.

Table 15.1 Common Strong Acids and Bases

Strong Acids	Strong Bases*
$\text{HClO}_4$	$\text{LiOH}$
$\text{H}_2\text{SO}_4$	$\text{NaOH}$
$\text{HI}$	$\text{KOH}$
$\text{HBr}$	$\text{Ca}(\text{OH})_2$
$\text{HCl}$	$\text{Sr}(\text{OH})_2$
$\text{HNO}_3$	$\text{Ba}(\text{OH})_2$

\*In general, the Group 1A and Group 2A hydroxides (except beryllium hydroxide) are strong bases.

it the hydrogen ion. Remember, however, that the aqueous hydrogen ion is not a bare proton in water, but a proton chemically bonded to water—that is,  $\text{H}_3\text{O}^+(\text{aq})$ . The  $\text{H}_3\text{O}^+(\text{aq})$  ion is itself associated through hydrogen bonding with a variable number of water molecules. One such species is shown in Figure 15.2. A base, in the Arrhenius concept, is a substance that, when dissolved in water, increases the concentration of hydroxide ion,  $\text{OH}^-(\text{aq})$ . ◀

The special role of the hydronium ion (or hydrogen ion) and the hydroxide ion in aqueous solutions arises from the following reaction:

The addition of acids and bases alters the concentrations of these ions in water.

In Arrhenius's theory, a *strong acid* is a substance that completely ionizes in aqueous solution to give  $\text{H}_3\text{O}^+(\text{aq})$  and an anion. An example is perchloric acid,  $\text{HClO}_4$ .

Other examples of strong acids are  $\text{H}_2\text{SO}_4$ ,  $\text{HI}$ ,  $\text{HBr}$ ,  $\text{HCl}$ , and  $\text{HNO}_3$ . A *strong base* completely ionizes in aqueous solution to give  $\text{OH}^-$  and a cation. Sodium hydroxide is an example of a strong base.

The principal strong bases are the hydroxides of Group 1A elements and Group 2A elements (except Be). See Table 15.1. ◀

Most of the other acids and bases you encounter are *weak*. They are not completely ionized in solution and exist in reversible reaction with the corresponding ions. Consider acetic acid,  $\text{HC}_2\text{H}_3\text{O}_2$ . The reaction with water is

Evidence for the Arrhenius theory comes from the heat of reaction,  $\Delta H^\circ$ , for the neutralization of a strong acid by a strong base. This neutralization is essentially the reaction of  $\text{H}_3\text{O}^+(\text{aq})$  with  $\text{OH}^-(\text{aq})$  and should therefore always give the same  $\Delta H^\circ$  per mole of water formed. For example, if you write the neutralization of  $\text{HClO}_4$  with  $\text{NaOH}$  in ionic form, you have

After canceling, you get the net ionic equation

Experimentally, it is found that all neutralizations involving strong acids and bases have the same  $\Delta H^\circ$ :  $-55.90 \text{ kJ per mole of H}^+$ . This indicates that the same reaction occurs in each neutralization, as Arrhenius's theory predicts.

Despite its successes, the Arrhenius concept is limited. In addition to looking at acid–base reactions only in aqueous solutions, it singles out the  $\text{OH}^-$  ion as the source of base character, when other species can play a similar role. Broader definitions of acids and bases are described in the next sections.

## 15.2 Brønsted–Lowry Concept of Acids and Bases

In 1923 the Danish chemist Johannes N. Brønsted (1879–1947) and, independently, the British chemist Thomas M. Lowry (1874–1936) pointed out that acid–base reactions can be seen as proton-transfer reactions and that acids and bases can be defined in terms of this proton ( $\text{H}^+$ ) transfer. According to the Brønsted–Lowry concept, an **acid** is the species donating a proton in a proton-transfer reaction. A **base** is the species accepting the proton in a proton-transfer reaction. ◀

To be precise, we should say *hydrogen nucleus* instead of proton (because natural hydrogen contains some  $^2\text{H}$  as well as  $^1\text{H}$ ). The term proton is conventional in this context, however.

Figure 15.3 ◀

**Representation of the reaction**

Note the transfer of a proton,  $\text{H}^+$ , from  $\text{H}_3\text{O}^+$  to  $\text{NH}_3$ . The charges indicated for ions are *overall* charges. They are not to be associated with specific locations on the ions.

Consider, for example, the reaction of hydrochloric acid with ammonia, which was mentioned in the chapter opening. Writing it as an ionic equation, you have

After canceling  $\text{Cl}^-$ , you obtain the net ionic equation.

In this reaction in aqueous solution, a proton,  $\text{H}^+$ , is transferred from the  $\text{H}_3\text{O}^+$  ion to the  $\text{NH}_3$  molecule, giving  $\text{H}_2\text{O}$  and  $\text{NH}_4^+$  (Figure 15.3). Here  $\text{H}_3\text{O}^+$  is the proton donor, or acid, and  $\text{NH}_3$  is the proton acceptor, or base. Note that in the Brønsted–Lowry concept, acids (and bases) can be ions as well as molecular substances.

You can also apply the Brønsted–Lowry concept to the reaction of  $\text{HCl}$  and  $\text{NH}_3$  dissolved in benzene,  $\text{C}_6\text{H}_6$ , which was mentioned in the chapter opening. In benzene,  $\text{HCl}$  and  $\text{NH}_3$  are not ionized. The equation is

Here the  $\text{HCl}$  molecule is the proton donor, or acid, and the  $\text{NH}_3$  molecule is the proton acceptor, or base.

In any reversible acid–base reaction, both forward and reverse reactions involve proton transfers. Consider the reaction of  $\text{NH}_3$  with  $\text{H}_2\text{O}$ .

In the forward reaction,  $\text{NH}_3$  accepts a proton from  $\text{H}_2\text{O}$ . Thus,  $\text{NH}_3$  is a base and  $\text{H}_2\text{O}$  is an acid. In the reverse reaction,  $\text{NH}_4^+$  donates a proton to  $\text{OH}^-$ .  $\text{NH}_4^+$  ion is the acid and  $\text{OH}^-$  is the base.

Note that  $\text{NH}_3$  and  $\text{NH}_4^+$  differ by a proton. That is,  $\text{NH}_3$  becomes the  $\text{NH}_4^+$  ion by gaining a proton, whereas the  $\text{NH}_4^+$  ion becomes the  $\text{NH}_3$  molecule by losing a proton. The species  $\text{NH}_4^+$  and  $\text{NH}_3$  are a conjugate acid–base pair. A **conjugate acid–base pair** consists of *two species in an acid–base reaction, one acid and one base, that differ by the loss or gain of a proton*. The acid in such a pair is called the *conjugate acid* of the base, whereas the base is the *conjugate base* of the acid. Here  $\text{NH}_4^+$  is the conjugate acid of  $\text{NH}_3$ , and  $\text{NH}_3$  is the conjugate base of  $\text{NH}_4^+$ .

**Example 15.1 Identifying Acid and Base Species****Gaining Mastery Toolbox****Critical Concept 15.1**

A Brønsted–Lowry acid is a proton donor and a Brønsted–Lowry base is a proton acceptor.

**Solution Essentials:**

- Conjugate acid–base pairs
- Acid–base reactions

In the following equations, label each species as an acid or a base. Show the conjugate acid–base pairs.

- $\text{HCO}_3^-(\text{aq}) + \text{HF}(\text{aq}) \rightleftharpoons \text{H}_2\text{CO}_3(\text{aq}) + \text{F}^-(\text{aq})$
- $\text{HCO}_3^-(\text{aq}) + \text{OH}^-(\text{aq}) \rightleftharpoons \text{CO}_3^{2-}(\text{aq}) + \text{H}_2\text{O}(\text{l})$

**Problem Strategy** Recall that a Brønsted–Lowry acid is a proton donor, and the base is a proton acceptor. Examine each equation to find the proton donor on each side. Then label the acids and bases.

(continued)

**Example 15.1** (continued)**Solution**

a. On the left, HF is the proton donor; on the right, H<sub>2</sub>CO<sub>3</sub> is the proton donor. The proton acceptors are HCO<sub>3</sub><sup>-</sup> and F<sup>-</sup>. Once the proton donors and acceptors are identified, the acids and bases can be labeled.

In this reaction, H<sub>2</sub>CO<sub>3</sub> and HCO<sub>3</sub><sup>-</sup> are a conjugate acid–base pair, as are HF and F<sup>-</sup>.

b. You have

Here HCO<sub>3</sub><sup>-</sup> and CO<sub>3</sub><sup>2-</sup> are a conjugate acid–base pair, as are H<sub>2</sub>O and OH<sup>-</sup>. Note that although HCO<sub>3</sub><sup>-</sup> functions as an acid in this reaction, it functions as a base in part a.

**Answer Check** Check that each conjugate acid–base pair consists of one species from the left side of the equation and one species from the right side, and that the two species differ by only a proton.

**Exercise 15.1** For the reaction

label each species as an acid or a base. For the base on the left, what is the conjugate acid?

See Problems 15.35 and 15.36

*Amphoteric* is a general term referring to a species that can act as an acid or a base. The species need not be amphoteric, however. For example, aluminum oxide is an amphoteric oxide, because it reacts with acids and bases. It is not amphoteric, because it has no protons.

The Brønsted–Lowry concept defines a species as an acid or a base according to its function in the acid–base, or proton-transfer, reaction. As you saw in Example 15.1, some species can act as either an acid or a base. An **amphiprotic species** is a species that can act as either an acid or a base (it can lose or gain a proton), depending on the other reactant. ◀ For example, HCO<sub>3</sub><sup>-</sup> acts as an acid in the presence of OH<sup>-</sup> but as a base in the presence of HF. Anions with ionizable hydrogens, such as HCO<sub>3</sub><sup>-</sup>, and certain solvents, such as water, are amphiprotic.

The amphiprotic characteristic of water is important in the acid–base properties of aqueous solutions. Consider, for example, the reactions of water with the base NH<sub>3</sub> and with the acid HC<sub>2</sub>H<sub>3</sub>O<sub>2</sub> (acetic acid).

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCH 02-200-203

In the first case, water reacts as an acid with the base NH<sub>3</sub>. In the second case, water reacts as a base with the acid HC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>.

You have now seen several ways in which the Brønsted–Lowry concept of acids and bases has greater scope than the Arrhenius concept. In the Brønsted–Lowry concept:

1. A base is a species that accepts protons; OH<sup>-</sup> is only one example of a base.
2. Acids and bases can be ions as well as molecular substances.
3. Acid–base reactions are not restricted to aqueous solution.
4. Some species can act as either acids or bases, depending on what the other reactant is.

**CONCEPT CHECK 15.1**

Chemists in the seventeenth century discovered that the substance that gives red ants their irritating bite is an acid with the formula  $\text{HCHO}_2$ . They called this substance formic acid after the ant, whose Latin name is *formica rufus*. Formic acid has the following structural formula and molecular model:

Write the acid–base equilibria connecting all components in the aqueous solution of formic acid. Now list all of the species present.

**15.3 Lewis Concept of Acids and Bases**

Certain reactions have the characteristics of acid–base reactions but do not fit the Brønsted–Lowry concept. An example is the reaction of the basic oxide  $\text{Na}_2\text{O}$  with the acidic oxide  $\text{SO}_3$  to give the salt  $\text{Na}_2\text{SO}_4$ . ▶

Acidic and basic oxides were discussed in Section 8.7.

G. N. Lewis, who proposed the electron-pair theory of covalent bonding, realized that the concept of acids and bases could be generalized to include reactions of acidic and basic oxides and many other reactions, as well as proton-transfer reactions. According to this concept, a **Lewis acid** is a species that can form a covalent bond by accepting an electron pair from another species; a **Lewis base** is a species that can form a covalent bond by donating an electron pair to another species. The Lewis and the Brønsted–Lowry concepts are simply different ways of looking at certain chemical reactions. Such different views are often helpful in understanding reactions.

Consider again the neutralization of  $\text{NH}_3$  by  $\text{HCl}$  in aqueous solution, mentioned earlier. It consists of the reaction of a proton from  $\text{H}_3\text{O}^+$  with  $:\text{NH}_3$ .

Here the red arrow shows the proton accepting an electron pair from  $\text{NH}_3$  and an  $\text{H}-\text{N}$  bond being formed. The proton is an electron-pair acceptor, so it is a Lewis acid. Ammonia,  $\text{NH}_3$ , which has a lone pair of electrons, is an electron-pair donor and therefore a Lewis base.

Now let us look at the reaction of  $\text{Na}_2\text{O}$  with  $\text{SO}_3$ . It involves the reaction of the oxide ion,  $\text{O}^{2-}$ , from the ionic solid,  $\text{Na}_2\text{O}$ , with  $\text{SO}_3$ .

Here  $\text{SO}_3$  accepts the electron pair from the  $\text{O}^{2-}$  ion. At the same time, an electron pair from the  $\text{S}=\text{O}$  bond moves to the O atom. Thus,  $\text{O}^{2-}$  is the Lewis base and  $\text{SO}_3$  is the Lewis acid.

The Lewis concept embraces many reactions that we might not think of as acid–base reactions. The reaction of boron trifluoride with ammonia is an example.

In this reaction, the  $\text{NH}_3$  molecule donates the lone pair of electrons on the nitrogen atom to the boron atom of  $\text{BF}_3$ . Boron trifluoride accepts the electron pair and so is a Lewis acid. Ammonia donates the electron pair and so is a Lewis base. The electron pair originally on the nitrogen atom is now shared between the nitrogen and boron atoms, forming a B–N bond.

The formation of *complex ions* can also be looked at as Lewis acid–base reactions. Complex ions are formed when a metal ion bonds to electron pairs from molecules such as  $\text{H}_2\text{O}$  or  $\text{NH}_3$  or from anions such as  $\text{:C}\equiv\text{N:}^-$ . An example of a complex ion is  $\text{Al}(\text{H}_2\text{O})_6^{3+}$ . Hydrated ions like  $\text{Al}(\text{H}_2\text{O})_6^{3+}$  are present in compounds (hydrates) and in aqueous solution. The formation of a hydrated metal ion, such as  $\text{Al}(\text{H}_2\text{O})_6^{3+}$ , involves a Lewis acid–base reaction.

### Example 15.2 Identifying Lewis Acid and Base Species

#### Gaining Mastery Toolbox

##### Critical Concept 15.2

A Lewis acid is an electron-pair acceptor and a Lewis base is an electron-pair donor.

##### Solution Essentials:

- Complex ions
- Lewis electron-dot formulas

In the following reactions, identify the Lewis acid and the Lewis base.

- $\text{Ag}^+ + 2\text{NH}_3 \rightleftharpoons \text{Ag}(\text{NH}_3)_2^+$
- $\text{B}(\text{OH})_3 + \text{H}_2\text{O} \rightleftharpoons \text{B}(\text{OH})_4^- + \text{H}^+$

**Problem Strategy** Write the equations using Lewis electron-dot formulas. Then identify the electron-pair acceptor, or Lewis acid, and the electron-pair donor, or Lewis base.

#### Solution

- The silver ion,  $\text{Ag}^+$ , forms a complex ion with two  $\text{NH}_3$  molecules.

Life Science

A CHEMIST Looks at ...

# Taking Your Medicine

The expressions “take your medicine” and “a bitter pill to swallow” are metaphors that refer to doing whatever is necessary to solve a difficult personal problem. Taking medicine might be unpleasant if the medicine is bitter—and medicines frequently taste bitter. Why?

A bitter taste appears to be a common feature of a base. It is a fact that many medicinal substances are nitrogen bases, substances that organic chemists call *amines*. Such substances are considered derivatives of ammonia, in which one or more hydrogen atoms have been substituted by carbon-containing groups. Here, for example, are the structures of some amines:

The nitrogen atom in an amine has a lone pair of electrons that can be donated to form a covalent bond, so an amine is a Lewis base. But like ammonia, an amine accepts

a hydrogen ion from an acid to form an amine ion, so it is also a Brønsted–Lowry base:

Some of our most important medicinal drugs have originated from plants. Lewis and Clark took Peruvian bark, or cinchona bark, with them as a medicine on their 1804 expedition from the eastern United States to the Pacific Coast and back. The bitter essence of cinchona bark is quinine, an amine drug that has been used to combat malaria. Quinine is responsible for the bitter taste of tonic water, a carbonated beverage (Figure 15.4). Some other amines that come from plants are caffeine (from coffee, a stimulant), atropine (from the deadly nightshade, used to dilate the pupil of the eye for eye exams), and codeine (from the opium poppy, used as a painkiller).

**Figure 15.4** ▶

**Tonic water** This carbonated beverage contains quinine, which accounts for its bitter taste. Note the N atoms (in blue) in the structural formula of quinine, which give the substance its basic character.

■ See Problems 15.105 and 15.106.

**Example 15.2** (continued)

b. The reaction is

**Answer Check** Check the electron-dot formulas of the species in each acid–base reaction. The Lewis base donates an electron pair to the Lewis acid, which accepts that pair.

**Exercise 15.2** Identify the Lewis acid and the Lewis base in each of the following reactions. Write the chemical equations using electron-dot formulas.

See Problems 15.39, 15.40, 15.41, and 15.42.

## ► Acid and Base Strengths

The Brønsted–Lowry concept considers an acid–base reaction as a proton-transfer reaction. It is useful to consider such acid–base reactions as a competition between species for protons. From this point of view, you can order acids by their relative strengths as proton donors. The stronger acids are those that lose their protons more easily than other acids. Similarly, the stronger bases are those that hold on to protons more strongly than other bases.

### 15.4 Relative Strengths of Acids and Bases

By comparing various acid–base reactions, you can construct a table of relative strengths of acids and bases (see Table 15.2). To see how you might do this, look again at what we have called a strong acid. Recall that an acid is strong if it completely ionizes in water. In the reaction of hydrogen chloride with water, for example, water acts as a base, accepting the proton from HCl.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCH 02-200-203

The reverse reaction occurs only to an extremely small extent. Because the reaction goes almost completely to the right, you say that HCl is a strong acid. However, even though the reaction goes almost completely to products, you can consider the reverse reaction. In it, the  $\text{Cl}^-$  ion acts as the base, accepting a proton from the acid  $\text{H}_3\text{O}^+$ .

Look at this reaction in terms of the relative strengths of the two acids, HCl and  $\text{H}_3\text{O}^+$ . Because HCl is a strong acid, it must lose its proton readily, more readily than  $\text{H}_3\text{O}^+$  does. You would say that HCl is a stronger acid than  $\text{H}_3\text{O}^+$ , or that, of the two,  $\text{H}_3\text{O}^+$  is the weaker acid.

It is important to understand that the terms *stronger* and *weaker* are used here only in a comparative sense. The  $\text{H}_3\text{O}^+$  ion is a relatively strong acid.

**Table 15.2** Relative Strengths of Acids and Bases

	Acid	Base	
Strongest acids ↓ Weakest acids	HClO <sub>4</sub>	ClO <sub>4</sub> <sup>-</sup>	Weakest bases ↑ Strongest bases
	H <sub>2</sub> SO <sub>4</sub>	HSO <sub>4</sub> <sup>-</sup>	
	HI	I <sup>-</sup>	
	HBr	Br <sup>-</sup>	
	HCl	Cl <sup>-</sup>	
	HNO <sub>3</sub>	NO <sub>3</sub> <sup>-</sup>	
	H <sub>3</sub> O <sup>+</sup>	H <sub>2</sub> O	
	HSO <sub>4</sub> <sup>-</sup>	SO <sub>4</sub> <sup>2-</sup>	
	H <sub>2</sub> SO <sub>3</sub>	HSO <sub>3</sub> <sup>-</sup>	
	H <sub>3</sub> PO <sub>4</sub>	H <sub>2</sub> PO <sub>4</sub> <sup>-</sup>	
	HNO <sub>2</sub>	NO <sub>2</sub> <sup>-</sup>	
	HF	F <sup>-</sup>	
	HC <sub>2</sub> H <sub>3</sub> O <sub>2</sub>	C <sub>2</sub> H <sub>3</sub> O <sub>2</sub> <sup>-</sup>	
	Al(H <sub>2</sub> O) <sub>6</sub> <sup>3+</sup>	Al(H <sub>2</sub> O) <sub>5</sub> OH <sup>2+</sup>	
	H <sub>2</sub> CO <sub>3</sub>	HCO <sub>3</sub> <sup>-</sup>	
	H <sub>2</sub> S	HS <sup>-</sup>	
	HClO	ClO <sup>-</sup>	
	HBrO	BrO <sup>-</sup>	
	NH <sub>4</sub> <sup>+</sup>	NH <sub>3</sub>	
	HCN	CN <sup>-</sup>	
HCO <sub>3</sub> <sup>-</sup>	CO <sub>3</sub> <sup>2-</sup>		
H <sub>2</sub> O <sub>2</sub>	HO <sub>2</sub> <sup>-</sup>		
HS <sup>-</sup>	S <sup>2-</sup>		
H <sub>2</sub> O	OH <sup>-</sup>		

An acid–base reaction normally goes in the direction of the weaker acid. You can use this fact to compare the relative strengths of any two acids, as we did in comparing the relative strengths of HCl and H<sub>3</sub>O<sup>+</sup>. As another example, look at the ionization of acetic acid, HC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>, in water.

Experiment reveals that in a 0.1 *M* acetic acid solution, only about 1% of the acetic acid molecules have ionized by this reaction. This implies that HC<sub>2</sub>H<sub>3</sub>O<sub>2</sub> is a weaker acid than H<sub>3</sub>O<sup>+</sup>. If you look at the similar situation for 0.1 *M* HF, you find that about 3% of the HF molecules have dissociated. Thus, HF is a weaker acid than H<sub>3</sub>O<sup>+</sup> but a stronger acid than HC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>. You have already seen that HCl is stronger than H<sub>3</sub>O<sup>+</sup>. Thus, you have determined that the acid strengths for these four acids are in the order HCl > H<sub>3</sub>O<sup>+</sup> > HF > HC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>.

This procedure of determining the relative order of acid strengths by comparing their relative ionizations in water cannot be used to obtain the relative strengths of two strong acids such as HCl and HI. When these acids are dissolved in water, they are essentially 100% ionized. However, if you look at solutions of equal concentrations of these acids in another solvent that is less basic than water—say, pure

acetic acid—you do see a difference. Neither acid is completely ionized, but a greater fraction of HI molecules is found to be ionized. Thus, HI is a stronger acid than HCl. In water, the acid strengths of the strong acids appear to be the same; that is, they are “leveled out.” We say that water exhibits a *leveling effect* on the strengths of the strong acids.

The first column of Table 15.2 lists acids by their strength; the strongest is at the top of the table. Note that the arrow down the left side of the table points toward the weaker acid and is in the direction the reaction goes. For example, in the reaction involving HCl and  $\text{H}_3\text{O}^+$ , the arrow points from HCl toward  $\text{H}_3\text{O}^+$  (the weaker acid) and is in the direction in which the reaction occurs.

You can also view this same reaction in terms of the bases,  $\text{H}_2\text{O}$  and  $\text{Cl}^-$ . A stronger base picks up a proton more readily than does a weaker one. Water has greater base strength than the  $\text{Cl}^-$  ion; that is,  $\text{H}_2\text{O}$  picks up protons more readily than  $\text{Cl}^-$  does. In fact,  $\text{Cl}^-$  has little attraction for protons. (If it had more, HCl would not lose its proton so readily.) Because  $\text{H}_2\text{O}$  molecules compete more successfully for protons than  $\text{Cl}^-$  ions do, the reaction goes almost completely to the right. (Note that the arrow on the right in Table 15.2 points from  $\text{H}_2\text{O}$  to  $\text{Cl}^-$ .) That is, at the completion of the reaction, concentrations of product species ( $\text{Cl}^-$  and  $\text{H}_3\text{O}^+$ ) are much greater than the concentration of reactant HCl.

The reaction goes in the direction of the weaker base.

By comparing reactions between different pairs of bases, you can arrive at a relative order for base strengths, just as for acids. A definite relationship exists between acid and base strengths. When you say an acid loses its proton readily, you can also say that its conjugate base does not hold the proton very tightly. *The strongest acids have the weakest conjugate bases, and the strongest bases have the weakest conjugate acids.* This means that a list of conjugate bases of the acids in Table 15.2 will be in order of increasing base strength. The weakest bases will be at the top of the table and the strongest at the bottom.

You can use Table 15.2 to predict the direction of an acid–base reaction. The direction for an acid–base reaction always favors the weaker acid and weaker base; that is, the normal direction of reaction is from the stronger acid and base to the weaker acid and base. For the reaction we have been discussing, you have

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

The reaction follows the direction of the arrows at the left and right of Table 15.2.

### Example 15.3 Deciding Whether Reactants or Products Are Favored in an Acid–Base Reaction

#### Gaining Mastery Toolbox

##### Critical Concept 15.3

An acid–base reaction goes in the direction of the weaker acid (and weaker base).

##### Solution Essentials:

- Table 15.2 showing relative strengths of acids and bases

For the following reaction, decide which species (reactants or products) are favored at the completion of the reaction.

**Problem Strategy** Use Table 15.2 to compare the relative strengths of acids and bases.

(continued)

**Example 15.3** (continued)

**Solution** If you compare the relative strengths of the two acids  $\text{HCN}$  and  $\text{HSO}_4^-$ , you see that  $\text{HCN}$  is weaker. Or, comparing the bases  $\text{SO}_4^{2-}$  and  $\text{CN}^-$ , you see that  $\text{SO}_4^{2-}$  is weaker. Hence, the reaction would normally go from right to left.

**The reactants are favored.**

**Answer Check** Check that the stronger acid has a weaker conjugate base, and vice versa. The reaction goes from stronger acid and base to weaker acid and base.

**Exercise 15.3** Determine the direction of the following reaction from the relative strengths of acids and bases.

See Problems 15.45, 15.46, 15.47, and 15.48.

**✓ CONCEPT CHECK 15.2**

Formic acid,  $\text{HCHO}_2$ , is a stronger acid than acetic acid,  $\text{HC}_2\text{H}_3\text{O}_2$ . Which is the stronger base, formate ion,  $\text{CHO}_2^-$ , or acetate ion,  $\text{C}_2\text{H}_3\text{O}_2^-$ ?

## 15.5 Molecular Structure and Acid Strength

The strength of an acid depends on how easily the proton,  $\text{H}^+$ , is lost or removed from an  $\text{H}-\text{X}$  bond in the acid species. By understanding the factors that determine the ease of proton loss, you will be able to predict the relative strengths of similar acids.

Two factors are important in determining relative acid strengths. One is the polarity of the bond to which the H atom is attached. The H atom should have a positive partial charge:

The more polarized the bond is in this direction, the more easily the proton is removed and the greater the acid strength.

Figure 15.5 illustrates this idea. It shows *electrostatic-potential maps* of acetic acid,  $\text{HC}_2\text{H}_3\text{O}_2$  or  $\text{CH}_3\text{COOH}$ , and sulfuric acid,  $\text{H}_2\text{SO}_4$ , whose molecular formulas and molecular models are

An electrostatic-potential map shows the electrostatic potential on a surface of fixed electron density. A partial negative potential or polarity ( $\delta^-$ ) is shown in red, and a partial positive polarity ( $\delta^+$ ) is shown in blue, with intermediate values shown from orange to green. Acetic acid has a hydrogen atom attached to an oxygen atom, giving a polar bond, which

**Figure 15.5** ▲

**Electrostatic-potential maps of acetic acid and sulfuric acid molecules** Colors near red represent large negative values of the electrostatic potential, while colors near blue represent large positive values. (Orange, yellow, and green colors represent intermediate values.) Note the hydrogen atoms at the right are colored deep blue, indicating positive potential values, which are indicative of relative acidity of these atoms. Those hydrogen atoms in acetic acid at the top, colored light blue, are not acidic.

Figure 15.5 shows in dark blue, as expected, and this hydrogen atom is acidic. Three hydrogen atoms are attached to a carbon atom (two pointing at the reader, the other below and not visible) and are more negative and are not acidic. The hydrogen atoms in sulfuric acid are dark blue and acidic, as expected.

The second factor determining acid strength is the strength of the bond—that is, how tightly the proton is held. This, in turn, depends on the length of the H—X bond and, therefore, on the size of atom X. The larger atom X, the weaker the bond and the greater the acid strength.

Consider a series of binary acids, HX, formed from a given column of elements of the periodic table. The acids would be compounds of these elements with hydrogen, such as the binary acids of the Group 7A elements: HF, HCl, HBr, and HI. As you go down the column of elements, each time adding a shell of electrons to the atom, the radius increases markedly. For this reason, the size of atom X is the dominant factor in determining the acid strength. *In going down a column of elements of the periodic table, the size of atom X increases, the H—X bond strength decreases, and the strength of the binary acid increases.* You predict the following order of acid strength:

This is the same order shown in Table 15.2.

As you go across a row of elements of the periodic table, the atomic radius decreases slowly. For this reason, the relative strengths of the binary acids of these elements are less dependent on the size of atom X. Now the polarity of the H—X bond becomes the dominant factor in determining acid strength. *Going across a row of elements of the periodic table, the electronegativity increases, the H—X bond polarity increases, and the acid strength increases.* For example, the binary acids of the last two elements of the second period are H<sub>2</sub>O and HF. The acid strengths are

This again is the order shown in Table 15.2. Hydrogen fluoride, HF, is a weak acid, and H<sub>2</sub>O is a very weak acid.

Now consider the oxoacids. An oxoacid has the structure

The acidic H atom is always attached to an O atom, which, in turn, is attached to an atom Y. Other groups, such as O atoms or O—H groups, may also be attached to Y. Bond polarity appears to be the dominant factor determining relative strengths of the oxoacids. This, in turn, depends on the electronegativity of atom Y (see Figure 15.6). If the electronegativity of atom Y is large, the H—O bond is relatively polar and the acid strength large. *For a series of*

**Figure 15.6** ▲

**Effect of atom Y on the acid strengths of acids H—O—Y** Electronegative atoms tend to pull electrons toward themselves. Thus, the O atom in the H—O bond of an oxoacid pulls the bonding electrons toward itself, giving the H atom a positive polarity ( $\delta^+$ ) compared with that of the O atom ( $\delta^-$ ). Other electronegative atoms attached to this O atom increase its effective electronegativity. (The arrow indicates the resulting movement of electrons in each molecule.) Thus, in a series of acids H—O—Y, the acidity increases with the electronegativity of Y. Here H—O—Cl is more acidic than H—O—Br.

Figure 15.7 ◀

**Acid strengths of a series of oxoacids  $(HO)_mYO_n$**  Consider the acids where Y is Cl. The Cl atom becomes effectively more electronegative as more O atoms are attached to it. As a result, the O atom bonded to the H atom becomes effectively more electronegative and so attracts electrons more easily; the H atom then becomes more acidic. Thus,  $HClO_4$  has the greatest acid strength of this series of oxoacids.

oxoacids of the same structure, differing only in the atom Y, the acid strength increases with the electronegativity of Y. Consider, for example, the acids  $HClO$ ,  $HBrO$ , and  $HIO$ . ▶ The structures are

The electronegativity of Group 7A elements decreases going down the column of elements, so the electronegativity decreases from Cl to Br to I. The order of acid strengths is

For a series of oxoacids,  $(HO)_mYO_n$ , the acid strength increases with  $n$ , the number of O atoms bonded to Y (excluding O atoms in OH groups). The oxoacids of chlorine provide an example:

With each additional O atom, the Cl atom becomes effectively more electronegative (see Figure 15.7). As a result, the H atom becomes more acidic. The acid strengths increase in the following order:

Before we leave the subject of molecular structure and acid strength, let us look at the relative acid strengths of a polyprotic acid and its corresponding acid anions. For example,  $H_2SO_4$  ionizes by losing a proton to give  $HSO_4^-$ , which, in turn, ionizes to give  $SO_4^{2-}$ .  $HSO_4^-$  can lose a proton, so it is acidic. However, because of the negative charge of the ion, which tends to attract protons, its acid strength is reduced from that of the uncharged species. That is, the acid strengths are in the order

We conclude that *the acid strength of a polyprotic acid and its anions decreases with increasing negative charge* (see Table 15.2).

**Exercise 15.4** Which member of each of the following pairs is the stronger acid? a.  $NH_3$ ,  $PH_3$ ; b.  $HI$ ,  $H_2Te$ ; c.  $HSO_3^-$ ,  $H_2SO_3$ ; d.  $H_3AsO_4$ ,  $H_3AsO_3$ ; e.  $HSO_4^-$ ,  $HSeO_4^-$

See Problems 15.51 and 15.52.

## ▶ Autoionization of Water and pH

In aqueous solutions, two ions have dominant roles. These ions, the hydronium ion  $H_3O^+$  (or hydrogen ion,  $H^+$ ) and the hydroxide ion  $OH^-$ , are available in any aqueous solution as a result of the *autoionization* of water, a reaction of water with itself, which we will describe in the next section. This will also give us some background to acid–base equilibrium calculations, which we will discuss in Chapter 16.

## 15.6 Autoionization of Water

Although pure water is often considered a nonelectrolyte (nonconductor of electricity), precise measurements do show a very small conduction. This conduction results from **autoionization** (or **self-ionization**), a reaction in which two like molecules react to give ions. In the case of water, a proton from one  $\text{H}_2\text{O}$  molecule is transferred to another  $\text{H}_2\text{O}$  molecule, leaving behind an  $\text{OH}^-$  ion and forming a hydronium ion,  $\text{H}_3\text{O}^+(aq)$ .

You can see the slight extent to which the autoionization of water occurs by noting the small value of its equilibrium constant, which we indicate here as  $K_w$ .

$$K_w = [\text{H}_3\text{O}^+][\text{OH}^-]$$

The concentration of  $\text{H}_2\text{O}$  is excluded here because its concentration remains essentially constant (as an essentially pure liquid,  $\text{H}_2\text{O}$  is excluded from the equilibrium constant; see Section 14.3). We call  $K_w$ , the *equilibrium value of the ion product*  $[\text{H}_3\text{O}^+][\text{OH}^-]$ , the **ion-product constant for water**. At  $25^\circ\text{C}$ , the value of  $K_w$  is  $1.0 \times 10^{-14}$ . Like any equilibrium constant,  $K_w$  varies with temperature. At body temperature ( $37^\circ\text{C}$ ),  $K_w$  equals  $2.5 \times 10^{-14}$ .

$$K_w = [\text{H}_3\text{O}^+][\text{OH}^-] = 1.0 \times 10^{-14} \text{ at } 25^\circ\text{C}$$

Because we often write  $\text{H}^+(aq)$  for  $\text{H}_3\text{O}^+(aq)$ , the ion-product constant for water can be written  $K_w = [\text{H}^+][\text{OH}^-]$ .

Using  $K_w$ , you can calculate the concentrations of  $\text{H}_3\text{O}^+$  and  $\text{OH}^-$  ions in pure water. These ions are produced in equal numbers in pure water, so their concentrations are equal. Let  $x = [\text{H}_3\text{O}^+] = [\text{OH}^-]$ . Then, substituting into the equation for the ion-product constant,

$$K_w = [\text{H}_3\text{O}^+][\text{OH}^-]$$

you get, at  $25^\circ\text{C}$ ,

$$1.0 \times 10^{-14} = x^2$$

Hence,  $x$  equals  $1.0 \times 10^{-7}$ . Thus, the concentrations of  $\text{H}_3\text{O}^+$  and  $\text{OH}^-$  are both  $1.0 \times 10^{-7} M$  in pure water at  $25^\circ\text{C}$ .

If you add an acid or a base to water, the concentrations of  $\text{H}_3\text{O}^+$  and  $\text{OH}^-$  will no longer be equal. The equilibrium-constant equation  $K_w = [\text{H}_3\text{O}^+][\text{OH}^-]$  will still hold, however, as we will discuss in the next section.

## 15.7 Solutions of a Strong Acid or Base

Consider an aqueous solution of a strong acid or base. Suppose you dissolve 0.10 mol HCl in 1.0 L of aqueous solution, giving 0.10 M HCl. You would like to know the concentration of  $\text{H}_3\text{O}^+$  ion in this solution. In addition to the autoionization of water, you have the reaction of HCl with water, which also produces  $\text{H}_3\text{O}^+$  ion. A strong acid such as hydrochloric acid,  $\text{HCl}(aq)$ , essentially reacts completely with water.

Because you started with 0.10 mol HCl in 1.0 L of solution, the reaction will produce 0.10 mol  $\text{H}_3\text{O}^+$ , so the concentration of  $\text{H}_3\text{O}^+$  ion from HCl is 0.10 M.

Now consider the concentration of  $\text{H}_3\text{O}^+$  ion produced by the autoionization of water. In pure water, the concentration of  $\text{H}_3\text{O}^+$  produced is  $1.0 \times 10^{-7} M$ ; in an acid solution, the contribution of  $\text{H}_3\text{O}^+$  from water will be even smaller. You can see this by applying Le Châtelier's principle to the autoionization reaction. When you increase the concentration of  $\text{H}_3\text{O}^+$  in water by adding an acid, the autoionization of water reverses until a new equilibrium is obtained.

Consequently, the concentration of  $\text{H}_3\text{O}^+$  produced by the autoionization of water ( $< 1 \times 10^{-7} M$ ) is negligible in comparison with that produced from  $\text{HCl}$  ( $0.10 M$ ). So,  $0.10 M \text{HCl}$  has a concentration of  $\text{H}_3\text{O}^+$  ion equal to  $0.10 M$ .

In a solution of a strong acid, you can normally ignore the autoionization of water as a source of  $\text{H}_3\text{O}^+$ . The  $\text{H}_3\text{O}^+$  concentration is usually determined by the strong acid concentration. (This is not true when the acid solution is extremely dilute, however. In a solution that is  $1.0 \times 10^{-7} M \text{HCl}$ , the autoionization of water produces an amount of  $\text{H}_3\text{O}^+$  comparable with that produced by  $\text{HCl}$ .)

Although you normally ignore the autoionization of water in calculating the  $\text{H}_3\text{O}^+$  concentration in a solution of a strong acid, the autoionization equilibrium still exists and is responsible for a small concentration of  $\text{OH}^-$  ion. You can use the ion-product constant for water to calculate this concentration. As an example, calculate the concentration of  $\text{OH}^-$  ion in  $0.10 M \text{HCl}$ . You substitute  $[\text{H}_3\text{O}^+] = 0.10 M$  into the equilibrium equation for  $K_w$  (for  $25^\circ\text{C}$ ).

$$K_w = [\text{H}_3\text{O}^+][\text{OH}^-]$$

$$1.0 \times 10^{-14} = 0.10 \times [\text{OH}^-]$$

Solving for  $[\text{OH}^-]$ ,

$$[\text{OH}^-] = \frac{1.0 \times 10^{-14}}{0.10} = 1.0 \times 10^{-13}$$

The  $\text{OH}^-$  concentration is  $1.0 \times 10^{-13} M$ .

Now consider a solution of a strong base, such as  $0.010 M \text{NaOH}$ . What are the  $\text{OH}^-$  and  $\text{H}_3\text{O}^+$  concentrations in this solution? Because  $\text{NaOH}$  is a strong base, all of the  $\text{NaOH}$  is present in the solution as ions. One mole of  $\text{NaOH}$  dissolves in water as one mole of  $\text{Na}^+$  and one mole of  $\text{OH}^-$ . Therefore, the concentration of  $\text{OH}^-$  obtained from  $\text{NaOH}$  in  $0.010 M \text{NaOH}$  solution is  $0.010 M$ . The concentration of  $\text{OH}^-$  produced from the autoionization of water in this solution ( $< 1 \times 10^{-7} M$ ) is negligible and can be ignored. Therefore, the concentration of  $\text{OH}^-$  ion in the solution is  $0.010 M$ . Hydronium ion,  $\text{H}_3\text{O}^+$ , is produced by the autoionization of water. To obtain its concentration, you substitute into the equilibrium equation for  $K_w$  (for  $25^\circ\text{C}$ ).

$$K_w = [\text{H}_3\text{O}^+][\text{OH}^-]$$

$$1.0 \times 10^{-14} = [\text{H}_3\text{O}^+] \times 0.010$$

Solving for  $\text{H}_3\text{O}^+$  concentration,

$$[\text{H}_3\text{O}^+] = \frac{1.0 \times 10^{-14}}{0.010} = 1.0 \times 10^{-12}$$

The  $\text{H}_3\text{O}^+$  concentration is  $1.0 \times 10^{-12} M$ .

The following example further illustrates the calculation of  $\text{H}_3\text{O}^+$  and  $\text{OH}^-$  concentrations in solutions of a strong acid or base.

### Example 15.4 Calculating Concentrations of $\text{H}_3\text{O}^+$ and $\text{OH}^-$ in Solutions of a Strong Acid or Base

#### Gaining Mastery Toolbox

##### Critical Concept 15.4

At equilibrium in water solutions, the ion product  $[\text{H}_3\text{O}^+][\text{OH}^-] = 1.0 \times 10^{-14}$  at  $25^\circ\text{C}$ .

##### Solution Essentials:

- Equilibrium constant involving a pure liquid
- Chemical equilibrium

Calculate the concentrations of hydronium ion and hydroxide ion at  $25^\circ\text{C}$  in:  
a.  $0.15 M \text{HNO}_3$ ,    b.  $0.010 M \text{Ca}(\text{OH})_2$ .

**Problem Strategy** A strong acid (or base) is fully ionized in solution, so you can use its formula and molar concentration to determine the  $\text{H}_3\text{O}^+$  (or  $\text{OH}^-$ ) ion concentration. (If not very dilute, any contribution to this ion concentration from the autoionization of water is negligible.)  $K_w$  relates the  $\text{H}_3\text{O}^+$  and  $\text{OH}^-$  ion concentrations; therefore, you use this relation to obtain the  $\text{OH}^-$  concentration, given the  $\text{H}_3\text{O}^+$  concentration, or vice versa.

(continued)

**Example 15.4** (continued)**Solution**

a. Every mole of  $\text{HNO}_3$  contributes one mole of  $\text{H}_3\text{O}^+$  ion, so the  $\text{H}_3\text{O}^+$  concentration is **0.15 M**. The  $\text{OH}^-$  concentration is obtained from the equation for  $K_w$ .

$$K_w = [\text{H}_3\text{O}^+][\text{OH}^-]$$

$$1.0 \times 10^{-14} = 0.15 \times [\text{OH}^-]$$

so

$$[\text{OH}^-] = \frac{1.0 \times 10^{-14}}{0.15} = 6.7 \times 10^{-14}$$

The concentration of  $\text{OH}^-$  in 0.15 M  $\text{HNO}_3$  is  **$6.7 \times 10^{-14}$  M**.

Every mole of  $\text{Ca}(\text{OH})_2$  that dissolves yields two moles of  $\text{OH}^-$ . Therefore, 0.010 M  $\text{Ca}(\text{OH})_2$  contains  $2 \times 0.010$  M  $\text{OH}^- =$  **0.020 M  $\text{OH}^-$** . The  $\text{H}_3\text{O}^+$  concentration is obtained from

$$K_w = [\text{H}_3\text{O}^+][\text{OH}^-]$$

$$1.0 \times 10^{-14} = [\text{H}_3\text{O}^+] \times 0.020$$

so

$$[\text{H}^+] = \frac{1.0 \times 10^{-14}}{0.020} = 5.0 \times 10^{-13}$$

The hydronium-ion concentration is  **$5.0 \times 10^{-13}$  M**.

**Answer Check** The hydronium-ion concentration of a solution of an acid should be greater than that in pure water ( $1.0 \times 10^{-7}$  M); the hydroxide-ion concentration of a solution of an acid should be less than that in pure water ( $1.0 \times 10^{-7}$  M). The hydroxide-ion concentration of a solution of a base should be greater than that in pure water; the hydronium-ion concentration of a solution of a base should be less than that in pure water. Always check your calculations to see that this is true.

**Exercise 15.5** A solution of barium hydroxide at 25°C is 0.125 M  $\text{Ba}(\text{OH})_2$ . What are the concentrations of hydronium ion and hydroxide ion in the solution?

See Problems 15.53 and 15.54.

By dissolving substances in water, you can alter the concentrations of  $\text{H}_3\text{O}^+$  and  $\text{OH}^-$  ions. In a *neutral* solution, the concentrations of  $\text{H}_3\text{O}^+$  and  $\text{OH}^-$  remain equal, as they are in pure water. In an *acidic* solution, the concentration of  $\text{H}_3\text{O}^+$  is greater than that of  $\text{OH}^-$ . In a *basic* solution, the concentration of  $\text{OH}^-$  is greater than that of  $\text{H}_3\text{O}^+$ . At 25°C, you observe the following conditions:

In an acidic solution,  $[\text{H}_3\text{O}^+] > 1.0 \times 10^{-7}$  M.  
 In a neutral solution,  $[\text{H}_3\text{O}^+] = 1.0 \times 10^{-7}$  M.  
 In a basic solution,  $[\text{H}_3\text{O}^+] < 1.0 \times 10^{-7}$  M

**Exercise 15.6** A solution has a hydroxide-ion concentration of  $1.0 \times 10^{-5}$  M at 25°C. Is the solution acidic, neutral, or basic?

See Problems 15.59 and 15.60.

**CONCEPT CHECK 15.3**

Rank the following solutions from most acidic to most basic (water molecules have been omitted for clarity).

**15.8 The pH of a Solution**

You see that whether an aqueous solution is acidic, neutral, or basic depends on the hydronium-ion concentration. You can quantitatively describe the acidity by giving the hydronium-ion concentration. But because these concentration values may be very small, it is often more convenient to give the acidity in terms of **pH**, which is defined as *the negative of the base 10 logarithm of the molar hydronium-ion concentration*: ▶

$$\text{pH} = -\log [\text{H}_3\text{O}^+]$$

(You can also write  $\text{pH} = -\log [\text{H}^+]$ .) For a solution in which the hydronium-ion concentration is  $1.0 \times 10^{-3} \text{ M}$ , the pH is

$$\text{pH} = -\log(1.0 \times 10^{-3}) = 3.00$$

Note that the number of places after the decimal point in the pH equals the number of significant figures reported in the hydronium-ion concentration. ▶

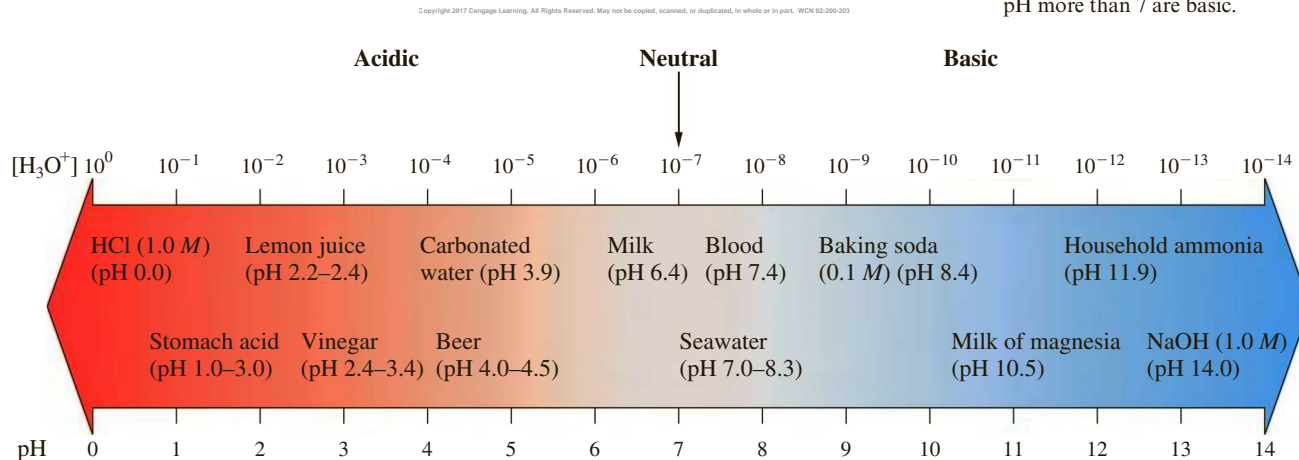

A neutral solution, whose hydronium-ion concentration at 25°C is  $1.0 \times 10^{-7} \text{ M}$ , has a pH of 7.00. For an acidic solution, the hydronium-ion concentration is greater than  $1.0 \times 10^{-7} \text{ M}$ , so the pH is less than 7.00. Similarly, a basic solution has a pH greater than 7.00. Figure 15.8 shows a diagram of the pH scale and lists pH values of some common solutions.

The Danish biochemist S. P. L. Sørensen devised the pH scale while working on the brewing of beer.

See Appendix A for a discussion of logarithms.

**Figure 15.8** ▼

**The pH scale** Solutions having pH less than 7 are acidic; those having pH more than 7 are basic.

**Example 15.5** Calculating the pH from the Hydronium-Ion Concentration**Gaining Mastery Toolbox****Critical Concept 15.5**

The pH of a solution equals  $-\log [\text{H}^+]$ .

**Solution Essentials:**

- $K_w = [\text{H}_3\text{O}^+][\text{OH}^-] = 1.0 \times 10^{-14}$  at 25°C
- Molar concentration

A sample of orange juice has a hydronium-ion concentration of  $2.9 \times 10^{-4} M$ . What is the pH? Is the solution acidic?

**Problem Strategy** pH is the negative base 10 logarithm of the molar hydronium-ion concentration. Determine the log using an electronic calculator; instructions vary, so refer to those for your calculator. On many calculators, you enter the  $\text{H}_3\text{O}^+$  concentration, press *log*, and change the sign of the result. You should write the pH with the same number of decimal places as there are significant figures in  $[\text{H}_3\text{O}^+]$ .

**Solution**

$$\text{pH} = -\log [\text{H}_3\text{O}^+] = -\log(2.9 \times 10^{-4}) = \mathbf{3.54}$$

The pH is less than 7.00, so the solution is **acidic** (as you expect for orange juice).

**Answer Check** Having obtained the pH, you should check the result by calculating  $10^{-\text{pH}}$ , which should give you back the hydronium-ion concentration of the solution. Remember that a pH greater than 7 is basic and a pH less than 7 is acidic.

**Exercise 15.7** What is the pH of a sample of gastric juice (digestive juice in the stomach) whose hydronium-ion concentration is 0.045 M?

See Problems 15.67 and 15.68.

You can find the pH of a solution of known hydroxide-ion concentration by first solving for the hydronium-ion concentration, as shown in Example 15.4b. However, you can also find the pH simply from the pOH, a measure of hydroxide-ion concentration similar to the pH:

$$\text{pOH} = -\log[\text{OH}^-]$$

Then, because  $K_w = [\text{H}_3\text{O}^+][\text{OH}^-] = 1.0 \times 10^{-14}$  at 25°C, you can show that ◀

$$\text{pH} + \text{pOH} = 14.00$$

You can rearrange this equation to obtain the pH from the value of pOH. For example, suppose you wish to find the pH of an ammonia solution whose hydroxide-ion concentration is  $1.9 \times 10^{-3} M$ . You first calculate the pOH.

$$\text{pOH} = -\log(1.9 \times 10^{-3}) = 2.72$$

Then the pH is

$$\begin{aligned} \text{pH} &= 14.00 - \text{pOH} \\ &= 14.00 - 2.72 = 11.28 \end{aligned}$$

Taking the logarithm of both sides of the equation

$$[\text{H}_3\text{O}^+][\text{OH}^-] = 1.0 \times 10^{-14}$$

you get

$$\log [\text{H}_3\text{O}^+] + \log [\text{OH}^-] = -14.00$$

or

$$(-\log [\text{H}_3\text{O}^+]) + (-\log [\text{OH}^-]) = 14.00$$

Hence,  $\text{pH} + \text{pOH} = 14.00$ .

**Exercise 15.8** A saturated solution of calcium hydroxide has a hydroxide-ion concentration of 0.025 M. What is the pH of the solution?

See Problems 15.73 and 15.74.

The usefulness of the pH scale depends on the ease with which you can interconvert pH and hydronium-ion concentrations. In the next example, you will find the hydronium-ion concentration, given the pH value.

**Example 15.6** Calculating the Hydronium-Ion Concentration from the pH**Gaining Mastery Toolbox****Critical Concept 15.6**

You can obtain the hydronium-ion concentration from pH:  $[\text{H}_3\text{O}^+] = 10^{-\text{pH}}$

**Solution Essentials:**

- $K_w = [\text{H}_3\text{O}^+][\text{OH}^-] = 1.0 \times 10^{-14}$  at 25°C
- Molar concentration

The pH of human arterial blood is 7.40. What is the hydronium-ion concentration?

**Problem Strategy** The hydronium-ion concentration is

$$[\text{H}_3\text{O}^+] = \text{antilog}(-\text{pH}) = 10^{-\text{pH}}$$

On some calculators, you obtain the antilogarithm by taking the *inverse* of the logarithm. On others, you use a  $10^x$  key.

**Solution** The result is

$$[\text{H}_3\text{O}^+] = \text{antilog}(-7.40) = 10^{-7.40} = \mathbf{4.0 \times 10^{-8} M}$$

Because the pH was given to two decimal places, you write the hydronium-ion concentration with two significant figures.

**Answer Check** Check your result by using your answer (the hydronium-ion concentration) to obtain the pH ( $= -\log [\text{H}_3\text{O}^+]$ ).

**Exercise 15.9** A brand of carbonated beverage has a pH of 3.16. What is the hydronium-ion concentration of the beverage?

See Problems 15.75 and 15.76.

**Exercise 15.10** A 0.010 M solution of ammonia,  $\text{NH}_3$ , has a pH of 10.6 at 25°C. What is the concentration of hydroxide ion? (One way to solve this problem is to find the pOH first and then calculate the hydroxide-ion concentration.)

See Problems 15.77 and 15.78.

The pH of a solution can be accurately measured by a pH meter (Figure 15.9). This instrument consists of specially designed electrodes that are dipped into the solution. A voltage, which depends on the pH, is generated between the electrodes and is read on a meter calibrated directly in pH. (The principle behind the operation of a pH meter is discussed in Chapter 19.)

Although less precise, acid–base indicators are often used to measure pH, because they usually change color within a small pH range. The color change of an indicator involves establishment of an equilibrium between an acid form and a base form that have different colors. If we denote the acid form as  $\text{HIn}$ , then the base form is  $\text{In}^-$  and the equilibrium is

Consider the case of phenolphthalein. The acid form is colorless and the base form is pink. When a base is added to an acidic solution of phenolphthalein,  $\text{OH}^-$  ion from the base reacts with  $\text{H}_3\text{O}^+$  in the solution. According to Le Châtelier's principle, the equilibrium is shifted to the right (to replenish  $\text{H}_3\text{O}^+$ ). Thus, the colorless acid form of the indicator,  $\text{HIn}$ , is converted to the pink base form,  $\text{In}^-$ . A solution of phenolphthalein begins to turn pink at about pH 8.0. By pH 9.7, the color change is essentially complete. ▶ Figure 15.10 shows the color changes for various acid–base indicators. (See also Figure 15.11.) Paper strips impregnated with several indicators are often used to measure pH values. Such “pH paper” gives a definite color for different pH ranges and can give the pH to the nearest integer value or better.

**Figure 15.9** ▲

**A digital pH meter** The experimenter places a probe containing electrodes into the solution and reads the pH on the meter.

Litmus contains several substances and changes color over a broader range, from about pH 5 to pH 8.

Figure 15.10 ▲

**Color changes of some acid–base indicators** Acid–base indicators are dyes whose acid form has one color and whose base form has another color. Thymol blue is a diprotic acid and has two different color changes (listed here in the acidic range and the basic range).

✓ **CONCEPT CHECK 15.4**

You have solutions of  $\text{NH}_3$ ,  $\text{HCl}$ ,  $\text{NaOH}$ , and  $\text{HC}_2\text{H}_3\text{O}_2$  (acetic acid), all with the same solute concentrations. Rank these solutions in order of pH, from the highest to the lowest.

Figure 15.11 ▲

**Some acid–base indicators in solutions of different  $\text{H}_3\text{O}^+$  concentrations.** Universal indicator is a mixture of acid–base indicators.

## Daily Life

A CHEMIST Looks at . . .

# Unclogging the Sink and Other Chores

When the sink drain is clogged, you might need a strong arm, but a strong base might work just as well. Drain cleaner solutions, available in grocery stores, are simply solutions of sodium hydroxide, a strong base. Such solutions work by chemically reacting with fat and with hair, the usual ingredients of a stopped drain. When fat reacts with a strong base such as sodium hydroxide, it forms the salt of a fatty acid, a product otherwise known as soap. Hair is a protein material, and in the presence of a strong base, the protein breaks up into the salts of its constituent amino acids. So a wad of greasy hair packed in a drain, in the presence of sodium hydroxide, becomes a soapy solution of amino acid salts. That solution washes easily down the drain. Oven cleaner is a paste made of sodium hydroxide. It cleans by reacting with the fatty deposits and other residues in the oven.

Sodium hydroxide is produced commercially by sending a direct current through an aqueous solution of sodium chloride, a process referred to as electrolysis (Figure 15.12). Hydrogen gas is released at the negative pole and chlorine gas is released at the positive pole. At the end of the electrolysis, the solution contains sodium hydroxide. The overall reaction is

Chlorine is prepared commercially in this same process.

Figure 15.12 ▲

**Preparation of sodium hydroxide by hydrolysis** A solution of sodium chloride is electrolyzed. Note the pink color at the negative electrode. The phenolphthalein indicator turns pink from the hydroxide ion formed at the electrode. Later, if we evaporate the solution, sodium hydroxide crystallizes out.

■ See Problems 15.107 and 15.108.

## ✓ A Checklist for Review

### Summary of Facts and Concepts

The *Arrhenius concept* was the first successful theory of acids and bases. Then, in 1923, Brønsted and Lowry characterized acid–base reactions as proton-transfer reactions. According to the *Brønsted–Lowry concept*, an acid is a proton donor and a base is a proton acceptor. The *Lewis concept* is even more general than the Brønsted–Lowry concept. A Lewis acid is an electron-pair acceptor and a Lewis base is an electron-pair donor. Reactions of acidic and basic oxides and the formation of complex ions, as well as proton-transfer reactions, can be described in terms of the Lewis concept. Acid–base reactions can be viewed as a competition for protons. Using this idea, you can construct a table of *relative strengths of acids and bases*. Reaction favors the weaker acid

and the weaker base. Acid strength depends on the polarity and the strength of the bond involving the acidic hydrogen atom. Therefore, you can *relate molecular structure and acid strength*. The text gives a number of rules that allow you to predict the relative strengths of similar acids based on molecular structure.

Water ionizes to give hydronium ion and hydroxide ion. The concentrations of these ions in aqueous solution are related by the *ion-product constant for water* ( $K_w$ ). Thus, you can describe the acidity or basicity of a solution by the hydronium-ion concentration. You often use the *pH*, which is the negative base 10 logarithm of the hydronium-ion concentration, as a measure of acidity.

## Questions and Problems

### Self-Assessment and Review Questions

**Key:** These questions test your understanding of the ideas you worked with in the chapter. These problems vary in difficulty and often can be used for the basis of discussion.

**15.1** Which of the following are strong acids? Which are weak acids? **a**  $\text{HC}_2\text{H}_3\text{O}_2$ ; **b**  $\text{HClO}$ ; **c**  $\text{HCl}$ ; **d**  $\text{HNO}_3$ ; **e**  $\text{HNO}_2$ ; **f**  $\text{HCN}$

**15.2** Describe any thermochemical (heat of reaction) evidence for the Arrhenius concept.

**15.3** Define an acid and a base according to the Brønsted–Lowry concept. Give an acid–base equation and identify each species as an acid or a base.

**15.4** What is meant by the conjugate acid of a base?

**15.5** Write an equation in which  $\text{H}_2\text{PO}_3^-$  acts as an acid and another in which it acts as a base.

**15.6** Describe four ways in which the Brønsted–Lowry concept expands on the Arrhenius concept.

**15.7** Define an acid and a base according to the Lewis concept. Give a chemical equation to illustrate.

**15.8** Explain why an acid–base reaction favors the weaker acid.

**15.9** Give two important factors that determine the strength of an acid. How does an increase in each factor affect the acid strength?

**15.10** What is meant by the autoionization of water? Write the expression for  $K_w$ . What is its value at  $25^\circ\text{C}$ ?

**15.11** What is meant by the pH of a solution? Describe two ways of measuring pH.

**15.12** Which is more acidic, a solution having a pH of 4 or one having a pH of 5?

**15.13** What is the pH of a neutral solution at  $37^\circ\text{C}$ , where  $K_w$  equals  $2.5 \times 10^{-14}$ ?

**15.14** What is the sum of the pH and the pOH for a solution at  $37^\circ\text{C}$ , where  $K_w$  equals  $2.5 \times 10^{-14}$ ?

**15.15** The conjugate base of hydrofluoric acid dissolved in water is:

- |                                 |                        |
|---------------------------------|------------------------|
| <b>a</b> $\text{F}^-$           | <b>b</b> $\text{OH}^-$ |
| <b>c</b> $\text{H}_3\text{O}^+$ | <b>d</b> $\text{HF}$   |
| <b>e</b> $\text{F}_2$           |                        |

**15.16** In the following reaction, identify the Lewis acid.

- |                        |  |
|------------------------|--|
| <b>a</b> $\text{CN}^-$ | <b>b</b> $\text{Fe}(\text{CN})_6^{3-}$ |
| <b>c</b> $\text{H}^+$  | <b>d</b> $\text{Fe}^{3+}$              |
| <b>e</b> $\text{OH}^-$ |  |

**15.17** Calculate the hydronium-ion concentration at  $25^\circ\text{C}$  in a  $1.3 \times 10^{-2} \text{ M}$   $\text{Ba}(\text{OH})_2$  solution.

- |   |  |
|---|--|
| <b>a</b> $1.3 \times 10^{-2} \text{ M}$ | <b>b</b> $7.7 \times 10^{-13} \text{ M}$ |
| <b>c</b> $2.6 \times 10^{-2} \text{ M}$ | <b>d</b> $3.8 \times 10^{-13} \text{ M}$ |
| <b>e</b> $1.5 \times 10^2 \text{ M}$    |  |

**15.18** The pH of a solution is 9.55 at  $25^\circ\text{C}$ . What is the hydroxide-ion concentration in the solution?

- |  |   |
|--|---|
| <b>a</b> $2.8 \times 10^{-10} \text{ M}$ | <b>b</b> $3.5 \times 10^{-5} \text{ M}$ |
| <b>c</b> $3.1 \times 10^{-10} \text{ M}$ | <b>d</b> $3.2 \times 10^{-5} \text{ M}$ |
| <b>e</b> $3.8 \times 10^{-5} \text{ M}$  |   |

### Concept Explorations

**Key:** Concept explorations are comprehensive problems that provide a framework that will enable you to explore and learn many of the critical concepts and ideas in each chapter. If you master the concepts associated with these explorations, you will have a better understanding of many important chemistry ideas and will be more successful in solving all types of chemistry problems. These problems are well suited for group work and for use as in-class activities.

#### 15.19 Acids

You make a solution by dissolving 0.0010 mol of  $\text{HCl}$  in enough water to make 1.0 L of solution.

- Write the chemical equation for the reaction of  $\text{HCl}(\text{aq})$  and water.
- Without performing calculations, give a rough estimate of the pH of the  $\text{HCl}$  solution. Justify your answer.
- Calculate the  $\text{H}_3\text{O}^+$  concentration and the pH of the solution.
- Is there any concentration of the base  $\text{OH}^-$  present in this solution of  $\text{HCl}(\text{aq})$ ? If so, where did it come from?
- If you increase the  $\text{OH}^-$  concentration of the solution by adding  $\text{NaOH}$ , does the  $\text{H}_3\text{O}^+$  concentration change? If you think it does, explain why this change occurs and whether the  $\text{H}_3\text{O}^+$  concentration increases or decreases.

- If you were to measure the pH of 10 drops of the original  $\text{HCl}$  solution, would you expect it to be different from the pH of the entire sample? Explain.
- Explain how two different volumes of your original  $\text{HCl}$  solution can have the same pH yet contain different moles of  $\text{H}_3\text{O}^+$ .
- If 1.0 L of pure water were added to the  $\text{HCl}$  solution, would this have any impact on the pH? Explain.

#### 15.20 Strong Acids, Weak Acids, and pH

Two 0.10-mol samples of the hypothetical monoprotic acids  $\text{HA}(\text{aq})$  and  $\text{HB}(\text{aq})$  are used to prepare 1.0-L stock solutions of each acid.

- Write the chemical reactions for these acids in water. What are the concentrations of the two acid solutions?
- One of these acids is a strong acid, and one is weak. What could you measure that would tell you which acid was strong and which was weak?
- Say that the  $\text{HA}(\text{aq})$  solution has a pH of 3.7. Is this the stronger of the two acids? How did you arrive at your answer?
- What is the concentration of  $\text{A}^-(\text{aq})$  in the  $\text{HA}$  solution described in part c?
- If  $\text{HB}(\text{aq})$  is a strong acid, what is the hydronium-ion concentration?

- f** In the solution of  $\text{HB}(aq)$ , which of the following would you expect to be in the greatest concentration:  $\text{H}_3\text{O}^+(aq)$ ,  $\text{B}^-(aq)$ ,  $\text{HB}(aq)$ , or  $\text{OH}^-(aq)$ ? How did you decide?
- g** In the solution of  $\text{HA}(aq)$ , which of the following would you expect to be in the greatest concentration:  $\text{H}_3\text{O}^+(aq)$ ,  $\text{A}^-(aq)$ ,  $\text{HA}(aq)$ , or  $\text{OH}^-(aq)$ ? How did you decide?

- h** Say you add 1.0 L of pure water to a solution of  $\text{HB}$ . Would this water addition make the solution more acidic, make it less acidic, or not change the acidity of the original solution? Be sure to fully justify your answer.
- i** You prepare a 1.0-L solution of  $\text{HA}$ . You then take a 200-mL sample of this solution and place it into a separate container. Would this 200 mL sample be more acidic, be less acidic, or have the same acidity as the original 1.0-L solution of  $\text{HA}(aq)$ ? Be sure to support your answer.

## Conceptual Problems

**Key:** These problems are designed to check your understanding of the concepts associated with some of the main topics presented in each chapter. A strong conceptual understanding of chemistry is the foundation for both applying chemical knowledge and solving chemical problems. These problems vary in level of difficulty and often can be used as a basis for group discussion.

**15.21** Aqueous solutions of ammonia,  $\text{NH}_3$ , were once thought to be solutions of an ionic compound (ammonium hydroxide,  $\text{NH}_4\text{OH}$ ) in order to explain how the solutions could contain hydroxide ion. Using the Brønsted–Lowry concept, show how  $\text{NH}_3$  yields hydroxide ion in aqueous solution without involving the species  $\text{NH}_4\text{OH}$ .

**15.22** Blood contains several substances that minimize changes in its acidity by reacting with either an acid or a base. One of these is the hydrogen phosphate ion,  $\text{HPO}_4^{2-}$ . Write one equation showing this species acting as a Brønsted–Lowry acid and another in which the species acts as a Brønsted–Lowry base.

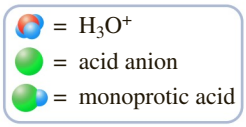

**15.23** Self-contained environments, such as that of a space station, require that the carbon dioxide exhaled by people be continuously removed. This can be done by passing the air over solid alkali hydroxide, in which carbon dioxide reacts with hydroxide ion. What ion is produced by the addition of  $\text{OH}^-$  ion to  $\text{CO}_2$ ? Use the Lewis concept to explain this.

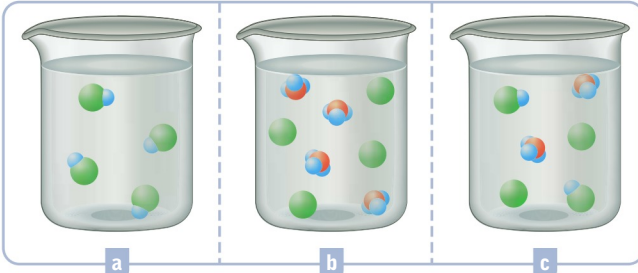

**15.24** Compare the structures of  $\text{HNO}_2$  and  $\text{H}_2\text{CO}_3$ . Which would you expect to be the stronger acid? Explain your choice.

**15.25** The value of the ion-product constant for water,  $K_w$ , increases with temperature. What will be the effect of increasing the temperature on the pH of pure water?

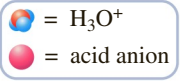

**15.26** You make solutions of ammonia and sodium hydroxide by adding the same moles of each solute to equal volumes of water. Which solution would you expect to have the higher pH?

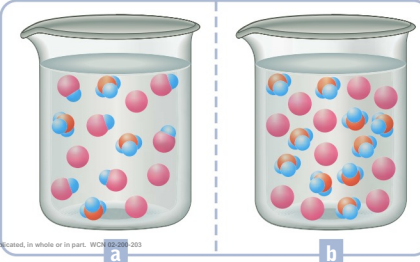

**15.27** A strong monoprotic acid, with the molecular structure , is dissolved in a beaker of water. Which of the following pictures best represents the acid solution (water molecules have been omitted for clarity)?

**15.28** A weak acid,  $\text{HA}$ , is dissolved in water. Which one of the following beakers represents the resulting solution? (Water molecules have been omitted for clarity.)

## Practice Problems

**Key:** These problems are for practice in applying problem-solving skills. They are divided by topic, and some are keyed to exercises (see the ends of the exercises). The problems are arranged in matching pairs; the odd-numbered problem of each pair is listed first, and its answer is given in the back of the book.

### Brønsted–Lowry Concept

**15.29** Write the balanced reaction of hydroxide ion with hydrofluoric acid,  $\text{HF}$ , to form fluoride ion and water. Identify each species as either an acid or a base.

**15.30** Write the balanced reaction of hypobromous acid,  $\text{HOBr}$ , with water to form hydronium ion and the conjugate base of  $\text{HOBr}$ . Identify each species as either an acid or a base.

**15.31** Give the conjugate base to each of the following species regarded as acids.

- |                              |                                     |
|------------------------------|-------------------------------------|
| <b>a</b> $\text{HPO}_4^{2-}$ | <b>b</b> $\text{H}_2\text{S}$       |
| <b>c</b> $\text{HNO}_2$      | <b>d</b> $\text{H}_2\text{AsO}_4^-$ |

**15.32** Give the conjugate base to each of the following species regarded as acids:

- |                           |                          |
|---------------------------|--------------------------|
| <b>a</b> $\text{HSO}_4^-$ | <b>b</b> $\text{PH}_4^+$ |
| <b>c</b> $\text{HSe}^-$   | <b>d</b> $\text{HOBr}$   |

**15.33** Give the conjugate acid to each of the following species regarded as bases.

- a**  $\text{ClO}^-$                                    **b**  $\text{AsH}_3$   
**c**  $\text{H}_2\text{PO}_4^-$                                **d**  $\text{TeO}_3^{2-}$

**15.34** Give the conjugate acid to each of the following species regarded as bases.

- a**  $\text{HS}^-$                                        **b**  $\text{NH}_2^-$   
**c**  $\text{BrO}_2^-$                                    **d**  $\text{N}_2\text{H}_4$

**15.35** For the following reactions, label each species as an acid or a base. Indicate the species that are conjugates of one another.

- a**  $\text{HSO}_4^- + \text{NH}_3 \rightleftharpoons \text{SO}_4^{2-} + \text{NH}_4^+$   
**b**  $\text{HPO}_4^{2-} + \text{NH}_4^+ \rightleftharpoons \text{H}_2\text{PO}_4^- + \text{NH}_3$   
**c**  $\text{Al}(\text{H}_2\text{O})_6^{3+} + \text{H}_2\text{O} \rightleftharpoons \text{Al}(\text{H}_2\text{O})_5\text{OH}^{2+} + \text{H}_3\text{O}^+$   
**d**  $\text{SO}_3^{2-} + \text{NH}_4^+ \rightleftharpoons \text{HSO}_3^- + \text{NH}_3$

**15.36** For the following reactions, label each species as an acid or a base. Indicate the species that are conjugates of one another.

- a**  $\text{H}_2\text{PO}_4^- + \text{HCO}_3^- \rightleftharpoons \text{HPO}_4^{2-} + \text{H}_2\text{CO}_3$   
**b**  $\text{F}^- + \text{HSO}_4^- \rightleftharpoons \text{HF} + \text{SO}_4^{2-}$   
**c**  $\text{HSO}_4^- + \text{H}_2\text{O} \rightleftharpoons \text{SO}_4^{2-} + \text{H}_3\text{O}^+$   
**d**  $\text{H}_2\text{S} + \text{CN}^- \rightleftharpoons \text{HS}^- + \text{HCN}$

### Lewis Acid–Base Concept

**15.37** The following shows ball-and-stick models of the reactants in a Lewis acid–base reaction.

Write the complete equation for the reaction, including the product. Identify each reactant as a Lewis acid or a Lewis base.

**15.38** The following shows ball-and-stick models of the reactants in a Lewis acid–base reaction.

Write the complete equation for the reaction, including the product. Identify each reactant as a Lewis acid or a Lewis base.

**15.39** Complete each of the following equations. Then write the Lewis formulas of the reactants and products and identify each reactant as a Lewis acid or a Lewis base.

- a**  $\text{AlCl}_3 + \text{Cl}^- \longrightarrow$   
**b**  $\text{I}^- + \text{I}_2 \longrightarrow$

**15.40** Complete each of the following equations. Then write the Lewis formulas of the reactants and products and identify each reactant as a Lewis acid or a Lewis base.

- a**  $\text{InCl}_3 + \text{Cl}^- \longrightarrow$   
**b**  $\text{BBr}_3 + \text{Br}^- \longrightarrow$

**15.41** In the following reactions, identify each reactant as a Lewis acid or a Lewis base.

- a**  $\text{Cu}^{2+} + 6\text{H}_2\text{O} \longrightarrow \text{Cu}(\text{H}_2\text{O})_6^{2+}$   
**b**  $\text{BBr}_3 + \text{:AsH}_3 \longrightarrow \text{Br}_3\text{B:AsH}_3$

**15.42** In the following reactions, label each reactant as a Lewis acid or a Lewis base.

- a**  $\text{BeF}_2 + 2\text{F}^- \longrightarrow \text{BeF}_4^{2-}$   
**b**  $\text{Ag}^+ + 2\text{CN}^- \longrightarrow \text{Ag}(\text{CN})_2^-$

**15.43** Natural gas frequently contains hydrogen sulfide,  $\text{H}_2\text{S}$ .  $\text{H}_2\text{S}$  is removed from natural gas by passing it through aqueous ethanamine,  $\text{HOCH}_2\text{CH}_2\text{NH}_2$  (an ammonia derivative), which reacts with the hydrogen sulfide. Write the equation for the reaction. Identify each reactant as either a Lewis acid or a Lewis base. Explain how you arrived at your answer.

**15.44** Coal and other fossil fuels usually contain sulfur compounds that produce sulfur dioxide,  $\text{SO}_2$ , when burned. One possible way to remove the sulfur dioxide is to pass the combustion gases into a tower packed with calcium oxide,  $\text{CaO}$ . Write the equation for the reaction. Identify each reactant as either a Lewis acid or a Lewis base. Explain how you arrived at your answer.

### Acid and Base Strengths

**15.45** Complete the following equation. Using Table 15.2, predict whether you would expect the reaction to occur to any significant extent or whether the reaction is more likely to occur in the opposite direction.

**15.46** Complete the following equation. Using Table 15.2, predict whether you would expect the reaction to occur to any significant extent or whether the reaction is more likely to occur in the opposite direction.

**15.47** Use Table 15.2 to decide whether the species on the left or those on the right are favored by the reaction.

- a**  $\text{NH}_4^+ + \text{H}_2\text{PO}_4^- \rightleftharpoons \text{NH}_3 + \text{H}_3\text{PO}_4$   
**b**  $\text{HCN} + \text{HS}^- \rightleftharpoons \text{CN}^- + \text{H}_2\text{S}$   
**c**  $\text{HCO}_3^- + \text{OH}^- \rightleftharpoons \text{CO}_3^{2-} + \text{H}_2\text{O}$   
**d**  $\text{Al}(\text{H}_2\text{O})_6^{3+} + \text{OH}^- \rightleftharpoons \text{Al}(\text{H}_2\text{O})_5\text{OH}^{2+} + \text{H}_2\text{O}$

**15.48** Use Table 15.2 to decide whether the species on the left or those on the right are favored by the reaction.

- a**  $\text{NH}_4^+ + \text{CO}_3^{2-} \rightleftharpoons \text{NH}_3 + \text{HCO}_3^-$   
**b**  $\text{HCO}_3^- + \text{H}_2\text{S} \rightleftharpoons \text{H}_2\text{CO}_3 + \text{HS}^-$   
**c**  $\text{CN}^- + \text{H}_2\text{O} \rightleftharpoons \text{HCN} + \text{OH}^-$   
**d**  $\text{CN}^- + \text{H}_2\text{CO}_3 \rightleftharpoons \text{HCN} + \text{HCO}_3^-$

**15.49** In the following reaction of trichloroacetic acid,  $\text{HC}_2\text{Cl}_3\text{O}_2$ , with formate ion,  $\text{CHO}_2^-$ , the formation of trichloroacetate ion,  $\text{C}_2\text{Cl}_3\text{O}_2^-$ , and formic acid,  $\text{HCHO}_2$  is favored.

Which is the stronger acid, trichloroacetic acid or formic acid? Explain.

**15.50** In the following reaction of tetrafluoroboric acid,  $\text{HBF}_4$ , with the acetate ion,  $\text{C}_2\text{H}_3\text{O}_2^-$ , the formation of tetrafluoroborate ion,  $\text{BF}_4^-$ , and acetic acid,  $\text{HC}_2\text{H}_3\text{O}_2$  is favored.

Which is the weaker base,  $\text{BF}_4^-$  or acetate ion?

**15.51** For each of the following pairs, give the stronger acid. Explain your answer.

- a**  $\text{H}_2\text{S}$ ,  $\text{HS}^-$                       **b**  $\text{H}_2\text{SO}_3$ ,  $\text{H}_2\text{SeO}_3$   
**c**  $\text{HBr}$ ,  $\text{H}_2\text{Se}$                       **d**  $\text{HIO}_4$ ,  $\text{HIO}_3$   
**e**  $\text{H}_2\text{S}$ ,  $\text{H}_2\text{O}$

**15.52** Order each of the following pairs by acid strength, giving the weaker acid first. Explain your answer.

- a**  $\text{HNO}_3$ ,  $\text{HNO}_2$                       **b**  $\text{HCO}_3^-$ ,  $\text{H}_2\text{CO}_3$   
**c**  $\text{H}_2\text{S}$ ,  $\text{H}_2\text{Te}$                       **d**  $\text{HCl}$ ,  $\text{H}_2\text{S}$   
**e**  $\text{H}_3\text{PO}_4$ ,  $\text{H}_3\text{AsO}_4$

### Solutions of a Strong Acid or Base

**15.53** What are the concentrations of  $\text{H}_3\text{O}^+$  and  $\text{OH}^-$  in each of the following?

- a** 1.2 M  $\text{HBr}$                               **b** 0.32 M  $\text{KOH}$   
**c** 0.085 M  $\text{Ca}(\text{OH})_2$                       **d** 0.38 M  $\text{HNO}_3$

**15.54** What are the concentrations of  $\text{H}_3\text{O}^+$  and  $\text{OH}^-$  in each of the following?

- a** 1.55 M  $\text{NaOH}$                               **b** 0.15 M  $\text{Sr}(\text{OH})_2$   
**c** 0.056 M  $\text{HClO}_4$                               **d** 0.47 M  $\text{HCl}$

**15.55** A solution of hydrochloric acid is 0.059 M  $\text{HCl}$ . What is the hydronium-ion concentration at 25°C? What is the hydroxide-ion concentration at 25°C?

**15.56** A solution is 0.030 M  $\text{HNO}_3$  (nitric acid). What is the hydronium-ion concentration at 25°C? What is the hydroxide-ion concentration at 25°C?

**15.57** What are the hydronium-ion and the hydroxide-ion concentrations of a solution at 25°C that is 0.0085 M barium hydroxide,  $\text{Ba}(\text{OH})_2$ ?

**15.58** A saturated solution of magnesium hydroxide is  $3.2 \times 10^{-4}$  M  $\text{Mg}(\text{OH})_2$ . What are the hydronium-ion and hydroxide-ion concentrations in the solution at 25°C?

**15.59** The following are solution concentrations. Indicate whether each solution is acidic, basic, or neutral.

- a**  $5 \times 10^{-6}$  M  $\text{H}_3\text{O}^+$                       **b**  $5 \times 10^{-9}$  M  $\text{OH}^-$   
**c**  $1 \times 10^{-7}$  M  $\text{OH}^-$                       **d**  $2 \times 10^{-9}$  M  $\text{H}_3\text{O}^+$

**15.60** The following are solution concentrations. Indicate whether each solution is acidic, basic, or neutral.

- a**  $2 \times 10^{-11}$  M  $\text{OH}^-$                       **b**  $2 \times 10^{-6}$  M  $\text{H}_3\text{O}^+$   
**c**  $6 \times 10^{-10}$  M  $\text{OH}^-$                       **d**  $6 \times 10^{-3}$  M  $\text{H}_3\text{O}^+$

**15.61** A shampoo solution at 25°C has a hydroxide-ion concentration of  $1.5 \times 10^{-9}$  M. Is the solution acidic, neutral, or basic?

**15.62** An antiseptic solution at 25°C has a hydroxide-ion concentration of  $8.4 \times 10^{-5}$  M. Is the solution acidic, neutral, or basic?

### Calculations Involving pH

**15.63** Which of the following pH values indicate an acidic solution at 25°C? Which are basic and which are neutral?

- a** 4.6                      **b** 7.0                      **c** 1.6                      **d** 10.5

**15.64** Which of the following pH values indicate an acidic solution at 25°C? Which are basic and which are neutral?

- a** 12.9                      **b** 8.9                      **c** 5.1                      **d** 1.6

**15.65** For each of the following, state whether the solution at 25°C is acidic, neutral, or basic: **a** A beverage solution has a pH of 3.5. **b** A 0.50 M solution of potassium bromide,  $\text{KBr}$ , has a pH of 7.0. **c** A 0.050 M solution of

pyridine,  $\text{C}_5\text{H}_5\text{N}$ , has a pH of 9.0. **d** A solution of iron(III) chloride has a pH of 5.5.

**15.66** For each of the following, state whether the solution at 25°C is acidic, neutral, or basic: **a** A 0.1 M solution of trisodium phosphate,  $\text{Na}_3\text{PO}_4$ , has a pH of 12.0. **b** A 0.1 M solution of calcium chloride,  $\text{CaCl}_2$ , has a pH of 7.0. **c** A 0.2 M solution of copper(II) sulfate,  $\text{CuSO}_4$ , has a pH of 4.0. **d** A sample of rainwater has a pH of 5.7.

**15.67** Obtain the pH corresponding to the following hydronium-ion concentrations.

- a**  $1.0 \times 10^{-8}$  M                              **b**  $5.0 \times 10^{-12}$  M  
**c**  $7.5 \times 10^{-3}$  M                              **d**  $6.35 \times 10^{-9}$  M

**15.68** Obtain the pH corresponding to the following hydronium-ion concentrations.

- a**  $1.0 \times 10^{-4}$  M                              **b**  $3.2 \times 10^{-10}$  M  
**c**  $2.3 \times 10^{-5}$  M                              **d**  $2.91 \times 10^{-11}$  M

**15.69** A sample of vinegar has a hydronium-ion concentration of  $3.0 \times 10^{-3}$  M. What is the pH of the vinegar?

**15.70** Some lemon juice has a hydronium-ion concentration of  $5.0 \times 10^{-3}$  M. What is the pH of the lemon juice?

**15.71** Obtain the pH corresponding to the following hydroxide-ion concentrations.

- a**  $4.35 \times 10^{-9}$  M                              **b**  $7.3 \times 10^{-3}$  M  
**c**  $2.6 \times 10^{-12}$  M                              **d**  $1.1 \times 10^{-8}$  M

**15.72** Obtain the pH corresponding to the following hydroxide-ion concentrations.

- a**  $4.83 \times 10^{-11}$  M                              **b**  $3.2 \times 10^{-5}$  M  
**c**  $2.7 \times 10^{-10}$  M                              **d**  $5.0 \times 10^{-4}$  M

**15.73** A solution of washing soda (sodium carbonate,  $\text{Na}_2\text{CO}_3$ ) has a hydroxide-ion concentration of 0.0040 M. What is the pH at 25°C?

**15.74** A solution of lye (sodium hydroxide,  $\text{NaOH}$ ) has a hydroxide-ion concentration of 0.050 M. What is the pH at 25°C?

**15.75** The pH of a cup of coffee (at 25°C) was found to be 5.12. What is the hydronium-ion concentration?

**15.76** A wine was tested for acidity, and its pH was found to be 3.85 at 25°C. What is the hydronium-ion concentration?

**15.77** A detergent solution has a pH of 11.80 at 25°C. What is the hydroxide-ion concentration?

**15.78** Morphine is a narcotic that is used to relieve pain. A solution of morphine has a pH of 9.61 at 25°C. What is the hydroxide-ion concentration?

**15.79** A 1.00-L aqueous solution contained 5.80 g of sodium hydroxide,  $\text{NaOH}$ . What was the pH of the solution at 25°C?

**15.80** A 1.00-L aqueous solution contained 6.78 g of barium hydroxide,  $\text{Ba}(\text{OH})_2$ . What was the pH of the solution at 25°C?

**15.81** A certain sample of rainwater gives a yellow color with methyl red and a yellow color with bromthymol blue. What is the approximate pH of the water? Is the rainwater acidic, neutral, or basic? (See Figure 15.10.)

**15.82** A drop of thymol blue gave a yellow color with a solution of aspirin. A sample of the same aspirin solution gave a yellow color with bromphenol blue. What was the pH of the solution? Was the solution acidic, neutral, or basic? (See Figure 15.10.)

## General Problems

**Key:** These problems provide more practice but are not divided by topic or keyed to exercises. Each section ends with essay questions, each of which is color coded to refer to the *A Chemist Looks at Life Science* (pink) and *A Chemist Looks at Daily Life* (orange) chapter essay on which it is based. Odd-numbered problems and the even-numbered problems that follow are similar; answers to all odd-numbered problems except the essay questions are given in the back of the book.

**15.83** Identify each of the following as an acid or a base in terms of the Arrhenius concept. Give the chemical equation for the reaction of the substance with water, showing the origin of the acidity or basicity.

- a** BaO    **b** H<sub>2</sub>S    **c** CH<sub>3</sub>NH<sub>2</sub>    **d** SO<sub>2</sub>

**15.84** Which of the following substances are acids in terms of the Arrhenius concept? Which are bases? Show the acid or base character by using chemical equations.

- a** P<sub>4</sub>O<sub>10</sub>    **b** Na<sub>2</sub>O    **c** N<sub>2</sub>H<sub>4</sub>    **d** H<sub>2</sub>Te

**15.85** Write a reaction for each of the following in which the species acts as a Brønsted acid. The equilibrium should favor the product side.

- a** H<sub>2</sub>O<sub>2</sub>    **b** HCO<sub>3</sub><sup>-</sup>    **c** NH<sub>4</sub><sup>+</sup>    **d** H<sub>2</sub>PO<sub>4</sub><sup>-</sup>

**15.86** Write a reaction for each of the following in which the species acts as a Brønsted base. The equilibrium should favor the product side.

- a** HCO<sub>3</sub><sup>-</sup>    **b** H<sub>2</sub>O    **c** H<sub>2</sub>PO<sub>4</sub><sup>-</sup>    **d** NH<sub>3</sub>

**15.87** For each of the following, write the complete chemical equation for the acid–base reaction that occurs. Describe each using Brønsted language (if appropriate) and then using Lewis language (show electron-dot formulas).

- a** The ClO<sup>-</sup> ion reacts with water.  
**b** The reaction of NH<sub>4</sub><sup>+</sup> and NH<sub>2</sub><sup>-</sup> in liquid ammonia to produce NH<sub>3</sub>.

**15.88** For each of the following, write the complete chemical equation for the acid–base reaction that occurs. Describe each using Brønsted language (if appropriate) and then using Lewis language (show electron-dot formulas).

- a** The HS<sup>-</sup> ion reacts in water to produce H<sub>2</sub>S.  
**b** Cyanide ion, CN<sup>-</sup>, reacts with Fe<sup>3+</sup>.

**15.89** Complete the following proton-transfer reaction. Decide on the basis of relative acid strengths whether the reaction is more likely to go in the direction written or in the opposite direction.

**15.90** Complete the following reaction. Decide on the basis of relative acid strengths whether the reaction is more likely to go in the direction written or in the opposite direction.

**15.91** List the following compounds in order of increasing acid strength: HBr, H<sub>2</sub>Se, H<sub>2</sub>S.

**15.92** List the following compounds in order of increasing acid strength: HBrO<sub>2</sub>, HClO<sub>2</sub>, HBrO.

**15.93** A solution is 0.18 M KOH. What are the concentrations of H<sub>3</sub>O<sup>+</sup> and OH<sup>-</sup> in this solution?

**15.94** A solution is 0.25 M Sr(OH)<sub>2</sub>. What are the concentrations of H<sub>3</sub>O<sup>+</sup> and OH<sup>-</sup> in this solution?

**15.95** A wine has a hydronium-ion concentration equal to 1.5 × 10<sup>-3</sup> M. What is the pH of this wine?

**15.96** A sample of lemon juice has a hydronium-ion concentration equal to 2.6 × 10<sup>-2</sup> M. What is the pH of this sample?

**15.97** A sample of apple cider has a pH of 3.75. What is the hydroxide-ion concentration of this solution?

**15.98** A sample of grape juice has a pH of 4.15. What is the hydroxide-ion concentration of this solution?

**15.99** A 4.640-g sample of a mixture of sodium hydrogen carbonate and potassium chloride is dissolved in 25.20 mL of 0.444 M H<sub>2</sub>SO<sub>4</sub>. Some acid remains after treatment of the sample.

- a** Write both the net ionic and the molecular equations for the complete reaction of sodium hydrogen carbonate with sulfuric acid.  
**b** If 34.8-mL of 0.109 M NaOH were required to titrate the excess sulfuric acid, how many moles of sodium hydrogen carbonate were present in the original sample?  
**c** What is the percent composition of the original sample?

**15.100** A 2.500-g sample of a mixture of sodium carbonate and sodium chloride is dissolved in 25.00 mL of 0.798 M HCl. Some acid remains after the treatment of the sample.

- a** Write the net ionic equation for the complete reaction of sodium carbonate with hydrochloric acid.  
**b** If 28.7 mL of 0.108 M NaOH were required to titrate the excess hydrochloric acid, how many moles of sodium carbonate were present in the original sample?  
**c** What is the percent composition of the original sample?

**15.101** The bicarbonate ion has the ability to act as an acid in the presence of a base or as a base in the presence of an acid, so it is said to be amphiprotic. Illustrate this behavior with water by writing Brønsted–Lowry acid–base reactions. Also illustrate this property by selecting a common strong acid and base to react with the bicarbonate ion.

**15.102** The dihydrogen phosphate ion has the ability to act as an acid in the presence of a base and as a base in the presence of an acid. What is this property called? Illustrate this behavior with water by writing Brønsted–Lowry acid–base reactions. Also illustrate this property by selecting a common acid and base to react with the dihydrogen phosphate ion.

**15.103** The hydride ion does not exist in water because it has a greater attraction for the hydronium ion than the hydroxide ion does. Write the equation for the reaction that occurs when calcium hydride is added to water. Which is the stronger base, the hydride ion or the hydroxide ion? What is the meaning of the statement that the strongest base that can exist in water is the hydroxide ion?

**15.104** The nitride ion and the amide ion, NH<sub>2</sub><sup>-</sup>, have greater attractions for the hydronium ion than the hydroxide ion does. Write the equations for the reactions that

occur when calcium nitride and sodium amide are added to water (each gives  $\text{NH}_3$ ). Which is the stronger base, the nitride ion or the amide ion? Why? What is the meaning of the statement that the hydroxide ion is the strongest base that can exist in water?

- **15.105** Why do medicines frequently taste bitter?
- **15.106** Show how methylamine,  $\text{CH}_3\text{NH}_2$ , is a Brønsted–Lowry base. Is methylamine also a Lewis base? Explain.
- **15.107** Explain how sodium hydroxide dissolves grease and hair from a stopped drain.
- **15.108** How is sodium hydroxide prepared commercially?

## Strategy Problems

**Key:** As noted earlier, all of the practice and general problems are matched pairs. This section is a selection of problems that are not in matched-pair format. These challenging problems require that you employ many of the concepts and strategies that were developed in the chapter. In some cases, you will have to integrate several concepts and operational skills in order to solve the problem successfully.

**15.109** **a** Consider the hydrated aluminum ion  $\text{Al}(\text{H}_2\text{O})_6^{3+}$  as a Brønsted–Lowry acid. Write the chemical equation in which this ion loses a proton in a reaction with ammonia,  $\text{NH}_3$ . Identify the conjugate acids and bases in this reaction. **b** Ethanethiol,  $\text{CH}_3\text{CH}_2\text{SH}$ , is a malodorous compound present in petroleum. It is removed from petroleum by reaction with sulfuric acid. Write a chemical equation for this reaction, identifying acid and base conjugates.

**15.110** Saccharin,  $\text{HC}_7\text{H}_4\text{NO}_3\text{S}$ , is a well-known sweetener. It is a weak acid, and as the sweetener, it is generally supplied as the sodium salt. Here is the structural formula for the saccharin molecule. From the structural formula, decide which H atom is acidic. What is the basis for your decision.

**15.111** Consider the acids listed and decide on the basis of their structures how you would order them, from weakest to strongest. Explain your reasoning.

**15.112** Hydrazine,  $\text{N}_2\text{H}_4$  (having the structure  $\text{H}_2\text{NNH}_2$ ), and its derivatives have been used as rocket fuels. Draw the Lewis electron-dot formula for the hydrazine molecule.

Describe the geometries expected about the nitrogen atoms in this molecule. Why would you expect hydrazine to be basic? Which substance,  $\text{NH}_3$  or  $\text{N}_2\text{H}_4$ , would you expect to be more basic? Why? Write the chemical equation in which hydrazine reacts with hydrochloric acids to form the salt  $\text{N}_2\text{H}_5\text{Cl}$ . Consider the positive ion of this salt. How does its basic character compare with that of  $\text{NH}_3$  and  $\text{N}_2\text{H}_4$ ? Explain.

**15.113** Consider the substances arsine,  $\text{AsH}_3$ , and phosphine,  $\text{PH}_3$ , that are analogous to ammonia,  $\text{NH}_3$ . Write chemical equations illustrating the basic character of arsine and phosphine. Write formulas for the ions formed by  $\text{NH}_3$ ,  $\text{AsH}_3$ , and  $\text{PH}_3$  with  $\text{H}^+$ . Order these ions by their acidic character. Explain how you arrived at this order. Now compare the basicities of the substances  $\text{AsH}_3$ ,  $\text{PH}_3$ , and  $\text{NH}_3$ , ordering them by their basic character, from least to most basic. Explain how you arrived at this order.

**15.114** Liquid ammonia undergoes autoionization similar to that of water:

How would you define an acid and a base similar to the way these terms are defined by the Brønsted–Lowry concept for aqueous solutions? Write the expression for the ion-product constant,  $K_{am}$ , for this autoionization. The value of  $K_{am}$  is  $5.1 \times 10^{-27}$ . What is the concentration of  $\text{NH}_4^+$  in a neutral solution of liquid ammonia? Suppose you dissolve  $\text{NH}_4\text{I}$  in liquid ammonia to give  $\text{NH}_4^+$  and  $\text{I}^-$  ions. Similarly, you dissolve  $\text{KNH}_2$  (potassium amide) in liquid ammonia to give a solution of  $\text{K}^+$  and  $\text{NH}_2^-$  ions. Which of these two solutions is acidic and which basic according to your definitions? Now, suppose you add the two solutions together. Write an equation for the neutralization reaction.

**15.115** Ethanol (ethyl alcohol),  $\text{CH}_3\text{CH}_2\text{OH}$ , can act as a Brønsted–Lowry acid. Write the chemical equation for the reaction of ethanol as an acid with hydroxide ion,  $\text{OH}^-$ . Ethanol can also react as a Brønsted–Lowry base. Write the chemical equation for the reaction of ethanol as a base with hydronium ion,  $\text{H}_3\text{O}^+$ . Explain how you arrived at these chemical equations. Both of these reactions can also be considered Lewis acid–base reactions. Explain this.

**15.116** Ethanol,  $\text{CH}_3\text{CH}_2\text{OH}$ , can undergo auto-ionization. Write the chemical equation for this auto-ionization. Explain how you arrived at this equation. At room temperature, the ion product for this self-ionization is  $1.0 \times 10^{-20}$ . What is the concentration of each ion at this temperature? Show how you arrived at these concentrations.

**15.117** Aluminum chloride,  $\text{AlCl}_3$ , reacts with trimethylamine,  $\text{N}(\text{CH}_3)_3$ . What would you guess to be the product of this reaction? Explain why you think so. Describe the reaction in terms of one of the acid–base concepts. Write an appropriate equation to go with this description. Which substance is the acid according to this acid–base concept? Explain.

**15.118** Consider each of the following pairs of compounds, and indicate which one of each pair is the stronger Lewis acid. Explain how you arrived at your answers.

- a**  $\text{Fe}^{2+}$ ,  $\text{Fe}^{3+}$       **b**  $\text{BF}_3$ ,  $\text{BCl}_3$

**15.119** Arrange each of the following in order of increasing acidity. You may need to use a couple of rules to decide the order for a given series. Explain the reasoning you use in each case.

- a**  $\text{HBrO}_2$ ,  $\text{HBrO}_3$ ,  $\text{HBrO}$   
**b**  $\text{H}_2\text{TeO}_3$ ,  $\text{H}_2\text{SO}_3$ ,  $\text{H}_2\text{SeO}_3$   
**c**  $\text{HI}$ ,  $\text{SbH}_3$ ,  $\text{H}_2\text{Te}$   
**d**  $\text{H}_2\text{S}$ ,  $\text{HBr}$ ,  $\text{H}_2\text{Se}$   
**e**  $\text{HClO}_2$ ,  $\text{HClO}_3$ ,  $\text{HBrO}_2$

**15.120** The following is a table of some of the oxoacids of the halogens. Which acid in the table is the strongest? Which is the weakest? Explain how you arrived at your answers.

<i>Chlorine</i>	<i>Bromine</i>	<i>Iodine</i>
$\text{HOCl}$	$\text{HOBr}$	$\text{HOI}$
$\text{HOClO}$	$\text{HOBrO}$	$\text{HOIO}$
$\text{HOClO}_2$	$\text{HOBrO}_2$	$\text{HOIO}_2$

**15.121** Suppose you have 557 mL of 0.0300 M HCl, and you want to make up a solution of HCl that has a pH of 1.751. What is the maximum volume (in liters) that you can make of this solution?

**15.122** How many grams of water are in dissociated form (as  $\text{H}^+$  and  $\text{OH}^-$  ions) in 1.00 L of pure water? How many hydrogen ions,  $\text{H}^+(\text{aq})$ , are there in 1.00 L of pure water?

**15.123** You want to make up 3.00 L of aqueous hydrochloric acid,  $\text{HCl}(\text{aq})$ , that has a pH of 2.00. How many grams of concentrated hydrochloric acid will you need? Concentrated hydrochloric acid contains 37.2 mass percent of HCl.

**15.124** You can obtain the pH of a 0.100 M HCl solution by assuming that all of the  $\text{H}_3\text{O}^+$  ion comes from the HCl,

in which case the pH equals  $-\log 0.100 = 1.00$ . But if you want the pH of a solution that is  $1.00 \times 10^{-7}$  M HCl, you also need to account for  $\text{H}_3\text{O}^+$  ion coming from water. (Why?) Note that the auto-ionization of water is the only equilibrium you need to account for. What is the pH of  $1.00 \times 10^{-7}$  M HCl?

**15.125** Pure liquid hydrogen fluoride ionizes in a way similar to that of water.

- a** Write the equilibrium reaction for the auto-ionization of liquid hydrogen fluoride.  
**b** Will sodium fluoride be an acid or a base in liquid hydrogen fluoride? Why?  
**c** Perchloric acid is a strong acid in liquid hydrogen fluoride. Write the chemical equation for the ionization reaction. What is the conjugate acid in this medium?

**15.126** Pure liquid ammonia ionizes in a way similar to that of water.

- a** Write the equilibrium reaction of liquid ammonia.  
**b** Will sodium amide,  $\text{NaNH}_2$ , be an acid or a base in liquid ammonia? Why?  
**c** Ammonium chloride can be used to titrate sodium amide in liquid ammonia. Write the chemical equation for the titration of sodium amide with ammonium chloride in liquid ammonia.

**15.127** A solution contains 4.25 g of ammonia per 250.0 mL of solution. Electrical conductivity measurements at 25°C show that 0.42% of the ammonia has reacted with water. Write the equation for this reaction and calculate the pH of the solution.

**15.128** A solution contains 0.675 g of ethylamine,  $\text{C}_2\text{H}_5\text{NH}_2$ , per 100.0 mL of solution. Electrical conductivity measurements at 20°C show that 0.98% of the ethylamine has reacted with water. Write the equation for this reaction. Calculate the pH of the solution.

## Capstone Problems

**Key:** The problems under this heading combine skills, strategies, and concepts learned in previous chapters with those introduced in the current one.

**15.129** Phosphorous acid,  $\text{H}_3\text{PO}_3$ , and phosphoric acid,  $\text{H}_3\text{PO}_4$ , have approximately the same acid strengths. From this information, and noting the possibility that one or more hydrogen atoms may be directly bonded to the phosphorus atom, draw the structural formula of phosphorous acid. How many grams of sodium hydroxide would be required to completely neutralize 1.00 g of this acid?

**15.130** Hypophosphorous acid,  $\text{H}_3\text{PO}_2$ , and phosphoric acid,  $\text{H}_3\text{PO}_4$ , have approximately the same acid strengths. From this information, and noting the possibility that one or more hydrogen atoms may be directly bonded to the phosphorus atom, draw the structural formula of hypophosphorous acid. How many grams of sodium hydroxide would be required to completely neutralize 1.00 g of this acid?

**15.131** Boron trifluoride,  $\text{BF}_3$ , and ammonia,  $\text{NH}_3$ , react to produce  $\text{BF}_3 \cdot \text{NH}_3$ . A coordinate covalent bond is formed between the boron atom on  $\text{BF}_3$  and the nitrogen atom on  $\text{NH}_3$ . Write the equation for this reaction, using Lewis electron-dot formulas. Label the Lewis acid and the Lewis base. Determine how many grams of  $\text{BF}_3 \cdot \text{NH}_3$  are formed when 10.0 g  $\text{BF}_3$  and 10.0 g  $\text{NH}_3$  are placed in a reaction vessel, assuming that the reaction goes to completion.

**15.132** Boron trifluoride,  $\text{BF}_3$ , and diethyl ether,  $(\text{C}_2\text{H}_5)_2\text{O}$ , react to produce a compound with the formula  $\text{BF}_3 \cdot (\text{C}_2\text{H}_5)_2\text{O}$ . A coordinate covalent bond is formed between the boron atom on  $\text{BF}_3$  and the oxygen atom on  $(\text{C}_2\text{H}_5)_2\text{O}$ . Write the equation for this reaction, using Lewis electron-dot formulas. Label the Lewis acid and the Lewis base. Determine how many grams of  $\text{BF}_3 \cdot (\text{C}_2\text{H}_5)_2\text{O}$  are formed when 9.10 g  $\text{BF}_3$  and 23.3 g  $(\text{C}_2\text{H}_5)_2\text{O}$  are placed in a reaction vessel, assuming that the reaction goes to completion.

## 16

## Acid–Base Equilibria

Limestone, which is mainly  $\text{CaCO}_3$ , is slightly soluble in acidic solution, so limestone statues are easily damaged by acid rain. The basic property of limestone makes the powdered form useful as a soil conditioner, to adjust soil pH. Sulfuric acid is a component of acid rain; a major commercial use of this acid is to produce fertilizers, such as ammonium phosphate, from phosphate rock.

## CONTENTS AND CONCEPTS

**Solutions of a Weak Acid or Base**

We will investigate the reactions and equilibrium calculations of weak acids, weak bases, and salts in aqueous solution.

- 16.1 Acid-Ionization Equilibria
- 16.2 Polyprotic Acids

**16.3** Base-Ionization Equilibria**16.4** Acid–Base Properties of Salt Solutions**Solutions of a Weak Acid or Base with Another Solute**

We now take the opportunity to see how the pH of weak acids and weak bases is affected by the addition of a solute.

**16.5** Common-Ion Effect**16.6** Buffers**16.7** Acid–Base Titration Curves

Many well-known substances are weak acids or bases. The following are weak acids: aspirin (acetylsalicylic acid, a headache remedy), phenobarbital (a sedative), saccharin (a sweetener), and niacin (nicotinic acid, a B vitamin). That these are *weak* acids means that their reactions with water do not go to completion. To discuss such acid–base reactions, you need to look at the equilibria involved and be able to calculate the concentrations of species in a reaction mixture.

Consider, for example, how you could answer the following questions: What is the hydronium-ion concentration of 0.10 *M* niacin (nicotinic acid)? What is the hydronium-ion concentration of the solution obtained by dissolving one 5.00-grain tablet of aspirin (acetylsalicylic acid) in 0.500 L of water? If these were solutions of strong acids, the calculations would be simple; 0.10 *M* monoprotic acid would yield 0.10 *M* H<sub>3</sub>O<sup>+</sup> ion. However, because niacin is a weak monoprotic acid, the H<sub>3</sub>O<sup>+</sup> concentration is less than 0.10 *M*. To find the concentration, you need the equilibrium constant for the reaction involved, and you need to solve an equilibrium problem.

A similar process is involved in finding the hydronium-ion concentration of 0.10 *M* sodium nicotinate (sodium salt of niacin). In this case, you need to look at the acid–base equilibrium of the nicotinate ion. Let us see how you answer questions of this sort.

## ► Solutions of a Weak Acid or Base

The simplest acid–base equilibria are those in which a single acid or base solute reacts with water. We will look first at solutions of weak acids, next at solutions of weak bases. Then we will consider solutions of salts, which can have acidic or basic properties as a result of reactions of their ions with water.

### 16.1 Acid-Ionization Equilibria

An acid reacts with water to produce hydronium ion (hydrogen ion) and the conjugate base ion. The process is called *acid ionization* or *acid dissociation*. Consider an aqueous solution of the weak acid acetic acid, HC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>, the sour constituent of vinegar (Figure 16.1). When the acid is added to water, it reacts according to the equation

**Figure 16.1** ▲

**The structure of acetic acid** *Left:* Structural formula. Only the hydrogen atom (in color) attached to the oxygen atom is acidic. The hydrogen atoms attached to carbon are not acidic. The acidic group

(often written —COOH and called the carboxylic acid group) occurs in many organic acids. *Right:* Electrostatic potential map of acetic acid.

Because acetic acid is a weak electrolyte, the acid *ionizes* to a small extent in water (about 5% or less, depending on the concentration of acid).

For a strong acid, which ionizes completely in solution, the concentrations of ions are determined by the stoichiometry of the reaction from the initial concentration of acid. However, for a weak acid such as acetic acid, the concentrations of ions in solution are determined from the **acid-ionization constant** (also called the acid-dissociation constant), which is *the equilibrium constant for the ionization of a weak acid*.

To find the acid-ionization constant, write HA for the general formula of a weak, monoprotic acid. The acid-ionization equilibrium in aqueous solution is

The corresponding equilibrium constant is

$$K_c = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}][\text{H}_2\text{O}]}$$

Assuming that this is a dilute solution and that the reaction occurs to only a small extent, the concentration of water will be nearly constant. Rearranging this equation gives

$$K_a = [\text{H}_2\text{O}]K_c = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]}$$

Thus,  $K_a$ , the acid-ionization constant, equals the constant  $[\text{H}_2\text{O}]K_c$  ▶

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]}$$

### Experimental Determination of $K_a$

The ionization constant for a weak acid is usually determined experimentally by one of two methods. In one method, the electrical conductivity or some colligative property of a solution of the acid is measured to obtain its degree of ionization. The **degree of ionization** of a weak electrolyte is *the fraction of molecules that react with water to give ions*. This may also be expressed as a percentage, giving the *percent ionization*. In the other method, the pH of a solution of the weak acid is determined. From the pH one finds the concentration of  $\text{H}_3\text{O}^+$  ion and then the concentrations of other ions. The following example shows how to calculate  $K_a$  from the pH of a solution of nicotinic acid (Figure 16.2). It also shows how to calculate the degree of ionization and the percent ionization.

In terms of the thermodynamic equilibrium constant, the activity of  $\text{H}_2\text{O}$  is nearly constant and essentially 1, so it does not appear explicitly in the equilibrium constant.

The structural formula of nicotinic acid (niacin); note the acidic hydrogen atom (in color). Nicotinic acid was first prepared by oxidizing nicotine, a basic substance present in tobacco.

**Figure 16.2** ▲  
The structure of nicotinic acid

### Example 16.1 Determining $K_a$ from the Solution pH

#### Gaining Mastery Toolbox

##### Critical Concept 16.1

Weak acids are partially ionized in solution. Therefore, calculating the pH or  $[\text{H}_3\text{O}^+]$  of a weak acid solution requires performing an equilibrium calculation. Equilibrium calculations were introduced in Chapter 14.

##### Solution Essentials:

- Acid ionization constant ( $K_a$ )
- Degree of ionization
- pH

Nicotinic acid (niacin) is a monoprotic acid with the formula  $\text{HC}_6\text{H}_4\text{NO}_2$ . A solution that is 0.012 M in nicotinic acid has a pH of 3.39 at 25°C. What is the acid-ionization constant,  $K_a$ , for this acid at 25°C? What is the degree of ionization of nicotinic acid in this solution?

**Problem Strategy** It is important to realize that when we say the solution is 0.012 M, this refers to *how the solution is prepared*. The solution is made up by adding 0.012 mol of substance to enough water to give a liter of solution. Once the solution is prepared, some molecules ionize, so the actual concentration is somewhat less than 0.012 M. To solve for  $K_a$ , you follow the three steps outlined in Chapter 14 for solving equilibrium problems.

(continued)

**Example 16.1** (continued)

- Weak acid
- Acid
- Equilibrium-constant expression
- Concentration (molarity)

**Solution**

**Step 1:** Abbreviate the formula for nicotinic acid as HNic. Then 1 L of solution contains 0.012 mol HNic and 0 mol  $\text{Nic}^-$ , the acid anion, before ionization. The  $\text{H}_3\text{O}^+$  concentration at the start is that from the self-ionization of water. It is usually much smaller than that obtained from the acid (unless the solution is extremely dilute or  $K_a$  is quite small), so you can write  $[\text{H}_3\text{O}^+] = \sim 0$  (meaning approximately zero). If  $x$  mol HNic ionizes,  $x$  mol each of  $\text{H}_3\text{O}^+$  and  $\text{Nic}^-$  is formed, leaving  $(0.012 - x)$  mol HNic in solution. You can summarize the situation as follows:

Concentration (M)	$\text{HNic}(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{H}_3\text{O}^+(\text{aq}) + \text{Nic}^-(\text{aq})$		
Starting	0.012	$\sim 0$	0
Change	$-x$	$+x$	$+x$
Equilibrium	$0.012 - x$	$x$	$x$

Thus, the molar concentrations of HNic,  $\text{H}_3\text{O}^+$ , and  $\text{Nic}^-$  at equilibrium are  $(0.012 - x)$ ,  $x$ , and  $x$ , respectively.

**Step 2:** The equilibrium-constant equation is

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{Nic}^-]}{[\text{HNic}]}$$

When you substitute the expressions for the equilibrium concentrations, you get

$$K_a = \frac{x^2}{(0.012 - x)}$$

**Step 3:** The value of  $x$  equals the numerical value of the molar hydronium-ion concentration and can be obtained from the pH of the solution.

$$x = [\text{H}_3\text{O}^+] = \text{antilog}(-\text{pH}) = \text{antilog}(-3.39) = 4.1 \times 10^{-4} = 0.00041$$

You can substitute this value of  $x$  into the equation obtained in Step 2. Note first, however, that

$$0.012 - x = 0.012 - 0.00041 = 0.01159 \approx 0.012 \quad (\text{to two significant figures})$$

This means that the concentration of undissolved acid is equal to the original concentration of the acid within the precision of the data. (We will make use of this type of observation in later problem solving.) Therefore,

$$K_a = \frac{x^2}{(0.012 - x)} \approx \frac{x^2}{0.012} \approx \frac{(0.00041)^2}{0.012} = 1.4 \times 10^{-5}$$

To obtain the degree of ionization, note that  $x$  mol out of 0.012 mol of nicotinic acid ionizes. Hence,

$$\text{Degree of ionization} = \frac{x}{0.012} = \frac{0.00041}{0.012} = 0.034$$

The percent ionization is obtained by multiplying this by 100, which gives 3.4%.

**Answer Check** In order to be a weak acid, the  $K_a$  value must be very small, as it is here. Therefore, if you calculate a  $K_a$  for a weak acid that is greater than  $10^{-1}$ , you should check for errors in your work.

**Exercise 16.1** Lactic acid,  $\text{HC}_3\text{H}_5\text{O}_3$ , is found in sour milk, where it is produced by the action of lactobacilli on lactose, or milk sugar. A 0.025 M solution of lactic acid has a pH of 2.75. What is the ionization constant  $K_a$  for this acid? What is the degree of ionization? ◀

See Problems 16.35 and 16.36.

Lactic acid has the structural formula

and the electrostatic potential map

Table 16.1 Acid-Ionization Constants at 25°C*		
Substance	Formula	$K_a$
Acetic acid	$\text{HC}_2\text{H}_3\text{O}_2$	$1.7 \times 10^{-5}$
Benzoic acid	$\text{HC}_7\text{H}_5\text{O}_2$	$6.3 \times 10^{-5}$
Boric acid	$\text{H}_3\text{BO}_3$	$5.9 \times 10^{-10}$
Carbonic acid	$\text{H}_2\text{CO}_3$	$4.3 \times 10^{-7}$
	$\text{HCO}_3^-$	$4.8 \times 10^{-11}$
Cyanic acid	$\text{HOCN}$	$3.5 \times 10^{-4}$
Formic acid	$\text{HCHO}_2$	$1.7 \times 10^{-4}$
Hydrocyanic acid	$\text{HCN}$	$4.9 \times 10^{-10}$
Hydrofluoric acid	$\text{HF}$	$6.8 \times 10^{-4}$
Hydrogen sulfate ion	$\text{HSO}_4^-$	$1.1 \times 10^{-2}$
Hydrogen sulfide	$\text{H}_2\text{S}$	$8.9 \times 10^{-8}$
	$\text{HS}^-$	$1.2 \times 10^{-13}\dagger$
Hypochlorous acid	$\text{HClO}$	$3.5 \times 10^{-8}$
Nitrous acid	$\text{HNO}_2$	$4.5 \times 10^{-4}$
Oxalic acid	$\text{H}_2\text{C}_2\text{O}_4$	$5.6 \times 10^{-2}$
	$\text{HC}_2\text{O}_4^-$	$5.1 \times 10^{-5}$
Phosphoric acid	$\text{H}_3\text{PO}_4$	$6.9 \times 10^{-3}$
	$\text{H}_2\text{PO}_4^-$	$6.2 \times 10^{-8}$
	$\text{HPO}_4^{2-}$	$4.8 \times 10^{-13}$
Phosphorous acid	$\text{H}_2\text{PHO}_3$	$1.6 \times 10^{-2}$
	$\text{H}_2\text{PHO}_3^-$	$7 \times 10^{-7}$
Propionic acid	$\text{HC}_3\text{H}_5\text{O}_2$	$1.3 \times 10^{-5}$
Pyruvic acid	$\text{HC}_3\text{H}_3\text{O}_3$	$1.4 \times 10^{-4}$
Sulfurous acid	$\text{H}_2\text{SO}_3$	$1.3 \times 10^{-2}$
	$\text{HSO}_3^-$	$6.3 \times 10^{-8}$

\*The ionization constants for polyprotic acids are for successive ionizations. For example, for  $\text{H}_3\text{PO}_4$ , the equilibrium is  $\text{H}_3\text{PO}_4 + \text{H}_2\text{O} \rightleftharpoons \text{H}_3\text{O}^+ + \text{H}_2\text{PO}_4^-$ . For  $\text{H}_2\text{PO}_4^-$ , the equilibrium is  $\text{H}_2\text{PO}_4^- + \text{H}_2\text{O} \rightleftharpoons \text{H}_3\text{O}^+ + \text{HPO}_4^{2-}$ .

†This value is in doubt. Some evidence suggests that it is about  $10^{-19}$ . See R. J. Myers, *J. Chem. Educ.*, **63**, 687 (1986).

Table 16.1 lists acid-ionization constants for various weak acids. The weakest acids have the smallest values of  $K_a$ .

### Calculations with $K_a$

Once you know the value of  $K_a$  for an acid  $\text{HA}$ , you can calculate the equilibrium concentrations of species  $\text{HA}$ ,  $\text{A}^-$ , and  $\text{H}_3\text{O}^+$  for solutions of different molarities. The general method for doing this was discussed in Chapter 14. Here we illustrate the use of a simplifying approximation that can often be used for weak acids. In the next example, we will look at an amplification of the first question posed in the chapter opening.

### Example 16.2 Calculating Concentrations of Species in a Weak Acid Solution Using $K_a$ (Approximation Method)

#### Gaining Mastery Toolbox

##### Critical Concept 16.2

In some cases, assumptions can be made that simplify equilibrium calculations. When making an assumption, it is essential that you perform a final check to see if the assumption is valid. For our purposes, the assumption is generally valid if it introduces an error of 5% or less.

##### Solution Essentials:

- Acid ionization constant ( $K_a$ )
- Degree of ionization
- pH
- Weak acid
- Acid
- Equilibrium-constant expression

What are the concentrations of nicotinic acid, hydrogen ion, and nicotinate ion in a solution of 0.10  $M$  nicotinic acid,  $\text{HC}_6\text{H}_4\text{NO}_2$ , at 25°C? What is the pH of the solution? What is the degree of ionization of nicotinic acid? The acid-ionization constant,  $K_a$ , was determined in the previous example to be  $1.4 \times 10^{-5}$ .

**Problem Strategy** You follow the three steps for solving equilibrium problems that were introduced in Example 14.7. In the last step, you solve the equilibrium-constant equation for the equilibrium concentrations. The resulting equation is quadratic, but because the equilibrium concentration of a weak acid is usually negligibly different from its starting value, the equation simplifies so that it involves only the square of the unknown, which is easily solved by taking the square root. (You will need to check that this assumption is valid.)

#### Solution

**Step 1:** At the start (before ionization), the concentration of nicotinic acid,  $\text{HNic}$ , is 0.10  $M$  and that of its conjugate base,  $\text{Nic}^-$ , is 0. The concentration of  $\text{H}_3\text{O}^+$  is essentially zero ( $\sim 0$ ), assuming that the contribution from the self-ionization of water can be neglected. In 1 L of solution, the nicotinic acid ionizes to give  $x$  mol  $\text{H}_3\text{O}^+$  and  $x$  mol  $\text{Nic}^-$ , leaving  $(0.10 - x)$  mol of nicotinic acid. These data are summarized in the following table:

Concentration (M)	$\text{HNic(aq)} + \text{H}_2\text{O(l)} \rightleftharpoons \text{H}_3\text{O}^+(\text{aq}) + \text{Nic}^-(\text{aq})$		
Starting	0.10	$\sim 0$	0
Change	$-x$	$+x$	$+x$
Equilibrium	$0.10 - x$	$x$	$x$

The equilibrium concentrations of  $\text{HNic}$ ,  $\text{H}_3\text{O}^+$ , and  $\text{Nic}^-$  are  $(0.10 - x)$ ,  $x$ , and  $x$ , respectively.

**Step 2:** Now substitute these concentrations and the value of  $K_a$  into the equilibrium-constant equation for acid ionization:

$$\frac{[\text{H}_3\text{O}^+][\text{Nic}^-]}{[\text{HNic}]} = K_a$$

You get

$$\frac{x^2}{(0.10 - x)} = 1.4 \times 10^{-5}$$

**Step 3:** Now solve this equation for  $x$ . This is actually a quadratic equation, but it can be simplified so that the value of  $x$  is easily found. Because the acid-ionization constant is small, the value of  $x$  is small. Assume that  $x$  is much smaller than 0.10, so that

$$0.10 - x \approx 0.10$$

You will need to check that this assumption is valid after you obtain a value for  $x$ . The equilibrium-constant equation becomes

$$\frac{x^2}{0.10} \approx 1.4 \times 10^{-5}$$

or

$$x^2 \approx 1.4 \times 10^{-5} \times 0.10 = 1.4 \times 10^{-6}$$

Hence,

$$x \approx 1.2 \times 10^{-3} = 0.0012$$

(continued)

**Example 16.2** (continued)

At this point, you should check to make sure that the assumption  $0.10 - x \approx 0.10$  is valid. You substitute the value obtained for  $x$  into  $0.10 - x$ .

$$0.10 - x = 0.10 - 0.0012 = 0.10 \quad (\text{to two significant figures})$$

The assumption is indeed valid.

Now you can substitute the value of  $x$  into the last line of the table written in Step 1 to find the concentrations of species. The concentrations of nicotinic acid, hydronium ion, and nicotinate ion are **0.10 M**, **0.0012 M**, and **0.0012 M**, respectively.

The pH of the solution is

$$\text{pH} = -\log [\text{H}_3\text{O}^+] = -\log (0.0012) = \mathbf{2.92}$$

The degree of ionization equals the amount per liter of nicotinic acid that ionizes ( $x = 0.0012$ ) divided by the total amount per liter of nicotinic acid initially present (0.10). Thus, the degree of ionization is  $0.0012/0.10 = \mathbf{0.012}$ .

**Answer Check** As a quick check on your work, substitute the concentrations that you calculated for the acid (nicotinic), its conjugate base (nicotinate), and hydronium ion into the equilibrium expression for  $K_a$ . You should get the value of  $K_a$  given in the problem.

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{Nic}^-]}{[\text{HNic}]} = \frac{0.0012 \times 0.0012}{0.10} = 1.4 \times 10^{-5}$$

The pH, of course, should be in the acid range, below 7. Check that this is the case.

**Exercise 16.2** What are the concentrations of hydrogen ion and acetate ion in a solution of 0.10 M acetic acid,  $\text{HC}_2\text{H}_3\text{O}_2$ ? What is the pH of the solution? What is the degree of ionization? See Table 16.1 for the value of  $K_a$ .

See Problems 16.37 and 16.38.

In Example 16.2, the degree of ionization of nicotinic acid (0.012) is relatively small in a 0.10 M solution. That is, only 1.2% of the molecules ionize. It is the small value of the degree of ionization that allows you to neglect  $x$  in the term  $0.10 - x$  and thereby simplify the calculation.

The degree of ionization of a weak acid depends on both  $K_a$  and the concentration of the acid solution. For a given concentration, the larger the  $K_a$ , the greater is the degree of ionization. For a given value of  $K_a$ , however, the more dilute the solution, the greater is the degree of ionization. Figure 16.3 shows how the percent ionization (degree of ionization  $\times 100$ ) varies with the concentration of solution.

How do you know when you can use the simplifying assumption of Example 16.2, where you neglected  $x$  in the denominator of the equilibrium equation? *It can be shown that this simplifying assumption gives an error of less than 5% if the concentration of acid,  $C_a$ , divided by  $K_a$  equals 100 or more.* For example, for an acid concentration of  $10^{-2}$  M and  $K_a$  of  $10^{-5}$ ,  $C_a/K_a = 10^{-2}/10^{-5} = 10^3$ , so the assumption is valid. It would not be valid, however, if the concentration of the same acid were  $10^{-4}$  M.

If the simplifying assumption of Example 16.2 is not valid, you can solve the equilibrium equation exactly by using the *quadratic formula*. We illustrate this in the next example with a solution of aspirin,  $\text{HC}_9\text{H}_7\text{O}_4$ , a common headache remedy. (Figure 16.4 shows the structural formula.)

**Figure 16.3** ▲  
**Variation of percent ionization of a weak acid with concentration**  
On this curve for nicotinic acid, note that the percent ionization is greatest for the most dilute solutions.

**Example 16.3** Calculating Concentrations of Species in a Weak Acid Solution Using  $K_a$  (Quadratic Formula)**Gaining Mastery Toolbox****Critical Concept 16.3**

Some equilibrium problems require an exact solution (no assumptions). When the concentration of acid  $C_a$  divided by  $K_a$  is less than 100 ( $C_a/K_a < 100$ ) no assumptions should be made when solving the problem. This approach of prechecking an assumption limits errors to 5% or less.

**Solution Essentials:**

- Acid ionization constant ( $K_a$ )
- pH
- Relative strengths of acids and bases
- Equilibrium-constant expression
- Quadratic formula

What is the pH at 25°C of the solution obtained by dissolving a 5.00-grain tablet of aspirin (acetylsalicylic acid) in 0.500 L of water? The tablet contains 5.00 grains, or 0.325 g, of acetylsalicylic acid,  $\text{HC}_9\text{H}_7\text{O}_4$ . The acid is monoprotic, and  $K_a$  equals  $3.3 \times 10^{-4}$  at 25°C.

**Problem Strategy** You follow the three steps for equilibrium problems. However, the approximation used in the previous example to solve the equilibrium-constant equation is not valid here. Verify this by calculating  $C_a/K_a$ ; it is not greater than 100. You solve the equation exactly using the quadratic formula.

**Solution** The molar mass of  $\text{HC}_9\text{H}_7\text{O}_4$  is 180.2 g. From this you find that an aspirin tablet contains 0.00180 mol of the acid. Hence, the concentration of the aspirin solution is 0.00180 mol/0.500 L, or 0.0036 M. (Retain two significant figures, the number of significant figures in  $K_a$ .)  $C_a/K_a = 0.0036/3.3 \times 10^{-4} = 11$ , which is less than 100, so we must solve the equilibrium equation exactly.

**Step 1:** Abbreviate the formula for acetylsalicylic acid as HAcS and let  $x$  be the amount of  $\text{H}_3\text{O}^+$  ion formed in 1 L of solution. The amount of acetylsalicylate ion formed is also  $x$  mol; the amount of nonionized acetylsalicylic acid is  $(0.0036 - x)$  mol. These data are summarized in the following table:

Concentration (M)	$\text{HAcS(aq)} + \text{H}_2\text{O(l)} \rightleftharpoons \text{H}_3\text{O}^+(\text{aq}) + \text{AcS}^-(\text{aq})$		
Starting	0.0036	~0	0
Change	- $x$	+ $x$	+ $x$
Equilibrium	$0.0036 - x$	$x$	$x$

**Step 2:** If you substitute the equilibrium concentrations and the value of  $K_a$  into the equilibrium-constant equation, you get

$$\frac{[\text{H}_3\text{O}^+][\text{AcS}^-]}{[\text{HAcS}]} = K_a$$

$$\frac{x^2}{0.0036 - x} = 3.3 \times 10^{-4}$$

**Step 3:** You can solve the equation exactly using the quadratic formula. Rearrange the preceding equation to put it in the form  $ax^2 + bx + c = 0$ . You get

$$x^2 = (0.0036 - x) \times 3.3 \times 10^{-4}$$

$$= 1.2 \times 10^{-6} - 3.3 \times 10^{-4} x$$

or

$$x^2 + 3.3 \times 10^{-4} x - 1.2 \times 10^{-6} = 0$$

Now substitute into the quadratic formula.

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

$$= \frac{-3.3 \times 10^{-4} \pm \sqrt{(3.3 \times 10^{-4})^2 + 4(1.2 \times 10^{-6})}}{2}$$

$$= \frac{-3.3 \times 10^{-4} \pm 2.2 \times 10^{-3}}{2}$$

Structural formula of aspirin (acetylsalicylic acid), a well-known headache remedy. Note the acidic hydrogen atom (in color).

**Figure 16.4** ▶  
The structure of aspirin

Electrostatic potential map of aspirin.

(continued)

**Example 16.3** (continued)

Exercise 16.3 mentions that pyruvic acid is formed in biological cells. In muscle tissue, glucose is broken down to pyruvic acid, which is eventually oxidized to carbon dioxide and water. The structural formula of pyruvic acid is

and the electrostatic potential map is

If you take the lower sign in  $\pm$ , you will get a negative value for  $x$ . But  $x$  equals the concentration of  $\text{H}_3\text{O}^+$  ion, so it must be positive. Therefore, you ignore the negative solution. Taking the upper sign, you get

$$x = [\text{H}_3\text{O}^+] = 9.4 \times 10^{-4}$$

Now you can calculate the pH.

$$\text{pH} = -\log [\text{H}_3\text{O}^+] = -\log(9.4 \times 10^{-4}) = \mathbf{3.03}$$

**Answer Check** As in the previous example, you can do a quick check of your work by essentially reversing the problem, calculating  $K_a$  from the equilibrium concentrations of acid, conjugate base, and hydronium ion. You can obtain this from the last line of the equilibrium table, now that you have the value of  $x$ .

$$[\text{HAcs}] = 0.0036 - x = 0.0036 - 9.4 \times 10^{-4} = 0.0027$$

$$[\text{Acs}^-] = [\text{H}_3\text{O}^+] = x = 9.4 \times 10^{-4}$$

Substituting these values into the expression for  $K_a$  gives the value of the equilibrium constant.

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{Acs}^-]}{[\text{HAcs}]} = \frac{(9.4 \times 10^{-4})^2}{0.0027} = 3.3 \times 10^{-4}$$

**Exercise 16.3** What is the pH of an aqueous solution that is 0.0030  $M$  pyruvic acid,  $\text{HC}_3\text{H}_3\text{O}_3$ ? (Pyruvic acid forms during the breakdown of glucose in a cell.) ◀

See Problems 16.43 and 16.44.

**CONCEPT CHECK 16.1**

You have prepared dilute solutions of equal molar concentrations of  $\text{HC}_2\text{H}_3\text{O}_2$  (acetic acid),  $\text{HNO}_2$ ,  $\text{HF}$ , and  $\text{HCN}$ . Rank the solutions from the highest pH to the lowest pH. (Refer to Table 16.1.)

**16.2 Polyprotic Acids**

In the preceding section, we dealt only with acids releasing one  $\text{H}_3\text{O}^+$  ion or proton. Some acids, however, have two or more such protons; these acids are called *polyprotic acids*. Sulfuric acid, for example, can lose two protons in aqueous solution. One proton is lost completely to form  $\text{H}_3\text{O}^+$  (sulfuric acid is a strong acid).

The hydrogen sulfate ion,  $\text{HSO}_4^-$ , may then lose the other proton. In this case, an equilibrium exists.

For a weak diprotic acid like carbonic acid,  $\text{H}_2\text{CO}_3$ , there are two simultaneous equilibria to consider.

Carbonic acid is in equilibrium with the hydrogen carbonate ion,  $\text{HCO}_3^-$ , which is in turn equilibrated with the carbonate ion,  $\text{CO}_3^{2-}$ . Each equilibrium has an associated acid-ionization constant. For the loss of the first proton,

$$K_{a1} = \frac{[\text{H}_3\text{O}^+][\text{HCO}_3^-]}{[\text{H}_2\text{CO}_3]} = 4.3 \times 10^{-7}$$

and for the loss of the second proton,

$$K_{a2} = \frac{[\text{H}_3\text{O}^+][\text{CO}_3^{2-}]}{[\text{HCO}_3^-]} = 4.8 \times 10^{-11}$$

Note that  $K_{a1}$  for carbonic acid is much larger than  $K_{a2}$  (by a factor of about  $1 \times 10^4$ ). This indicates that carbonic acid loses the first proton more easily than the second one, because the first proton separates from an ion of single negative charge, whereas the second proton separates from an ion of double negative charge. This double negative charge strongly attracts the proton back to it.

In general, the second ionization constant,  $K_{a2}$ , of a polyprotic acid is much smaller than the first ionization constant,  $K_{a1}$ . In the case of a triprotic acid, the third ionization constant,  $K_{a3}$ , is much smaller than the second one,  $K_{a2}$ .

For example, see the values for phosphoric acid,  $\text{H}_3\text{PO}_4$ , in Table 16.1.

Calculating the concentrations of various species in a solution of a polyprotic acid might appear complicated, because several equilibria occur at once. However, reasonable assumptions can be made that simplify the calculation, as we show in the next example.

### Example 16.4 Calculating Concentrations of Species in a Solution of a Diprotic Acid

#### Gaining Mastery Toolbox

##### Critical Concept 16.4

For many polyprotic acids, the first ionization constant,  $K_{a1}$ , can be used to calculate the pH of the solution. Typically, the first ionization constant of a polyprotic acid is much greater than the subsequent ionization constant(s). Therefore, it is the first ionization step of the acid that creates the bulk of the  $\text{H}_3\text{O}^+(aq)$  in solution.

##### Solution Essentials:

- Polyprotic acid
- Acid ionization constant ( $K_a$ )
- pH
- Relative strengths of acids and bases
- Equilibrium-constant expression

Ascorbic acid (vitamin C) is a diprotic acid,  $\text{H}_2\text{C}_6\text{H}_6\text{O}_6$  (Figure 16.5). What is the pH of a 0.10 M solution? What is the concentration of ascorbate ion,  $\text{C}_6\text{H}_6\text{O}_6^{2-}$ ? The acid ionization constants are  $K_{a1} = 7.9 \times 10^{-5}$  and  $K_{a2} = 1.6 \times 10^{-12}$ .

**Problem Strategy** Diprotic acids have two ionization constants, one for the loss of each proton. To be exact, you should account for both reactions. However,  $K_{a2}$  is so much smaller than  $K_{a1}$  that the smaller amount of hydronium ion produced in the second reaction can be neglected. Follow the three steps for solving equilibrium problems.

Considering only the first ionization, set up a table of concentrations (starting, change, and equilibrium). Substitute these values into the equilibrium equation for  $K_{a1}$ , solve for  $x = [\text{H}_3\text{O}^+]$ , and then solve for pH (as in Example 16.2). Ascorbate ion is produced in the second ionization; its concentration, as we show, equals  $K_{a2}$ .

**Solution** **CALCULATION OF pH** Abbreviate the formula for ascorbic acid as  $\text{H}_2\text{Asc}$ . Hydronium ions are produced by two successive acid ionizations.

If you let  $x$  be the amount of  $\text{H}_3\text{O}^+$  formed in the first ionization, you get the following results:

<b>Concentration (M)</b>	<b><math>\text{H}_2\text{Asc}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{HAsc}^-(aq)</math></b>		
Starting	0.10	~0	0
Change	-x	+x	+x
Equilibrium	0.10 - x	x	x

*(continued)*

**Example 16.4** (continued)

Structural formula of ascorbic acid (vitamin C); note the acidic hydrogen atoms (in color).

Electrostatic potential map of ascorbic acid.

**Figure 16.5** ▲

The structure of ascorbic acid

Now substitute into the equilibrium-constant equation for the first ionization.

$$\frac{[\text{H}_3\text{O}^+][\text{HAsc}^-]}{[\text{H}_2\text{Asc}]} = K_{a1}$$

$$\frac{x^2}{0.10 - x} = 7.9 \times 10^{-5}$$

Assuming  $x$  to be much smaller than 0.10, you get

$$\frac{x^2}{0.10} \approx 7.9 \times 10^{-5}$$

or

$$x^2 \approx 7.9 \times 10^{-5} \times 0.10$$

$$x \approx 2.8 \times 10^{-3} = 0.0028$$

(Note that  $0.10 - x = 0.10 - 0.0028 = 0.10$ , correct to two significant figures. Therefore, the assumption that  $0.10 - x \approx 0.10$  is correct.)

The hydronium-ion concentration is 0.0028  $M$ , so

$$\text{pH} = -\log[\text{H}_3\text{O}^+] = -\log(0.0028) = \mathbf{2.55}$$

**ASCORBATE-ION CONCENTRATION** Ascorbate ion,  $\text{Asc}^{2-}$ , which we will call  $y$ , is produced only in the second reaction. Assume the starting concentrations of  $\text{H}_3\text{O}^+$  and  $\text{HAsc}^-$  for this reaction to be those from the first equilibrium. The amounts of the species in 1 L of solution are as follows:

Concentration (M)	$\text{HAsc}^-(\text{aq})$	$\text{H}_2\text{O}(\text{l})$	$\rightleftharpoons$	$\text{H}_3\text{O}^+(\text{aq})$	$+$	$\text{Asc}^{2-}(\text{aq})$
Starting	0.0028			0.0028		0
Change	$-y$			$+y$		$+y$
Equilibrium	$0.0028 - y$			$0.0028 + y$		$y$

Now substitute into the equilibrium-constant equation for the second ionization.

$$\frac{[\text{H}_3\text{O}^+][\text{Asc}^{2-}]}{[\text{HAsc}^-]} = K_{a2}$$

$$\frac{(0.0028 + y)y}{0.0028 - y} = 1.6 \times 10^{-12}$$

This equation can be simplified if you assume that  $y$  is much smaller than 0.0028. (Again, this assumes that the reaction occurs to only a small extent, as you expect from the magnitude of the equilibrium constant.) That is,

$$0.0028 + y \approx 0.0028$$

$$0.0028 - y \approx 0.0028$$

Then the equilibrium equation reads

$$\frac{(0.0028)y}{0.0028} \approx 1.6 \times 10^{-12}$$

Hence,

$$y \approx 1.6 \times 10^{-12}$$

(Note that  $1.6 \times 10^{-12}$  is indeed much smaller than 0.0028, as you assumed.)

The concentration of ascorbate ion equals  $K_{a2}$ , or  $\mathbf{1.6 \times 10^{-12} M}$ .

**Answer Check** Because the second ionization constant of an acid,  $K_{a2}$ , is always smaller than the first ionization constant,  $K_{a1}$ , you should expect any species produced during the second ionization to be in lower concentration than those from the first ionization.

A CHEMIST Looks at . . .

## Acid Rain

### Environment

*Acid rain* means rain having a pH lower than that of natural rain (pH 5.6). Natural rain dissolves carbon dioxide from the atmosphere to give a slightly acidic solution. The pH of rain in eastern North America and western Europe, however, is approximately 4 and sometimes lower. This acidity is primarily the result of the dissolving in rainwater of sulfur oxides and nitrogen oxides from human activities. In the northeastern United States, the strong acid components in acid rain are about 62% sulfuric acid, 32% nitric acid, and 6% hydrochloric acid.

The sulfuric acid in acid rain has been traced to the burning of fossil fuels and to the burning of sulfide ores in the production of metals, such as zinc and copper. Coal, for example, contains some sulfur mainly as pyrite, or iron(II) disulfide,  $\text{FeS}_2$ . When this burns in air, it produces sulfur dioxide.

In the presence of dust particles and other substances in polluted air, the sulfur dioxide oxidizes further to give sulfur trioxide, which reacts with water to form sulfuric acid.

Almost all of the sulfuric acid dissociates into the ions  $\text{H}_3\text{O}^+$ ,  $\text{HSO}_4^-$ , and  $\text{SO}_4^{2-}$ . The first ionization of  $\text{H}_2\text{SO}_4$  is complete; the second ionization (that of  $\text{HSO}_4^-$ ) is partial ( $K_{a2} = 1.1 \times 10^{-2}$ ).

Acid rain can be harmful to some plants, to fish (by changing the pH of lake water), and to structural materials and monuments (Figure 16.6). Marble, for example, is composed of calcium carbonate,  $\text{CaCO}_3$ , which dissolves in water of low pH.

It is instructive to calculate the pH of natural rain—that is, water saturated with carbon dioxide from the atmosphere. For this, you need to solve two equilibrium problems. First, you need the equilibrium for the solution of  $\text{CO}_2$  in water.

$$K = \frac{[\text{H}_2\text{CO}_3]}{P_{\text{CO}_2}} = 3.5 \times 10^{-2}$$

Here  $[\text{H}_2\text{CO}_3]$  represents the concentration of the molecular species formed when  $\text{CO}_2$  dissolves in water. The partial pressure of  $\text{CO}_2$  in the atmosphere is 0.00033 atm. If you substitute this for  $P_{\text{CO}_2}$  and solve for  $[\text{H}_2\text{CO}_3]$ , you obtain  $1.2 \times 10^{-5} M$ . (Note that the equilibrium-constant equation involving  $P_{\text{CO}_2}$  is essentially Henry's law, discussed in Section 12.3.) Now you need to account for the acid ionization of  $\text{H}_2\text{CO}_3$ . Following the general rule for polyprotic acids that  $K_{a2}$  is much smaller than  $K_{a1}$ , you look

(continued)

### Example 16.4 (continued)

**Exercise 16.4** Sulfurous acid,  $\text{H}_2\text{SO}_3$ , is a diprotic acid with  $K_{a1} = 1.3 \times 10^{-2}$  and  $K_{a2} = 6.3 \times 10^{-8}$ . The acid forms when sulfur dioxide (a gas with a suffocating odor) dissolves in water. What is the pH of a 0.25 M solution of sulfurous acid? What is the concentration of sulfite ion,  $\text{SO}_3^{2-}$ , in the solution? Note that  $K_{a1}$  is relatively large.

See Problems 16.47 and 16.48.

Example 16.4 shows that  $[\text{H}_3\text{O}^+]$  and  $[\text{HA}^-]$  in a solution of a diprotic acid  $\text{H}_2\text{A}$  can be calculated from the first ionization constant,  $K_{a1}$ .

The concentration of the ion  $\text{A}^{2-}$  equals the second ionization constant,  $K_{a2}$ .

## A CHEMIST Looks at . . . Acid Rain (continued)

Richard Megna/Fundamental Photographs

Kristen Brochmann/Fundamental Photographs

**Figure 16.6** ▲

**Effect of acid rain on marble** These photographs of a marble statue of George Washington, located in New York, were taken 60 years apart. The more recent photograph (*right*) shows that much of the detail of the statue has been dissolved by acid rain. Marble ( $\text{CaCO}_3$ ) reacts with  $\text{H}_3\text{O}^+$  ion to form soluble  $\text{Ca}(\text{HCO}_3)_2$ .

only at the first ionization, which produces almost all of the  $\text{H}_3\text{O}^+$ .

$$K_{a1} = \frac{[\text{H}_3\text{O}^+][\text{HCO}_3^-]}{[\text{H}_2\text{CO}_3]} = 4.3 \times 10^{-7}$$

Denoting  $[\text{H}_3\text{O}^+] = [\text{HCO}_3^-]$  by  $x$ , you can write the equilibrium equation

$$\frac{x^2}{1.2 \times 10^{-5} - x} = 4.3 \times 10^{-7}$$

Making the usual assumption about neglecting  $x$  in the denominator, you obtain  $x = [\text{H}_3\text{O}^+] = 2.3 \times 10^{-6}$ . This assumption and the neglect of the self-ionization of water affect the answer in the second significant figure. Retaining one significant figure,  $\text{pH} = -\log(2 \times 10^{-6}) = 5.7$ , which is essentially what we gave earlier for the pH of natural rain.

■ See Problems 16.133 and 16.134.

## 16.3 Base-Ionization Equilibria

Equilibria involving weak bases are treated similarly to those for weak acids. Ammonia, for example, ionizes in water as follows:

The corresponding equilibrium constant is

$$K_c = \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3][\text{H}_2\text{O}]}$$

Because the concentration of pure  $\text{H}_2\text{O}$  is constant, you can rearrange this equation as you did for acid ionization. ►

$$K_b = [\text{H}_2\text{O}]K_c = \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]}$$

In general, a weak base **B** with the *base ionization*

In terms of the thermodynamic equilibrium constant, the activity of  $\text{H}_2\text{O}$  is 1, so it does not appear explicitly in the equilibrium constant.

**Table 16.2** Base-Ionization Constants at 25°C

Substance	Formula	$K_b$
Ammonia	$\text{NH}_3$	$1.8 \times 10^{-5}$
Aniline	$\text{C}_6\text{H}_5\text{NH}_2$	$4.2 \times 10^{-10}$
Dimethylamine	$(\text{CH}_3)_2\text{NH}$	$5.1 \times 10^{-4}$
Ethylamine	$\text{C}_2\text{H}_5\text{NH}_2$	$4.7 \times 10^{-4}$
Hydrazine	$\text{N}_2\text{H}_4$	$1.7 \times 10^{-6}$
Hydroxylamine	$\text{NH}_2\text{OH}$	$1.1 \times 10^{-8}$
Methylamine	$\text{CH}_3\text{NH}_2$	$4.4 \times 10^{-4}$
Pyridine	$\text{C}_5\text{H}_5\text{N}$	$1.4 \times 10^{-9}$
Urea	$\text{NH}_2\text{CONH}_2$	$1.5 \times 10^{-14}$

has a **base-ionization constant**,  $K_b$  (the equilibrium constant for the ionization of a weak base), equal to

$$K_b = \frac{[\text{HB}^+][\text{OH}^-]}{[\text{B}]}$$

Table 16.2 lists ionization constants for some weak bases. All of these bases are similar to ammonia in that they have a N atom with a lone pair of electrons that accepts an  $\text{H}^+$  ion from water. For example, the base ionization of methylamine,  $\text{CH}_3\text{NH}_2$ , is

© Cengage Learning

**Figure 16.7** ▲

**Many over-the-counter drugs are salts of bases** These salts are often chlorides (frequently called hydrochlorides) and are analogous to ammonium chloride. You might find it instructive to read the ingredients from the labels for these products.

Many drugs and plant substances such as caffeine are bases. Often a prescription or over-the-counter drug is a salt of a base, because the salt is more soluble in water (Figure 16.7). These salts are analogous to the salts of ammonia, such as  $\text{NH}_4\text{Cl}$ . Other common bases are anions of weak acids. Examples are  $\text{F}^-$  and  $\text{C}_2\text{H}_3\text{O}_2^-$  (acetate ion). We will discuss these in the next section.

In the following exercise, you will determine the  $K_b$  of a molecular base from the pH of a solution. For these calculations, you can check to see if a simplifying assumption is valid by making sure that the concentration of base  $C_b$  divided by the  $K_b$  equals 100 or more. Note that this is essentially the problem you looked at in Example 16.1.

Some other well-known alkaloids and their plant sources are nicotine (tobacco), cocaine (coca bush), mescaline (species of cactus), and caffeine (coffee and tea).

**Exercise 16.5** Quinine is an alkaloid, or naturally occurring base, used to treat malaria. A 0.0015  $M$  solution of quinine has a pH of 9.84. The basicity of alkaloids is due to a nitrogen atom that picks up protons from water in the same manner as ammonia does. ◀ What is  $K_b$ ?

See Problems 16.51 and 16.52.

### Example 16.5 Calculating Concentrations of Species in a Weak Base Solution Using $K_b$

#### Gaining Mastery Toolbox

##### Critical Concept 16.5

Calculation of the species in a solution of a weak base are performed in the

Morphine,  $\text{C}_{17}\text{H}_{19}\text{NO}_3$ , is administered medically to relieve pain. It is a naturally occurring base, or alkaloid. What is the pH of a 0.0075  $M$  solution of morphine at 25°C? The base-ionization constant,  $K_b$ , is  $1.6 \times 10^{-6}$  at 25°C.

(continued)

**Example 16.5** (continued)

same manner as for a weak acid. For a weak base, the ionization constant is  $K_b$ , and the chemical reaction is written as the base ionizing in water.

**Solution Essentials:**

- Base ionization constant ( $K_b$ )
- pH
- Self-ionization of water ( $K_w = [\text{H}_3\text{O}^+][\text{OH}^-]$ )
- Relative strengths of acids and bases
- Equilibrium-constant expression

**Problem Strategy** First of all, you need to be aware that the compound  $\text{C}_{17}\text{H}_{19}\text{NO}_3$  is a weak base. The calculation for the ionization of a weak base parallels that used with weak acids in Examples 16.2 and 16.3: you write the equation, make a table of concentrations (Step 1), set up the equilibrium-constant equation for  $K_b$  (Step 2), and solve for  $x = [\text{OH}^-]$  (Step 3). Because  $C_b(0.0075)$  divided by  $K_b (1.5 \times 10^{-6})$  is greater than 100, the self-ionization of water can be neglected. You obtain  $[\text{H}_3\text{O}^+]$ , and then the pH, by solving  $K_w = [\text{H}_3\text{O}^+][\text{OH}^-]$ .

**Solution** Morphine, which we abbreviate as Mor, ionizes by picking up a proton from water (as does ammonia).

**Step 1:** Summarize the concentrations in a table. For the *change* values, note that the morphine in 1 L of solution ionizes to give  $x$  mol  $\text{HMor}^+$  and  $x$  mol  $\text{OH}^-$ .

Concentration (M)	$\text{Mor}(aq)$	$+$	$\text{H}_2\text{O}(l)$	$\rightleftharpoons$	$\text{HMor}^+(aq)$	$+$	$\text{OH}^-(aq)$
Starting	0.0075				0		$\sim 0$
Change	$-x$				$+x$		$+x$
Equilibrium	$0.0075 - x$				$x$		$x$

**Step 2:** Substituting into the equilibrium equation

$$\frac{[\text{HMor}^+][\text{OH}^-]}{[\text{Mor}]} = K_b$$

gives

$$\frac{x^2}{0.0075 - x} = 1.6 \times 10^{-6}$$

**Step 3:** Because  $C_b/K_b$  is greater than 100, we can assume that  $x$  is small enough to neglect compared with 0.0075, you have

$$0.0075 - x \approx 0.0075$$

and you can write the equilibrium-constant equation as

$$\frac{x^2}{0.0075} \approx 1.6 \times 10^{-6}$$

Hence,

$$x^2 \approx 1.6 \times 10^{-6} \times 0.0075 = 1.2 \times 10^{-8}$$

$$x = [\text{OH}^-] \approx 1.1 \times 10^{-4}$$

You can now calculate the hydronium-ion concentration. The product of the hydronium-ion concentration and the hydroxide-ion concentration equals  $1.0 \times 10^{-14}$  at  $25^\circ\text{C}$ :

$$[\text{H}_3\text{O}^+][\text{OH}^-] = 1.0 \times 10^{-14}$$

Substituting into this equation gives

$$[\text{H}_3\text{O}^+] \times 1.1 \times 10^{-4} = 1.0 \times 10^{-14}$$

Hence,

$$[\text{H}_3\text{O}^+] = \frac{1.0 \times 10^{-14}}{1.1 \times 10^{-4}} = 9.1 \times 10^{-11}$$

The pH of the solution is

$$\text{pH} = -\log [\text{H}_3\text{O}^+] = -\log(9.1 \times 10^{-11}) = \mathbf{10.04}$$

Note that you could also calculate the pH using the formula  $\text{pH} + \text{pOH} = 14.00$ . You would first calculate the pOH; then  $\text{pH} = 14.00 - \text{pOH}$ .

(continued)

**Example 16.5** (continued)

**Answer Check** A reasonable answer for the pH of a weak base in aqueous solution is greater than 7.

**Exercise 16.6** What is the hydronium-ion concentration of a 0.20 M solution of ammonia in water? See Table 16.2 for  $K_b$ .

See Problems 16.53 and 16.54.

 **CONCEPT CHECK 16.2**

A base B is placed into a beaker of water with the result depicted below (water molecules have been omitted for clarity). Write the ionization reaction for this base and classify the base as being strong or weak.

**Figure 16.8** ▲

**Salt solutions are acidic, neutral, or basic** A pH meter measures the pH of solutions of the salts  $\text{NH}_4\text{Cl}$ ,  $\text{NaCl}$ , and  $\text{Na}_2\text{CO}_3$ .

## 16.4 Acid–Base Properties of Salt Solutions

A salt may be regarded as an ionic compound obtained by a neutralization reaction in aqueous solution. The resulting salt solution may be neutral, but often it is acidic or basic (Figure 16.8). One of the successes of the Brønsted–Lowry concept of acids and bases was in pointing out that some ions can act as acids or bases. The acidity or basicity of a salt solution is explained in terms of the acidity or basicity of individual ions in the solution.

Consider a solution of sodium cyanide,  $\text{NaCN}$ . A 0.1 M solution has a pH of 11.1 and is therefore fairly basic. Sodium cyanide dissolves in water to give  $\text{Na}^+$  and  $\text{CN}^-$  ions.

Sodium ion,  $\text{Na}^+$ , is unreactive with water, but the cyanide ion,  $\text{CN}^-$ , reacts to produce  $\text{HCN}$  and  $\text{OH}^-$ .

From the Brønsted–Lowry point of view, the  $\text{CN}^-$  ion acts as a base, because it accepts a proton from  $\text{H}_2\text{O}$ . You can also see, however, that  $\text{OH}^-$  ion is a product, so you expect the solution to have a basic pH. This explains why solutions of  $\text{NaCN}$  are basic.

The reaction of the  $\text{CN}^-$  ion with water is referred to as the *hydrolysis* of  $\text{CN}^-$ . The **hydrolysis** of an ion is the reaction of an ion with water to produce the conjugate acid and hydroxide ion or the conjugate base and hydronium ion. The  $\text{CN}^-$  ion hydrolyzes to give the conjugate acid and  $\text{OH}^-$  ion. As another example, consider the ammonium ion,  $\text{NH}_4^+$ , which hydrolyzes as follows:

The ammonium ion acts as an acid, donating a proton to  $\text{H}_2\text{O}$  and forming  $\text{NH}_3$ . Note that this equation has the form of an acid ionization, so you could write the  $K_a$  expression for it. Similarly, the hydrolysis reaction for the  $\text{CN}^-$  ion has the form of a base ionization, so you could write the  $K_b$  expression for it.

Two questions become apparent. First, how can you predict whether a particular salt solution will be acidic, basic, or neutral? Then, how can you calculate the concentrations of  $\text{H}_3\text{O}^+$  ion and  $\text{OH}^-$  ion in the salt solution (or, equivalently, how do you predict the pH of the salt solution)? We will now look at the first of these questions.

### Prediction of Whether a Salt Solution Is Acidic, Basic, or Neutral

When the  $\text{CN}^-$  ion hydrolyzes, it produces the conjugate acid, HCN. Hydrogen cyanide, HCN, is a weak acid. That means that it tends to hold on to the proton strongly (does not ionize readily). In other words, the cyanide ion,  $\text{CN}^-$ , tends to pick up a proton easily, so it acts as a base. This argument can be generalized: *The anions of weak acids are basic. On the other hand, the anions of strong acids have hardly any basic character; that is, these ions do not hydrolyze.* For example, the  $\text{Cl}^-$  ion, which is conjugate to the strong acid HCl, shows no appreciable reaction with water.

Now consider a cation conjugate to a weak base. The simplest example is the  $\text{NH}_4^+$  ion, which we just discussed. It behaves like an acid. *The cations of weak bases are acidic. On the other hand, the cations of strong bases (metal ions of Groups 1A and 2A elements—except Be) have hardly any acidic character; that is, these ions do not hydrolyze.* For example,

Aqueous metal ions, other than the cations of the strong bases, usually hydrolyze by acting as acids. These ions usually form hydrated metal ions. For example, the aluminum ion  $\text{Al}^{3+}$  forms the hydrated ion  $\text{Al}(\text{H}_2\text{O})_6^{3+}$ . The bare  $\text{Al}^{3+}$  ion acts as a Lewis acid, forming bonds to the electron pairs on O atoms of  $\text{H}_2\text{O}$  molecules. Because the electrons are drawn away from the O atoms by the Al atom, the O atoms in turn tend to draw electrons from the O—H bonds, making them highly polar. As a result, the  $\text{H}_2\text{O}$  molecules in  $\text{Al}(\text{H}_2\text{O})_6^{3+}$  are acidic. The  $\text{Al}(\text{H}_2\text{O})_6^{3+}$  ion hydrolyzes in aqueous solution by donating a proton (from one of the acidic  $\text{H}_2\text{O}$  molecules on the ion) to water molecules in the solvent. After the proton leaves the hydrated metal ion, the ion charge is reduced by 1 and one  $\text{H}_2\text{O}$  molecule on the ion becomes a hydroxide ion bonded to the metal. Thus, the formula of the ion becomes  $\text{Al}(\text{H}_2\text{O})_5(\text{OH})^{2+}$ .

To predict the acidity or basicity of a salt solution, you need to examine the acidity or basicity of the ions composing the salt. Consider potassium acetate,  $\text{KC}_2\text{H}_3\text{O}_2$ . The ions are  $\text{K}^+$  and  $\text{C}_2\text{H}_3\text{O}_2^-$  (acetate ion). Potassium is a Group 1A element, so  $\text{K}^+$  does not hydrolyze. However, the acetate ion is the conjugate of acetic acid, a weak acid. Therefore, the acetate ion is basic.

A solution of potassium acetate is predicted to be basic.

From this discussion, we can derive a set of rules for deciding whether a salt solution will be neutral, acidic, or basic. These rules apply to normal salts (those in which the anion has no acidic hydrogen atoms).

1. **A salt of a strong base and a strong acid.** The salt has no hydrolyzable ions and so gives a neutral aqueous solution. An example is NaCl.

2. **A salt of a strong base and a weak acid.** The anion of the salt is the conjugate of the weak acid. It hydrolyzes to give a basic solution. An example is NaCN.

3. **A salt of a weak base and a strong acid.** The cation of the salt is the conjugate of the weak base. It hydrolyzes to give an acidic solution. An example is  $\text{NH}_4\text{Cl}$ .

4. **A salt of a weak base and a weak acid.** Both ions hydrolyze. Whether the solution is acidic or basic depends on the relative acid–base strengths of the two ions. To determine this, you need to compare the  $K_a$  of the cation with the  $K_b$  of the anion. If the  $K_a$  is larger, the solution is acidic. If the  $K_b$  is larger, the solution is basic. Consider solutions of ammonium formate,  $\text{NH}_4\text{CHO}_2$ . These solutions are slightly acidic, because the  $K_a$  for  $\text{NH}_4^+$  ( $= 5.6 \times 10^{-10}$ ) is somewhat larger than the  $K_b$  for formate ion,  $\text{CHO}_2^-$  ( $= 5.9 \times 10^{-11}$ ).

The next example illustrates the application of these rules.

### Example 16.6 Predicting Whether a Salt Solution Is Acidic, Basic, or Neutral

#### Gaining Mastery Toolbox

##### Critical Concept 16.6

Soluble salts dissolve in water to produce ions. Certain types of aqueous ions from dissolved salts react with water (hydrolyze) to produce  $\text{H}_3\text{O}^+(aq)$  or  $\text{OH}^-(aq)$ . When  $\text{H}_3\text{O}^+$  is produced, the solution becomes acidic. When  $\text{OH}^-$  is produced, the solution becomes basic. When the dissolved salt contains basic and acidic aqueous ions, equilibrium constants  $K_a$  and  $K_b$  must be used to determine if the solution is acidic or basic.

##### Solution Essentials:

- Rules for hydrolysis reactions of salts in solution
- Hydrolysis
- Base-ionization constant ( $K_b$ )
- Acid-ionization constant ( $K_a$ )
- Conjugate acid–base pair
- Relative strengths of acids and bases
- Soluble salt

Decide whether aqueous solutions of the following salts are acidic, basic, or neutral: a.  $\text{KCl}$ ; b.  $\text{NaF}$ ; c.  $\text{Zn}(\text{NO}_3)_2$ ; d.  $\text{NH}_4\text{CN}$ .

**Problem Strategy** Start by determining what type of acid–base reaction occurred to make the salt. Once you know this, you can apply the rules above to predict whether a solution will be acidic, basic, or neutral.

#### Solution

- a.  $\text{KCl}$  produces  $\text{K}^+(aq)$  and  $\text{Cl}^-(aq)$  ions in solution and is a salt of a strong base ( $\text{KOH}$ ) and a strong acid ( $\text{HCl}$ ), so none of the ions hydrolyze, and a solution of  $\text{KCl}$  is **neutral**.
- b.  $\text{NaF}$  produces  $\text{Na}^+(aq)$  and  $\text{F}^-(aq)$  in solution and is a salt of a strong base ( $\text{NaOH}$ ) and a weak acid ( $\text{HF}$ ), so a solution of  $\text{NaF}$  is **basic** because of the hydrolysis of  $\text{F}^-$ . (You can assume  $\text{HF}$  is a weak acid, because it is not one of the common strong acids listed in Table 15.1.)
- c.  $\text{Zn}(\text{NO}_3)_2$  produces  $\text{Zn}^{2+}(aq)$  and  $\text{NO}_3^-(aq)$  in solution and is the salt of a weak base ( $\text{Zn}(\text{OH})_2$ ) and a strong acid ( $\text{HNO}_3$ ), so a solution of  $\text{Zn}(\text{NO}_3)_2$  is **acidic**. Note also that  $\text{Zn}^{2+}$  is not an ion of a Group 1A or Group 2A element, so you can expect it to form a metal hydrate ion that hydrolyzes to give an acidic solution.
- d.  $\text{NH}_4\text{CN}$  produces  $\text{NH}_4^+(aq)$  and  $\text{CN}^-(aq)$  in solution and is a salt of a weak base ( $\text{NH}_3$ ) and a weak acid ( $\text{HCN}$ ). Therefore, to answer the question, you would need the  $K_a$  for  $\text{NH}_4^+$  and the  $K_b$  for  $\text{CN}^-$ . Although these are listed in some tables, more frequently they are not. However, as you will see later in this section, values are easily calculated from the molecular substances that are conjugates ( $\text{NH}_3$  and  $\text{HCN}$ ). The  $K_a$  for  $\text{NH}_4^+$  is  $5.6 \times 10^{-10}$ , and the  $K_b$  for  $\text{CN}^-$  is  $2.0 \times 10^{-5}$ . From these values, you conclude that a solution of  $\text{NH}_4\text{CN}$  is **basic**.

**Answer Check** You can check your answers by writing hydrolysis reactions for each of the ions in solution. If either or both of these reactions produce a weak acid or base, the solution will not be neutral. You then can analyze the products of these reactions for  $\text{OH}^-$  and/or  $\text{H}_3\text{O}^+$  to check your final answer (keep in mind you may have to look at the  $K_a$  and  $K_b$  information as well). For example, using  $\text{NaF}$  from part b, the hydrolysis reactions for the ions that make up this salt are

(continued)

**Example 16.6** (continued)

Because there was no reaction for the  $\text{Na}^+$ , and  $\text{OH}^-$  was produced by the hydrolysis of  $\text{F}^-$ , the solution containing the  $\text{NaF}$  salt is basic.

**Exercise 16.7** Consider solutions of the following salts: a.  $\text{NH}_4\text{NO}_3$ ; b.  $\text{KNO}_3$ ; c.  $\text{Al}(\text{NO}_3)_3$ . For each, state whether the solution is acidic, basic, or neutral.

See Problems 16.59 and 16.60.

**The pH of a Salt Solution**

Suppose you wish to calculate the pH of 0.10 M  $\text{NaCN}$ . As you have seen, the solution is basic because of the hydrolysis of the  $\text{CN}^-$  ion. The calculation is essentially the same as that for any weak base (Example 16.5). You would require the base-ionization constant of the cyanide ion. However, frequently the ionization constants for ions are not listed directly in tables, because the values are easily related to those for the conjugate molecular species. Thus, the  $K_b$  for  $\text{CN}^-$  is related to the  $K_a$  for  $\text{HCN}$ .

To see this relationship between  $K_a$  and  $K_b$  for conjugate acid–base pairs, consider the acid ionization of  $\text{HCN}$  and the base ionization of  $\text{CN}^-$ . When these two reactions are added, you get the ionization of water.

The equilibrium constants for the reactions are shown symbolically at the right. In Section 14.2, it was shown that when two reactions are added, their equilibrium constants are multiplied. Therefore, ►

$$K_a K_b = K_w$$

This relationship is general and shows that the product of acid- and base-ionization constants in aqueous solution for conjugate acid–base pairs equals the ion-product constant for water,  $K_w$ .

Another way to obtain this result is by multiplying the expression for  $K_b$  by  $[\text{H}_3\text{O}^+]/[\text{H}_3\text{O}^+]$  and rearranging.

$$\begin{aligned} K_b &= \frac{[\text{HCN}][\text{OH}^-]}{[\text{CN}^-]} \times \frac{[\text{H}_3\text{O}^+]}{[\text{H}_3\text{O}^+]} \\ &= \frac{[\text{H}_3\text{O}^+][\text{OH}^-]}{[\text{HCN}]} \end{aligned}$$

This is equivalent to

$$K_b = K_w/K_a \quad \text{or} \quad K_a K_b = K_w$$

**Example 16.7** Obtaining  $K_a$  from  $K_b$  or  $K_b$  from  $K_a$ **Gaining Mastery Toolbox****Critical Concept 16.7**

Acid- and base-ionization constants are related. The equation that relates  $K_a$  and  $K_b$  is  $K_a K_b = K_w$ .

**Solution Essentials:**

- Mathematical relationship between  $K_a$  and  $K_b$  ( $K_a K_b = K_w$ )
- Base-ionization constant ( $K_b$ )
- Acid-ionization constant ( $K_a$ )
- Ion-product constant for water ( $K_w = 1.0 \times 10^{-14}$ )
- Conjugate acid–base pair
- Equilibrium-constant expression

Use Tables 16.1 and 16.2 to obtain the following at 25°C: a.  $K_b$  for  $\text{CN}^-$ ; b.  $K_a$  for  $\text{NH}_4^+$ .

**Problem Strategy** Keeping in mind that  $K_w$  is known, we can apply the formula  $K_a K_b = K_w$  to find the unknown ionization constant ( $K_a$  or  $K_b$ ).

**Solution**

a. The conjugate acid of  $\text{CN}^-$  is  $\text{HCN}$ , whose  $K_a$  is  $4.9 \times 10^{-10}$  (Table 16.1). Hence,

$$K_b = \frac{K_w}{K_a} = \frac{1.0 \times 10^{-14}}{4.9 \times 10^{-10}} = 2.0 \times 10^{-5}$$

Note that  $K_b$  is approximately equal to  $K_b$  for ammonia ( $1.8 \times 10^{-5}$ ). This means that the base strength of  $\text{CN}^-$  is comparable to that of  $\text{NH}_3$ .

b. The conjugate base of  $\text{NH}_4^+$  is  $\text{NH}_3$ , whose  $K_b$  is  $1.8 \times 10^{-5}$  (Table 16.2). Hence,

$$K_a = \frac{K_w}{K_b} = \frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}} = 5.6 \times 10^{-10}$$

(continued)

**Example 16.7** (continued)

$\text{NH}_4^+$  is a relatively weak acid. Acetic acid, by way of comparison, has  $K_a$  equal to  $1.7 \times 10^{-5}$ .

**Answer Check** Be aware that the values of  $K_a$ ,  $K_b$ , and  $K_w$  are all temperature dependent, so make sure that you are using the appropriate values when performing calculations.

**Exercise 16.8** Calculate the following at 25°C, using Tables 16.1 and 16.2: a.  $K_b$  for  $\text{F}^-$ ; b.  $K_a$  for  $\text{C}_6\text{H}_5\text{NH}_3^+$  (conjugate acid of aniline,  $\text{C}_6\text{H}_5\text{NH}_2$ ).

See Problems 16.63 and 16.64.

For a solution of a salt in which only one of the ions hydrolyzes, the calculation of the concentrations of species present follows that for solutions of weak acids or bases. The only difference is that you must first obtain  $K_a$  or  $K_b$  for the ion that hydrolyzes. The next example illustrates the reasoning and calculations involved.

**Example 16.8** Calculating Concentrations of Species in a Salt Solution**Gaining Mastery Toolbox****Critical Concept 16.8**

When salts dissolve in solution, the aqueous anions may hydrolyze with water. Recognize the conjugates of weak acids and bases and be able to write the chemical equations for the hydrolysis reactions of these conjugates.

**Solution Essentials:**

- Rules for hydrolysis reactions of salts in solution
- Hydrolysis reaction
- Mathematical relationship between  $K_a$  and  $K_b$  ( $K_a K_b = K_w$ )
- Base-ionization constant ( $K_b$ )
- Acid-ionization constant ( $K_a$ )
- pH
- Ion-product constant for water ( $K_w = 1.0 \times 10^{-14}$ )
- Relative strengths of acids and bases
- Conjugate acid–base pair
- Equilibrium-constant expression

What is the pH of 0.10 M sodium nicotinate at 25°C (a problem posed in the chapter opening)? The  $K_a$  for nicotinic acid was determined in Example 16.1 to be  $1.4 \times 10^{-5}$  at 25°C.

**Problem Strategy** We first need to determine the relevant reactions of sodium nicotinate in water. If there is a reaction, we need to write it down and determine whether the reaction is that of an acid or of a base. If the reaction is that of an acid, we will need to use  $K_a$  in our calculations; for a base, we will need  $K_b$ . If necessary, we can use the equation  $K_a K_b = K_w$  to find the needed ionization constant. We then can perform the equilibrium calculation in the usual manner.

**Solution** Sodium nicotinate gives  $\text{Na}^+$  and nicotinate ions in solution. Only the nicotinate ion hydrolyzes. Write  $\text{HNic}$  for nicotinic acid and  $\text{Nic}^-$  for the nicotinate ion. The hydrolysis of nicotinate ion is

Nicotinate ion acts as a base, and you can calculate the concentration of species in solution as in Example 16.5. First, however, you need  $K_b$  for the nicotinate ion. This is related to  $K_a$  for nicotinic acid by the equation  $K_a K_b = K_w$ . Substituting, you get

$$K_b = \frac{K_w}{K_a} = \frac{1.0 \times 10^{-14}}{1.4 \times 10^{-5}} = 7.1 \times 10^{-10}$$

Now you can proceed with the equilibrium calculation. We will only sketch this calculation, because it is similar to that in Example 16.5. You let  $x = [\text{HNic}] = [\text{OH}^-]$  and then substitute into the equilibrium-constant equation.

$$\frac{[\text{HNic}][\text{OH}^-]}{[\text{Nic}^-]} = K_b$$

(continued)

**Example 16.8** (continued)

This gives

$$\frac{x^2}{0.10 - x} = 7.1 \times 10^{-10}$$

Solving this equation, you find that  $x = [\text{OH}^-] = 8.4 \times 10^{-6}$ . Hence,

$$\text{pH} = 14.00 - \text{pOH} = 14.00 + \log(8.4 \times 10^{-6}) = \mathbf{8.92}$$

**Answer Check** Use the rules for predicting whether a salt is acidic, basic, or neutral to assess your answer. In this case, the solution was prepared by dissolving the salt of a strong base and a weak acid, so we should expect the correct answer to have a pH greater than 7.

**Exercise 16.9** Benzoic acid,  $\text{HC}_7\text{H}_5\text{O}_2$ , and its salts are used as food preservatives. What is the concentration of benzoic acid in an aqueous solution of 0.015 M sodium benzoate? What is the pH of the solution?  $K_a$  for benzoic acid is  $6.3 \times 10^{-5}$ .

See Problems  
16.65, 16.66,  
16.67, and 16.68.

**CONCEPT CHECK 16.3**

Which of the following aqueous solutions has the highest pH and which has the lowest? **a** 0.1 M  $\text{NH}_3$ ; **b** 0.1 M  $\text{NH}_4\text{Br}$ ; **c** 0.1 M  $\text{NaF}$ ; **d** 0.1 M  $\text{NaCl}$ .

## ► Solutions of a Weak Acid or Base with Another Solute

In the preceding sections, we looked at solutions that contained a weak acid, a weak base, or a salt of a weak acid or base. In the remaining sections of this chapter, we will look at the effect of adding another solute to a solution of a weak acid or base. The solutes we will look at are those that significantly affect acid or base ionization—that is, strong acids and bases, and salts that contain an ion that is produced in the acid or base ionization. These solutes affect the equilibrium through the *common-ion effect*.

### 16.5 Common-Ion Effect

The **common-ion effect** is the shift in an ionic equilibrium caused by the addition of a solute that provides an ion that takes part in the equilibrium. Consider a solution of acetic acid,  $\text{HC}_2\text{H}_3\text{O}_2$ , in which you have the following acid-ionization equilibrium:

Suppose you add  $\text{HCl}(aq)$  to this solution. What is the effect on the acid-ionization equilibrium? Because  $\text{HCl}(aq)$  is a strong acid, it provides  $\text{H}_3\text{O}^+$  ion, which is present on the right side of the equation for acetic acid ionization. According to Le Châtelier's principle, the equilibrium composition should shift to the left. ►

The degree of ionization of acetic acid is decreased by the addition of a strong acid. This repression of the ionization of acetic acid by  $\text{HCl}(aq)$  is an example of the common-ion effect.

Le Châtelier's principle was applied in Section 14.7 to the problem of adding substances to an equilibrium mixture.

**CONCEPT CHECK 16.4**

The chemical equation for the hydrolysis of nitrous acid is

Which of the following, when added to a nitrous acid solution, would reduce the degree of ionization of the acid:  $\text{NaNO}_3(\text{aq})$ ,  $\text{KNO}_2(\text{aq})$ ,  $\text{HNO}_3(\text{aq})$ , or  $\text{NaCl}(\text{aq})$ ?

**Example 16.9 Calculating the Common-Ion Effect on Acid Ionization (Effect of a Strong Acid)****Gaining Mastery Toolbox****Critical Concept 16.9**

Chemical equilibrium will be shifted by the addition of an aqueous ion that is present in a chemical reaction (Le Châtelier's principle). The concentrations of all the aqueous reactants and products change when the equilibrium is shifted.

**Solution Essentials:**

- Common-ion effect
- Acid-ionization constant ( $K_a$ )
- Degree of ionization
- Relative strengths of acids and bases
- Le Châtelier's principle
- Equilibrium-constant expression

The degree of ionization of acetic acid,  $\text{HC}_2\text{H}_3\text{O}_2$ , in a 0.10 *M* aqueous solution at 25°C is 0.013.  $K_a$  at this temperature is  $1.7 \times 10^{-5}$ . Calculate the degree of ionization of  $\text{HC}_2\text{H}_3\text{O}_2$  in a 0.10 *M* solution at 25°C to which sufficient HCl is added to make it 0.010 *M* HCl. How is the degree of ionization affected?

**Problem Strategy** This is an acid-ionization problem, but it differs from the simple ionization illustrated by Example 16.2. Here you have a starting concentration of  $\text{H}_3\text{O}^+$  (= 0.010 *M*) from the addition of a strong acid (HCl). This gives a different type of equation in Step 2, but you solve it in Step 3 by using a similar approximation method. You assume that  $x$  is small compared with starting concentrations of acid and  $\text{H}_3\text{O}^+$ , so that the resulting equation is linear, rather than quadratic. The calculation of degree of ionization follows that in Example 16.2. Note that the degree of ionization given in the problem (0.013) refers to the 0.10 *M*  $\text{HC}_2\text{H}_3\text{O}_2$  solution prior to the addition of the HCl. Therefore, this information is not used in solving the problem but is used for comparison with the calculated answer.

**Solution**

**Step 1:** Starting concentrations are  $[\text{HC}_2\text{H}_3\text{O}_2] = 0.10 \text{ M}$ ,  $[\text{H}_3\text{O}^+] = 0.010 \text{ M}$  (from HCl), and  $[\text{C}_2\text{H}_3\text{O}_2^-] = 0$ . The acetic acid ionizes to give an additional  $x$  mol/L of  $\text{H}_3\text{O}^+$  and  $x$  mol/L of  $\text{C}_2\text{H}_3\text{O}_2^-$ . The table is

Concentration (M)	$\text{HC}_2\text{H}_3\text{O}_2(\text{aq})$	$+$	$\text{H}_2\text{O}(\text{l})$	$\rightleftharpoons$	$\text{H}_3\text{O}^+(\text{aq})$	$+$	$\text{C}_2\text{H}_3\text{O}_2^-(\text{aq})$
Starting	0.10				0.010		0
Change	$-x$				$+x$		$+x$
Equilibrium	$0.10 - x$				$0.010 + x$		$x$

**Step 2:** You substitute into the equilibrium-constant equation

$$\frac{[\text{H}_3\text{O}^+][\text{C}_2\text{H}_3\text{O}_2^-]}{[\text{HC}_2\text{H}_3\text{O}_2]} = K_a$$

obtaining

$$\frac{(0.010 + x)x}{0.10 - x} = 1.7 \times 10^{-5}$$

**Step 3:** To solve this equation, assume that  $x$  is small compared with 0.010. Then

$$0.010 + x \approx 0.010$$

$$0.10 - x \approx 0.10$$

The equation becomes

$$\frac{0.010x}{0.10} \approx 1.7 \times 10^{-5}$$

Solving for  $x$ , you get

$$x = 1.7 \times 10^{-5} \times \frac{0.10}{0.010} = 1.7 \times 10^{-4}$$

(continued)

**Example 16.9** (continued)

The degree of ionization of  $\text{HC}_2\text{H}_3\text{O}_2$  is  $x/0.10 = \mathbf{0.0017}$ . This is much smaller than the value for  $0.10\text{ M HC}_2\text{H}_3\text{O}_2$  (0.013), because **the addition of HCl suppresses the ionization of  $\text{HC}_2\text{H}_3\text{O}_2$ .**

**Answer Check** As with all problems of this type, check to see that all approximations made are valid. In this case, make certain that  $x$  can be neglected in the  $0.010 + x$  terms.

**Exercise 16.10** What is the concentration of formate ion,  $\text{CHO}_2^-$ , in a solution at  $25^\circ\text{C}$  that is  $0.10\text{ M HCHO}_2$  and  $0.20\text{ M HCl}$ ? What is the degree of ionization of formic acid,  $\text{HCHO}_2$ ?

See Problems 16.69 and 16.70.

As you will see in the following section, solutions that contain a weak acid or a weak base and a corresponding salt are especially important. Therefore, you will need to be able to calculate the concentrations of species present in such solutions. A solution of acetic acid and sodium acetate is an example. From Le Châtelier's principle, you can see that the addition of acetate ion (from sodium acetate) suppresses the ionization of the acetic acid by the common-ion effect:

The next example illustrates the calculation of pH, which is similar to that of the previous example.

**Example 16.10** Calculating the Common-Ion Effect on Acid Ionization (Effect of a Conjugate Base)**Gaining Mastery Toolbox****Critical Concept 16.10**

Before performing calculations, the relevant hydrolysis reaction for the acid or base must be determined. When you add a soluble salt to a solution containing an acid or base, you must determine if there is an ion (a common ion) that will affect the chemical reaction.

**Solution Essentials:**

- Common-ion effect
- Acid ionization constant ( $K_a$ )
- pH
- Le Châtelier's principle
- Equilibrium-constant expression

A solution is prepared to be  $0.10\text{ M}$  acetic acid,  $\text{HC}_2\text{H}_3\text{O}_2$ , and  $0.20\text{ M}$  sodium acetate,  $\text{NaC}_2\text{H}_3\text{O}_2$ . What is the pH of this solution at  $25^\circ\text{C}$ ?  $K_a$  for acetic acid at  $25^\circ\text{C}$  is  $1.7 \times 10^{-5}$ .

**Problem Strategy** First you need to identify the relevant reaction for the acid or base in solution. In this case,

Once you have the reaction, you need to see whether there are any ions in solution from the added salt ( $\text{NaC}_2\text{H}_3\text{O}_2$ ) that will affect the chemical reaction (a common ion). If there is a common ion, as there is here ( $\text{C}_2\text{H}_3\text{O}_2^-$ ), you need to take into account its concentration when creating your table and performing calculations.

**Solution**

**Step 1:** Consider the equilibrium

Initially, 1 L of solution contains 0.10 mol of acetic acid. Sodium acetate is a strong electrolyte, so 1 L of solution contains 0.20 mol of acetate ion (a common ion). When the acetic acid ionizes, it gives  $x$  mol of hydronium ion and  $x$  mol of acetate ion. This is summarized in the following table:

Concentration (M)	$\text{HC}_2\text{H}_3\text{O}_2(\text{aq})$	$+$	$\text{H}_2\text{O}(\text{l})$	$\rightleftharpoons$	$\text{H}_3\text{O}^+(\text{aq})$	$+$	$\text{C}_2\text{H}_3\text{O}_2^-(\text{aq})$
Starting	0.10				$\sim 0$		0.20
Change	$-x$				$+x$		$+x$
Equilibrium	$0.10 - x$				$x$		$0.20 + x$

(continued)

**Example 16.10** (continued)

**Step 2:** The equilibrium-constant equation is

$$\frac{[\text{H}_3\text{O}^+][\text{C}_2\text{H}_3\text{O}_2^-]}{[\text{HC}_2\text{H}_3\text{O}_2]} = K_a$$

Substituting into this equation gives

$$\frac{x(0.20 + x)}{0.10 - x} = 1.7 \times 10^{-5}$$

**Step 3:** To solve the equation, assume that  $x$  is small compared with 0.10 and 0.20. Then

$$0.20 + x \approx 0.20$$

$$0.10 - x \approx 0.10$$

The equilibrium equation becomes

$$\frac{x(0.20)}{0.10} \approx 1.7 \times 10^{-5}$$

Hence,

$$x \approx 1.7 \times 10^{-5} \times \frac{0.10}{0.20} = 8.5 \times 10^{-6}$$

(Note that  $x$  is indeed much smaller than 0.10 or 0.20.) The hydronium-ion concentration is  $8.5 \times 10^{-6} M$ , and

$$\text{pH} = -\log [\text{H}_3\text{O}^+] = -\log(8.5 \times 10^{-6}) = \mathbf{5.07}$$

For comparison, the pH of 0.10  $M$  acetic acid is 2.88.

**Answer Check** Always make sure that the ions in solution will have an effect on the equilibrium. For example, if the solution were 0.20  $M$  NaCl instead of 0.20  $M$   $\text{HC}_2\text{H}_3\text{O}_2$ , there would have been no common ion, and therefore the calculated pH would be the same as that of a solution of only 0.20  $M$   $\text{HC}_2\text{H}_3\text{O}_2$ .

**Exercise 16.11** One liter of solution was prepared by dissolving 0.025 mol of formic acid,  $\text{HCHO}_2$ , and 0.018 mol of sodium formate,  $\text{NaCHO}_2$ , in water. What was the pH of the solution?  $K_a$  for formic acid is  $1.7 \times 10^{-4}$ .

See Problems 16.71 and 16.72.

The previous examples considered the common-ion effect in solutions of weak acids. You also encounter the common-ion effect in solutions of weak bases. For example, the base ionization of  $\text{NH}_3$  is

This suggests that you could suppress, or decrease the effect of, the base ionization by adding an ammonium salt (providing  $\text{NH}_4^+$  ion) or a strong base (providing  $\text{OH}^-$  ion). The calculations are similar to those for acid ionization, except that you use the appropriate base ionization.

## 16.6 Buffers

A **buffer** is a solution characterized by the ability to resist changes in pH when limited amounts of acid or base are added to it. If 0.01 mol of hydrochloric acid is added to 1 L of pure water, the pH changes from 7.0 to 2.0—a pH change of 5.0 units. By contrast, the addition of this amount of hydrochloric acid to 1 L of buffered solution might change the pH by only 0.1 unit. Biological fluids, such as blood, are usually

buffer solutions; the control of pH is vital to proper functioning of these fluids. The oxygen-carrying function of blood depends on its being maintained very near a pH of 7.4. If the pH were to change by a tenth of a unit, the capacity of the blood to carry oxygen would be lost.

Buffers contain either a weak acid and its conjugate base or a weak base and its conjugate acid. Thus, a buffer solution contains both an acid species and a base species in equilibrium. To understand the action of a buffer, consider one that contains approximately equal molar amounts of a weak acid HA and its conjugate base  $A^-$ . When a strong acid is added to the buffer, it supplies hydronium ions that react with the base  $A^-$ .

On the other hand, when a strong base is added to the buffer, it supplies hydroxide ions. These react with the acid HA.

A buffer solution resists changes in pH through its ability to combine with both  $H_3O^+$  and  $OH^-$  ions. Figure 16.9 depicts this buffer action.

Blood, as a buffer solution, contains  $H_2CO_3$  and  $HCO_3^-$ , as well as other conjugate acid–base pairs. A buffer frequently used in the laboratory contains varying proportions of the conjugate acid–base pair  $H_2PO_4^-$  and  $HPO_4^{2-}$  (Figure 16.10).

Buffers also have commercial applications. For example, the label on a package of artificial fruit juice mix says that it contains “citric acid to provide tartness (acidity) and sodium citrate to regulate tartness.” A solution of citric acid and its conjugate base, citrate ion (provided by sodium citrate), functions as an acid–base buffer, which is what “to regulate tartness” means. The pH of the buffer is in the acid range.

Two important characteristics of a buffer are its pH and its *buffer capacity*, which is the amount of acid or base the buffer can react with before giving a significant pH change. Buffer capacity depends on the amount of acid and conjugate base in the solution. Figure 16.11 illustrates the change in pH of a buffer solution containing 1.0 mol of acetic acid and 1.0 mol of acetate ion to which varying amounts of  $H_3O^+$  and  $OH^-$  are added. This buffer changes less than 0.5 pH unit as long as no more than 0.5 mol  $H_3O^+$  or  $OH^-$  ion is added. Note that this is one-half (or less than one-half) the amounts of acid and conjugate base in the solution. The ratio of amount of acid to amount of conjugate base is also important. Unless this ratio is close to 1 (between 1:10 and 10:1), the buffer capacity will be too low to be useful.

The other important characteristic of a buffer is its pH. Let us now look at how to calculate the pH of a buffer.

**Figure 16.9** ▲

**Buffer action** A buffer is a solution of about equal molar amounts of a weak acid, HA, and its conjugate base,  $A^-$ , in equilibrium (center beaker). When an acid, such as HCl, is added to the buffer,  $H_3O^+$  from this acid reacts with  $A^-$  in the buffer to produce HA (left beaker). However, when a base, such as NaOH, is added to the buffer,  $OH^-$  from this base reacts with HA in the buffer to produce  $A^-$  (right beaker). The buffer pH changes only slightly in both cases.

**Figure 16.10** ▲

**Some laboratory buffers** These commercially prepared buffer solutions have different proportions of the same conjugate acid and base.

**Figure 16.11** ▶

**Effect of added acid or base on a buffer solution** The buffer contains 1.0 mol of acetic acid and 1.0 mol of acetate ion in 1.00 L of solution. Note that the addition of 0.5 mol or less of strong acid or base gives only a small change of pH.

### The pH of a Buffer

The solution described in Example 16.10 is a buffer, because it is a solution of a weak acid (0.10 *M* acetic acid) and its conjugate base (0.20 *M* acetate ion from sodium acetate). The example described how to calculate the pH of such a buffer (we obtained a pH of 5.07). The next example is similar, except now you are given a recipe for making up a buffer from volumes of solutions and are asked to calculate the pH. In this example, the buffer consists of a molecular base ( $\text{NH}_3$ ) and its conjugate acid ( $\text{NH}_4^+$ ).

### Example 16.11 Calculating the pH of a Buffer from Given Volumes of Solution

#### Gaining Mastery Toolbox

##### Critical Concept 16.11

Buffer solutions can be prepared by mixing an acid and the conjugate base of the acid or a base and the conjugate acid of the base. A buffer solution, regardless of the way it is prepared, will resist pH changes when limited amounts of acid or base are added to the solution because it contains a conjugate acid–base pair.

##### Solution Essentials:

- Buffer
- Base-ionization constant ( $K_b$ )
- Acid-ionization constant ( $K_a$ )
- pH
- Conjugate acid–base pair
- Relative strengths of acids and bases
- Equilibrium-constant expression

Instructions for making up a buffer say to mix 60. mL (0.060 L) of 0.100 *M*  $\text{NH}_3$  with 40. mL (0.040 L) of 0.100 *M*  $\text{NH}_4\text{Cl}$ . What is the pH of this buffer?

**Problem Strategy** The buffer contains a base and its conjugate acid in equilibrium. The equation is

The problem is to obtain the concentration of  $\text{H}_3\text{O}^+$  or  $\text{OH}^-$  in this equilibrium mixture. To do the equilibrium calculation, you need the starting concentrations in the solution obtained by mixing the  $\text{NH}_3$  and  $\text{NH}_4\text{Cl}$  solutions. For this, you calculate the moles of  $\text{NH}_3$  and moles of  $\text{NH}_4^+$  added to the buffer solution, and divide by the total volume of buffer. Then you are ready to do the equilibrium calculation.

**Solution** How many moles of  $\text{NH}_3$  are added? Recall that

$$\text{Molarity } \text{NH}_3 = \frac{\text{moles } \text{NH}_3}{\text{liters } \text{NH}_3 \text{ solution}}$$

Note that the instructions say to add 60. mL (or 0.060 L) of 0.100 *M*  $\text{NH}_3$ . So

$$\text{Moles } \text{NH}_3 = \text{molarity } \text{NH}_3 \times \text{liters } \text{NH}_3 \text{ solution}$$

$$= 0.100 \frac{\text{mol}}{\text{L}} \times 0.060 \text{ L} = 0.0060 \text{ mol } \text{NH}_3$$

In the same way, you find that you have added 0.0040 mol  $\text{NH}_4^+$  (from  $\text{NH}_4\text{Cl}$ ). Assume that the total volume of buffer equals the sum of the volumes of the two solutions.

$$\text{Total volume buffer} = 60. \text{ mL} + 40. \text{ mL} = 100. \text{ mL} (0.100 \text{ L})$$

(continued)

**Example 16.11** (continued)

Therefore, the concentrations of base and conjugate acid are

$$[\text{NH}_3] = \frac{0.0060 \text{ mol}}{0.100 \text{ L}} = 0.060 \text{ M}$$

$$[\text{NH}_4^+] = \frac{0.0040 \text{ mol}}{0.100 \text{ L}} = 0.040 \text{ M}$$

**Step 1:** Fill in the concentration table for the acid–base equilibrium (base ionization of  $\text{NH}_3$ ).

Concentration (M)	$\text{NH}_3(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{NH}_4^+(\text{aq}) + \text{OH}^-(\text{aq})$
Starting	0.060                      0.040                      0
Change	− $x$ + $x$ + $x$
Equilibrium	0.060 − $x$ 0.040 + $x$ $x$

**Step 2:** You substitute the equilibrium concentrations into the equilibrium-constant equation.

$$\frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]} = K_b$$

$$\frac{(0.040 + x)x}{0.060 - x} = 1.8 \times 10^{-5}$$

**Step 3:** To solve this equation, you assume that  $x$  is small compared with 0.040 and 0.060. So this equation becomes

$$\frac{0.040x}{0.060} = 1.8 \times 10^{-5}$$

Therefore,  $x = (0.060/0.040) \times (1.8 \times 10^{-5}) = 2.7 \times 10^{-5}$ . (Check that  $x$  can be neglected in  $0.040 + x$  and  $0.060 - x$ .) Thus, the hydroxide-ion concentration is  $2.7 \times 10^{-5} \text{ M}$ . The pH of the buffer is

$$\text{pH} = 14.00 - \text{pOH} = 14.00 + \log(2.7 \times 10^{-5}) = \mathbf{9.43}$$

(If you have  $2.7 \times 10^{-5}$  in your calculator from the previous calculation, you obtain the pH by pressing the *log* button, then adding 14.)

**Answer Check** To avoid a very common mistake, prior to setting up the equilibrium problem, always make sure that you first take into account the total volume of solution and then calculate the concentrations.

**Exercise 16.12** What is the pH of a buffer prepared by adding 30.0 mL of 0.15 M  $\text{HC}_2\text{H}_3\text{O}_2$  (acetic acid) to 70.0 mL of 0.20 M  $\text{NaC}_2\text{H}_3\text{O}_2$  (sodium acetate)?

See Problems 16.75 and 16.76.

### Adding an Acid or a Base to a Buffer

We noted earlier that a buffer resists changes in pH, and we also described qualitatively how this occurs. What we want to do here is to show quantitatively that a buffer does indeed tend to resist pH change when a small quantity of an acid or a base is added to it.

All of the previous acid–base examples dealt with situations in which an acid and its conjugate base were close to equilibrium. In the following example, we consider the addition of a strong acid to an acetic acid/acetate ion buffer. Hydronium ion reacts with the conjugate base (acetate ion) in the buffer, so that the concentrations of species in solution change markedly from their initial value. (If you add a strong base to this buffer, hydroxide ion reacts with acetic acid in the buffer.)

**Example 16.12** Calculating the pH of a Buffer When a Strong Acid or Strong Base Is Added**Gaining Mastery Toolbox****Critical Concept 16.12**

Strong acids react completely with weak bases, and strong bases react completely with weak acids. When either a strong acid or strong base is added to a buffer, a stoichiometric calculation is performed prior to the equilibrium calculation. The result of the stoichiometric calculation is the starting point for the equilibrium calculation.

**Solution Essentials:**

- Buffer
- Base-ionization constant ( $K_b$ )
- Acid-ionization constant ( $K_a$ )
- pH
- Relative strengths of acids and bases
- Equilibrium-constant expression
- Volumetric analysis

Calculate the pH of 75 mL of the buffer solution described in Example 16.10 (0.10  $M$   $\text{HC}_2\text{H}_3\text{O}_2$  and 0.20  $M$   $\text{NaC}_2\text{H}_3\text{O}_2$ ) to which 9.5 mL of 0.10  $M$  hydrochloric acid is added. Compare the pH change with what would occur if this amount of acid were added to pure water.

**Problem Strategy** Do the problem in two parts. To get started, you assume that the  $\text{H}_3\text{O}^+$  ion from the strong acid and the conjugate base from the buffer react completely. This is a stoichiometric calculation. Next, you need to refine the assumption from the stoichiometric calculation that you started with, because in reality the  $\text{H}_3\text{O}^+$  ion and the base from the buffer reach equilibrium just before complete reaction. So you now solve the equilibrium problem using concentrations from the stoichiometric calculation. Because these concentrations are not far from equilibrium, you can use the usual simplifying assumption about  $x$ .

**Solution** When hydronium ion (from hydrochloric acid) is added to the buffer, it reacts with acetate ion.

Because acetic acid is a weak acid, you can assume as a first approximation that the reaction goes to completion. This part of the problem is simply a stoichiometric calculation. Then you assume that the acetic acid ionizes slightly. This part of the problem involves an acid-ionization equilibrium.

**STOICHIOMETRIC CALCULATION** You must first calculate the amounts of hydrogen ion, acetate ion, and acetic acid present in the solution before reaction. The molar amount of hydrogen ion will equal the molar amount of hydrochloric acid added, which you obtain by converting the volume of hydrochloric acid, HCl, to moles of HCl. To do this, you note for 0.10  $M$  HCl that 1 L HCl is equivalent to 0.10 mol HCl. Hence, to convert 9.5 mL ( $9.5 \times 10^{-3}$  L) of hydrochloric acid, you have

$$9.5 \times 10^{-3} \text{ L HCl} \times \frac{0.10 \text{ mol HCl}}{1 \text{ L HCl}} = 0.00095 \text{ mol HCl}$$

Hydrochloric acid is a strong acid, so it exists in solution as the ions  $\text{H}_3\text{O}^+$  and  $\text{Cl}^-$ . Therefore, the amount of  $\text{H}_3\text{O}^+$  added is 0.00095 mol.

The amounts of acetate ion and acetic acid in the 75-mL sample are found in a similar way. The buffer in Example 16.10 contains 0.20 mol of acetate ion and 0.10 mol of acetic acid in 1 L of solution. The amounts in 75 mL (= 0.075 L) of solution are obtained by converting to moles.

$$0.075 \text{ L soln} \times \frac{0.20 \text{ mol C}_2\text{H}_3\text{O}_2^-}{1 \text{ L soln}} = 0.015 \text{ mol C}_2\text{H}_3\text{O}_2^-$$

$$0.075 \text{ L soln} \times \frac{0.10 \text{ mol HC}_2\text{H}_3\text{O}_2}{1 \text{ L soln}} = 0.0075 \text{ mol HC}_2\text{H}_3\text{O}_2$$

You now assume that all of the hydronium ion added (0.00095 mol) reacts with acetate ion. Therefore, 0.00095 mol of acetic acid is produced and 0.00095 mol of acetate ion is used up. Hence, after reaction you have

$$\text{Moles of acetate ion} = (0.015 - 0.00095) \text{ mol C}_2\text{H}_3\text{O}_2^- = 0.014 \text{ mol C}_2\text{H}_3\text{O}_2^-$$

$$\text{Moles of acetic acid} = (0.0075 + 0.00095) \text{ mol HC}_2\text{H}_3\text{O}_2 = 0.0085 \text{ mol HC}_2\text{H}_3\text{O}_2$$

**EQUILIBRIUM CALCULATION** You first calculate the concentrations of  $\text{HC}_2\text{H}_3\text{O}_2$  and  $\text{C}_2\text{H}_3\text{O}_2^-$  present in the solution before you consider the acid-ionization equilibrium. Note that the total volume of solution (buffer plus hydrochloric acid) is 75 mL + 9.5 mL, or 85 mL (0.085 L). Hence, the starting concentrations are

$$[\text{HC}_2\text{H}_3\text{O}_2] = \frac{0.0085 \text{ mol}}{0.085 \text{ L}} = 0.10 \text{ M}$$

(continued)

**Example 16.12** (continued)

$$[\text{C}_2\text{H}_3\text{O}_2^-] = \frac{0.014 \text{ mol}}{0.085 \text{ L}} = 0.16 \text{ M}$$

From this, you construct the following table:

Concentration (M)	$\text{HC}_2\text{H}_3\text{O}_2(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{H}_3\text{O}^+(\text{aq}) + \text{C}_2\text{H}_3\text{O}_2^-(\text{aq})$		
Starting	0.10	~0	0.16
Change	-x	+x	+x
Equilibrium	0.10 - x	x	0.16 + x

The equilibrium-constant equation is

$$\frac{[\text{H}_3\text{O}^+][\text{C}_2\text{H}_3\text{O}_2^-]}{[\text{HC}_2\text{H}_3\text{O}_2]} = K_a$$

Substituting, you get

$$\frac{x(0.16 + x)}{0.10 - x} = 1.7 \times 10^{-5}$$

If you assume that  $x$  is small enough that  $0.16 + x \approx 0.16$  and  $0.10 - x \approx 0.10$ , this equation becomes

$$\frac{x(0.16)}{0.10} = 1.7 \times 10^{-5}$$

or

$$x = 1.7 \times 10^{-5} \times \frac{0.10}{0.16} = 1.1 \times 10^{-5}$$

Note that  $x$  is indeed small, so the assumptions you made earlier are correct. The  $\text{H}_3\text{O}^+$  concentration is  $1.1 \times 10^{-5} \text{ M}$ . The pH is

$$\text{pH} = -\log [\text{H}_3\text{O}^+] = -\log(1.1 \times 10^{-5}) = 4.96$$

Because the pH of the buffer was 5.07 (see Example 16.10), the pH has changed by  $5.07 - 4.96 = 0.11$  unit.

**ADDING HCL TO PURE WATER** If 9.5 mL of 0.10 M hydrochloric acid were added to 75 mL of pure water, the hydronium-ion concentration would change to

$$[\text{H}_3\text{O}^+] = \frac{\text{amount of } \text{H}_3\text{O}^+ \text{ added}}{\text{total volume of solution}}$$

$$[\text{H}_3\text{O}^+] = \frac{0.00095 \text{ mol } \text{H}_3\text{O}^+}{0.085 \text{ L solution}} = 0.011 \text{ M}$$

(The total volume is 75 mL of water plus 9.5 mL HCl, assuming no change of volume on mixing.) The pH is

$$\text{pH} = -\log [\text{H}_3\text{O}^+] = -\log(0.011) = 1.96$$

**The pH of pure water is 7.00, so the change in pH is  $7.00 - 1.96 = 5.04$  units, compared with 0.11 unit for the buffered solution.**

**Answer Check** Generally speaking, buffer solutions will not undergo large changes in pH by the addition of small amounts of a strong acid or strong base, so this is something to look for in your answers. However, if the buffer capacity of the solution is exceeded, you will see significant changes in pH.

**Exercise 16.13** Suppose you add 50.0 mL of 0.10 M sodium hydroxide to 1 L of the solution described in Exercise 16.11. What would be the pH of the result?

See Problems 16.77 and 16.78.

### Henderson–Hasselbalch Equation

How do you prepare a buffer of given pH? We can show that the buffer must be prepared from a conjugate acid–base pair in which the acid-ionization constant is approximately equal to the desired  $\text{H}_3\text{O}^+$  concentration. To illustrate, consider a buffer made up of a weak acid HA and its conjugate base  $\text{A}^-$ . The acid-ionization equilibrium is

and the acid-ionization constant is

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]}$$

By rearranging, you get an equation for the  $\text{H}_3\text{O}^+$  concentration.

$$[\text{H}_3\text{O}^+] = K_a \times \frac{[\text{HA}]}{[\text{A}^-]}$$

This equation expresses the  $\text{H}_3\text{O}^+$  concentration in terms of the  $K_a$  for the acid and the ratio of concentrations of HA and  $\text{A}^-$ . This equation was derived from the equilibrium constant, so the concentrations of HA and  $\text{A}^-$  should be equilibrium values. But because the presence of  $\text{A}^-$  suppresses the ionization of HA, these concentrations do not differ significantly from the values used to prepare the buffer. If [HA] and  $[\text{A}^-]$  are approximately equal, the hydronium-ion concentration of the buffer is approximately equal to  $K_a$ .

You can use the preceding equation to derive an equation for the pH of a buffer. Take the negative logarithm of both sides of the equation. That is,

$$-\log[\text{H}_3\text{O}^+] = -\log\left(K_a \times \frac{[\text{HA}]}{[\text{A}^-]}\right) = -\log K_a - \log \frac{[\text{HA}]}{[\text{A}^-]}$$

The left side equals the pH. You can also simplify the right side. The  $\text{p}K_a$  of a weak acid is defined in a manner similar to pH and pOH. ◀

$$\text{p}K_a = -\log K_a$$

The previous equation can be written

$$\text{pH} = \text{p}K_a - \log \frac{[\text{HA}]}{[\text{A}^-]} = \text{p}K_a + \log \frac{[\text{A}^-]}{[\text{HA}]}$$

More generally, you can write

$$\text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]}$$

This is an equation relating the pH of a buffer for different concentrations of conjugate acid and base; it is known as the **Henderson–Hasselbalch equation**. By substituting the value of  $\text{p}K_a$  for the conjugate acid and the ratio [base]/[acid], you obtain the pH of the buffer.

The question we asked earlier was how to prepare a buffer of a given pH—for example, pH 4.90. You can see that you need to find a conjugate acid–base pair in which the  $\text{p}K_a$  of the acid is close to the desired pH.  $K_a$  for acetic acid is  $1.7 \times 10^{-5}$ , and its  $\text{p}K_a$  is  $-\log(1.7 \times 10^{-5}) = 4.77$ . You can get a pH somewhat higher by increasing the ratio [base]/[acid].

Consider the calculation of the pH of a buffer containing 0.10 M  $\text{NH}_3$  and 0.20 M  $\text{NH}_4\text{Cl}$ . The conjugate acid is  $\text{NH}_4^+$ , whose  $K_a$  you can calculate from  $K_b$  for  $\text{NH}_3$  ( $= 1.8 \times 10^{-5}$ ).  $K_a$  for  $\text{NH}_4^+$  is  $5.6 \times 10^{-10}$ , and the  $\text{p}K_a$  is  $-\log(5.6 \times 10^{-10}) = 9.25$ . Hence,

$$\text{pH} = 9.25 + \log \frac{0.10}{0.20} = 8.95$$

Acid- and base-ionization constants are often listed as  $\text{p}K_a$ s and  $\text{p}K_b$ s ( $\text{p}K_b = -\log K_b$ ).

The solution is basic, as you could have guessed, because the buffer contains the weak base  $\text{NH}_3$  and the very weak acid  $\text{NH}_4^+$ .

### CONCEPT CHECK 16.5

You add 1.5 mL of 1 M HCl to each of the following solutions. Which one will show the least change of pH?

- a 15 mL of 0.1 M NaOH
- b 15 mL of 0.1 M  $\text{HC}_2\text{H}_3\text{O}_2$
- c 30 mL of 0.1 M NaOH and 30 mL of 0.1 M  $\text{HC}_2\text{H}_3\text{O}_2$
- d 30 mL of 0.1 M NaOH and 60 mL of 0.1 M  $\text{HC}_2\text{H}_3\text{O}_2$

### CONCEPT CHECK 16.6

The beaker on the left below represents a buffer solution of a weak acid HA and its conjugate base,  $\text{A}^-$ . (Water molecules and spectator ions have been omitted for clarity.)

- a Which beaker on the right, X or Y, depicts the solution after the addition of two formula units of NaOH?
- b How many HCl molecules can be added to the original buffer solution before the buffer capacity is exceeded?
- c Draw a picture of the solution where the buffer capacity has been exceeded by the addition of HCl.

## 16.7 Acid–Base Titration Curves

An acid–base titration is a procedure for determining the amount of acid (or base) in a solution by determining the volume of base (or acid) of known concentration that will completely react with it. ► An **acid–base titration curve** is a plot of the pH of a solution of acid (or base) against the volume of added base (or acid). Such curves are used to gain insight into the titration process. You can use the titration curve to choose an indicator that will show when the titration is complete.

The technique of titration was discussed in Section 4.10.

### Titration of a Strong Acid by a Strong Base

Figure 16.12 shows a curve for the titration of 25.0 mL of 0.100 M HCl by 0.100 M NaOH. Note that the pH changes slowly at first until the molar amount of base added nearly equals that of the acid—that is, until the titration is near the equivalence point. The **equivalence point** is the point in a titration when a stoichiometric amount of reactant has been added. At the equivalence point, the pH of this solution of NaOH and HCl is 7.0, because it contains a salt, NaCl, that does not hydrolyze. However, the pH changes rapidly near the equivalence point, from a pH of about 3 to a pH of about 11. To detect the equivalence point, you add an indicator that changes color within the pH range 3–11. Phenolphthalein can be used, because it

**Figure 16.12** ▲

**Curve for the titration of a strong acid by a strong base** Here 25.0 mL of 0.100 *M* HCl is titrated by 0.100 *M* NaOH. The portions of the curve where indicators bromocresol green and phenolphthalein change color are shown. Note that both indicators change color where the pH changes rapidly (the nearly vertical part of the curve).

changes from colorless to pink in the pH range 8.2–10.0. (Figure 15.10 showed the pH ranges for the color changes of indicators.) Even though this color change occurs on the basic side, only a fraction of a drop of base is required to change the pH several units when the titration is near the equivalence point. The indicator bromocresol green, whose color changes in the pH range 3.8–5.4, would also work. Because the pH change is so large, many other indicators could be used.

The following example shows how to calculate a point on the titration curve of a strong acid and a strong base.

### Example 16.13 Calculating the pH of a Solution of a Strong Acid and a Strong Base

#### Gaining Mastery Toolbox

##### Critical Concept 16.13

Strong acids react completely with strong bases. Calculations involving reactions of strong acids and strong bases are stoichiometric (non-equilibrium).

##### Solution Essentials:

- pH
- Relative strengths of acids and bases
- Volumetric analysis

Calculate the pH of a solution in which 10.0 mL of 0.100 *M* NaOH is added to 25.0 mL of 0.100 *M* HCl.

**Problem Strategy** Whenever we are performing calculations that involve titrations, we need to write down the balanced chemical equation and determine the extent of the reaction. In this case, the reaction is between a strong acid and strong base, so we assume that the reaction is complete. Therefore, we will be performing a stoichiometric calculation.

**Solution** The equation is

You get the amounts of reactants by multiplying the volume (in liters) of each solution by its molar concentration.

$$\text{Mol H}_3\text{O}^+ = 0.0250 \text{ L} \times 0.100 \text{ mol/L} = 0.00250 \text{ mol}$$

$$\text{Mol OH}^- = 0.0100 \text{ L} \times 0.100 \text{ mol/L} = 0.00100 \text{ mol}$$

All of the  $\text{OH}^-$  reacts, leaving an excess of  $\text{H}_3\text{O}^+$ .

$$\text{Excess H}_3\text{O}^+ = (0.00250 - 0.00100) \text{ mol} = 0.00150 \text{ mol H}_3\text{O}^+$$

(continued)

**Example 16.13** (continued)

You obtain the concentration of  $\text{H}_3\text{O}^+$  by dividing this amount of  $\text{H}_3\text{O}^+$  by the total volume of solution ( $= 0.0250 \text{ L} + 0.0100 \text{ L} = 0.0350 \text{ L}$ ).

$$[\text{H}_3\text{O}^+] = \frac{0.00150 \text{ mol}}{0.0350 \text{ L}} = 0.0429$$

Hence,

$$\text{pH} = -\log [\text{H}_3\text{O}^+] = -\log(0.0429) = \mathbf{1.368}$$

**Answer Check** A quick check of the concentrations and volumes of the HCl and NaOH being reacted indicates that we would expect the answer to have a pH less than 7.

**Exercise 16.14** What is the pH of a solution in which 15 mL of 0.10 M NaOH has been added to 25 mL of 0.10 M HCl?

See Problems 16.85 and 16.86.

**Titration of a Weak Acid by a Strong Base**

The titration of a weak acid by a strong base gives a somewhat different curve. Figure 16.13 shows the curve for the titration of 25.0 mL of 0.100 M nicotinic acid,  $\text{HC}_6\text{H}_4\text{NO}_2$ , by 0.100 M NaOH. The titration starts at a higher pH than the titration of HCl, because nicotinic acid is a weak acid. As before, the pH changes slowly at first, then rapidly near the equivalence point. The pH range in which the rapid change is seen occurs from about pH 7 to pH 11. Note that the pH range is shorter than that for the titration of a strong acid by a strong base. This means that the choice of an indicator is more critical. Phenolphthalein would work; it changes color in the range

**Figure 16.13** ▲

**Curve for the titration of a weak acid by a strong base** Here 25.0 mL of 0.100 M nicotinic acid, a weak acid, is titrated by 0.100 M NaOH. Note that bromocresol green changes color during the early part of the titration, well before the equivalence point. Phenolphthalein changes color where the pH changes rapidly (near the equivalence point). Thus, phenolphthalein could be used as an indicator for the titration, whereas bromocresol green could not.

8.2–10.0. Bromcresol green would not work because it changes color in the range 3.8–5.4, which occurs before the titration curve rises steeply.

Note also that the equivalence point for the titration curve of nicotinic acid occurs on the basic side. This happens because at the equivalence point the solution is that of the salt, sodium nicotinate, which is basic from the hydrolysis of the nicotinate ion. The optimum choice of indicator would be one that changes color over a range that includes the pH of the equivalence point.

The following example shows how to calculate the pH at the equivalence point in the titration of a weak acid and a strong base.

### Example 16.14 Calculating the pH at the Equivalence Point in the Titration of a Weak Acid by a Strong Base

#### Gaining Mastery Toolbox

##### Critical Concept 16.14

A strong base will react completely with a weak acid. When a strong base is added to a solution containing a weak acid, a stoichiometric calculation is performed prior to the equilibrium calculation.

##### Solution Essentials:

- Acid–base titration
- Base-ionization constant ( $K_b$ )
- pH
- Relative strengths of acids and bases

Calculate the pH of the solution at the equivalence point when 25 mL of 0.10  $M$  nicotinic acid is titrated by 0.10  $M$  sodium hydroxide.  $K_a$  for nicotinic acid equals  $1.4 \times 10^{-5}$ .

**Problem Strategy** Because the titration is at the equivalence point, we know that equal molar amounts of nicotinic acid and sodium hydroxide have been reacted. From the chemical reaction we can determine that 1 mol of nicotinic acid reacts with 1 mol of sodium hydroxide to produce 1 mol of sodium nicotinate and 1 mol of water. We now can perform the stoichiometric calculation to determine the moles of nicotinate ion. Using this quantity and the total volume of solution, we can calculate the nicotinate ion concentration. We then can find the pH of this solution by treating it as a hydrolysis problem.

**Solution CONCENTRATION OF NICOTINATE ION:** Because the reaction is at the equivalence point, we assume that the reaction of the base with the acid is complete. The chemical equation for the titration is

Therefore, the calculation of the moles of nicotinate ion is

$$2.5 \times 10^{-3} \text{ L HNic} \times \frac{0.10 \text{ mol HNic}}{1 \text{ L HNic}} \times \frac{1 \text{ mol NaNic}}{1 \text{ mol HNic}} \times \frac{1 \text{ mol Nic}^-}{1 \text{ mol NaNic}} = 2.5 \times 10^{-4} \text{ mol Nic}^-$$

From the reaction stoichiometry, we know that 25 mL of 0.10  $M$  sodium hydroxide is needed to completely react with 25 mL of 0.10  $M$  nicotinic acid, so the total volume of solution is 50 mL (assuming there is no volume change on mixing). Dividing the molar amount of nicotinate ion by the volume of solution in liters gives the molar concentration of nicotinate ion.

$$\text{Molar concentration} = \frac{2.5 \times 10^{-4} \text{ mol}}{50 \times 10^{-3} \text{ L}} = 0.050 \text{ M}$$

**HYDROLYSIS OF NICOTINATE ION** This portion of the calculation follows the method given in Example 16.8. You find that  $K_b$  for nicotinate ion is  $7.1 \times 10^{-10}$  and that the concentration of hydroxide ion is  $6.0 \times 10^{-6} \text{ M}$ . The pH is **8.78**.

**Answer Check** One bad assumption that is often made concerning acid–base titrations is that the pH is always 7 at the equivalence point. Although this is true when strong acids and bases are used, it is not the case here. Note that you can predict whether the solution will be acidic or basic at the equivalence point by examining the products of the chemical reaction to see if an acid or base was produced. Here, the weak base  $\text{Nic}^-$  was produced; therefore, we would expect a correct answer to be a pH greater than 7.

**Exercise 16.15** What is the pH at the equivalence point when 25 mL of 0.10  $M$  HF is titrated by 0.15  $M$  NaOH?

See Problems 16.87 and 16.88.

**Figure 16.14** ▲

**Curve for the titration of a weak base by a strong acid** Here 25.0 mL of 0.100  $M$   $\text{NH}_3$  is titrated by 0.100  $M$   $\text{HCl}$ . Methyl red can be used as an indicator for the titration.

### Titration of a Weak Base by a Strong Acid

When you titrate a weak base by a strong acid, you get a titration curve similar to that obtained when a weak acid is titrated by a strong base. Figure 16.14 shows the pH changes during the titration of 25.0 mL of 0.100  $M$   $\text{NH}_3$  by 0.100  $M$   $\text{HCl}$ . In this case, the pH declines slowly at first, then falls abruptly from about pH 7 to pH 3. Methyl red, which changes color from yellow at pH 6.0 to red at pH 4.8, is a possible indicator for this titration. Note that phenolphthalein could not be used to find the equivalence point.

This last section covering acid–base titrations is an ideal place to illustrate how titration problems can be configured to encompass many of the ideas and problem-solving approaches encountered in this chapter. Although Example 16.15 is focused on the titration of a weak base by a strong acid, the concepts and operational skills apply to the other types of acid–base titrations.

#### Example 16.15 Calculation of the pH of a Solution at Several Points of a Titration of a Weak Base by a Strong Acid

##### Gaining Mastery Toolbox

##### Critical Concept 16.15

A weak base will react completely with a strong acid. When a strong acid is added to a solution containing a weak base, a stoichiometric calculation is performed prior to the equilibrium calculation.

Figure 16.14 is the curve for the titration of a 25-mL sample of 0.100  $M$   $\text{NH}_3$  by 0.100  $M$   $\text{HCl}$ . Calculate the pH of the  $\text{NH}_3$  solution at the following points during the titration: a. Prior to the addition of any  $\text{HCl}$ . b. After the addition of 12 mL of 0.100  $M$   $\text{HCl}$ . c. At the equivalence point. d. After the addition of 31 mL of 0.100  $M$   $\text{HCl}$ .

**Problem Strategy** The key to solving this problem is to relate each part to a problem that you have already encountered. Part a involves a weak base ( $\text{NH}_3$ ) in water, which was done in Example 16.5. For Part b, you need to recognize that all of the  $\text{H}_3\text{O}^+$  from the strong acid ( $\text{HCl}$ ) will completely react with the  $\text{NH}_3$ , creating a buffer

(continued)

**Example 16.15** (continued)**Solution Essentials:**

- Acid–base titration
- Buffer
- Acid-ionization constant ( $K_a$ )
- Base-ionization constant ( $K_b$ )
- pH
- Relative strengths of acids and bases
- Equilibrium-constant expression

solution. This is similar to Example 16.12. Part c is at the equivalence point, so you know that the moles of HCl added to the solution are equal to the moles of  $\text{NH}_3$ . As in Example 16.14, you will need to perform a stoichiometry problem followed by an equilibrium calculation, only this time it is for a weak base with a strong acid. Finally, in Part d, the titration is past the equivalence point. Because you are adding a strong acid beyond the equivalence point, the pH of the solution can be calculated based *only* on the moles of unreacted HCl ( $\text{H}_3\text{O}^+$ ) that remain in the solution.

**Solution**

a.  $\text{NH}_3$ , a weak base, undergoes the hydrolysis reaction

Starting with the initial concentration of  $\text{NH}_3$  of 0.100 *M*, you perform an equilibrium calculation by setting up a table and solving for the concentration of  $\text{OH}^-$ . Then calculate the pH.

The pH prior to the start of the titration is **11.13**.

b. When HCl is added to the  $\text{NH}_3$  solution, it undergoes the reaction

During the reaction all of the added HCl is consumed. (When looking at the reaction, keep in mind that because HCl is a strong acid, we represent it as  $\text{H}_3\text{O}^+$  in aqueous solution.) Solving this stoichiometry problem, you can determine the moles of  $\text{NH}_3$  that remain and the number of moles of  $\text{NH}_4^+$  that were produced. Accounting for the volume of the solution, you calculate the following concentrations:

$$[\text{NH}_3] = 3.5 \times 10^{-2} \text{ M}$$

$$[\text{NH}_4^+] = 3.2 \times 10^{-2} \text{ M}$$

Recognizing that this is a buffer solution, you can use the Henderson–Hasselbalch equation ( $K_a$  for  $\text{NH}_4^+ = 5.6 \times 10^{-10}$ ) to solve for the pH, which is **9.29**. If you don't recognize that this is a buffer solution, you can solve this as an equilibrium problem based on the hydrolysis reaction of  $\text{NH}_3$ .

c. This part is solved in nearly the same manner as part b, only now the number of moles of  $\text{H}_3\text{O}^+$  is equal to the number of moles of  $\text{NH}_3$ . Using the reaction stoichiometry and keeping track of the total solution volume (50 mL), you determine

$$[\text{NH}_4^+] = 5.0 \times 10^{-2} \text{ M}$$

$$[\text{NH}_3] = 0 \text{ M}$$

This is ~~not a buffer solution because the~~  $[\text{NH}_3] = 0 \text{ M}$ ; therefore, we need to solve an equilibrium problem of the hydrolysis of  $\text{NH}_4^+$ , which indicates  $\text{pH} = 5.28$ . Note how this agrees with Figure 16.14.

d. Finally, you need to calculate the concentration of  $\text{H}_3\text{O}^+$  that is due to the excess HCl added beyond the equivalence point. Remembering the titration reaction

You perform the stoichiometry calculation by first determining the moles of  $\text{H}_3\text{O}^+$  that reacted with the  $\text{NH}_3$ . Then you use this quantity to determine the amount of unreacted  $\text{H}_3\text{O}^+$  that remains in solution.

$$\text{Mol H}_3\text{O}^+ \text{ reacted} = 2.5 \times 10^{-3} \text{ mol}$$

$$\text{Mol H}_3\text{O}^+ \text{ remaining} = (3.1 \times 10^{-3} \text{ mol} - 2.5 \times 10^{-3} \text{ mol}) = 6.0 \times 10^{-4} \text{ mol}$$

(continued)

**Example 16.15** (continued)

In order to calculate the pH, you first need to know the concentration of the  $\text{H}_3\text{O}^+$ . Taking into account the total volume of solution (56 mL), you determine the concentration of  $\text{H}_3\text{O}^+$ .

$$[\text{H}_3\text{O}^+] = \frac{6.0 \times 10^{-4} \text{ mol}}{0.056 \text{ L}} = 1.1 \times 10^{-2} \text{ M}$$

Therefore, the pH = **1.96**.

**Answer Check** If you know the general attributes of the different titration curves, you can make sure that your numerical answers fall on the curve. Compare the answers in this problem with the curve in Figure 16.14.

**Exercise 16.16** An 80.0-mL sample of 0.200 M ammonia is titrated with 0.100 M hydrochloric acid.  $K_b$  for ammonia is  $1.8 \times 10^{-5}$ . Calculate the pH of the solution at each of the following points of the titration: a. before the addition of any HCl; b. halfway to the equivalence point; c. at the equivalence point; d. after the addition of 175 mL of 0.100 M HCl.

See Problems 16.91 and 16.92.

## A Checklist for Review

### Summary of Facts and Concepts

When a weak acid dissolves in water, it ionizes to give hydronium ions and the conjugate base ions. The equilibrium constant for this *acid ionization* is

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]}$$

where HA is the general formula for the acid. The constant  $K_a$  can be determined from the pH of an acid solution of known concentration. Once obtained, the acid-ionization constant can be used to find the concentrations of species in any solution of the acid. In the case of a *diprotic* acid,  $\text{H}_2\text{A}$ , the concentration of  $\text{H}_3\text{O}^+$  and  $\text{HA}^-$  are calculated from  $K_{a1}$ , and the concentration of  $\text{A}^{2-}$  equals  $K_{a2}$ . Similar considerations apply to *base ionizations*.

Solutions of salts may be acidic or basic because of *hydrolysis* of the ions. The equilibrium constant for hydrolysis equals  $K_a$  for a cation or  $K_b$  for an anion. Calculation of the pH of a solution of a salt in which one ion hydrolyzes is fundamentally the same as calculation of the pH of a solution of an acid or base. However,  $K_a$  or  $K_b$  for an ion is usually obtained from the conjugate base or acid by applying the equation  $K_a K_b = K_w$ .

A *buffer* is a solution that can resist changes in pH when small amounts of acid or base are added to it. A buffer contains either a weak acid and its conjugate base or a weak base and its conjugate acid. The concentrations of acid and base conjugates are approximately equal. Different pH ranges are possible for acid–base conjugates, depending on their ionization constants.

An *acid–base titration curve* is a plot of the pH of the solution against the volume of reactant added. During the titration of a strong acid by a strong base, the pH changes slowly at first. Then, as the amount of base nears the stoichiometric value—that is, nears the *equivalence point*—the pH rises abruptly, changing by several units. The pH at the equivalence point is 7.0. A similar curve is obtained when a weak acid is titrated by a strong base. However, the pH changes less at the equivalence point. Moreover, the pH at the equivalence point is greater than 7.0 because of hydrolysis of the salt produced. An indicator must be chosen that changes color within a pH range near the equivalence point, where the pH changes rapidly.

### Learning Objectives

#### 16.1 Acid-Ionization Equilibria

- Write the chemical equation for a weak acid undergoing *acid ionization* in aqueous solution.
- Define *acid-ionization constant* and *degree of ionization*.
- Determine  $K_a$  from the solution pH. **Example 16.1**
- Calculate concentrations of species in a weak acid solution using  $K_a$  (approximation method). **Example 16.2**

### Important Terms

**acid-ionization constant**  
**degree of ionization**

- State the assumption that allows for using approximations when solving problems.
- Calculate concentrations of species in a weak acid solution using  $K_a$  (quadratic formula). **Example 16.3**

### 16.2 Polyprotic Acids

- State the general trend in the ionization constants of a polyprotic acid.
- Calculate concentrations of species in a solution of a diprotic acid. **Example 16.4**

### 16.3 Base-Ionization Equilibria

- Write the chemical equation for a weak base undergoing ionization in aqueous solution.
- Define *base-ionization constant*.
- Calculate concentrations of species in a weak base solution using  $K_b$ . **Example 16.5**

**base-ionization constant**

### 16.4 Acid–Base Properties of Salt Solutions

- Write the *hydrolysis* reaction of an ion to form an acidic solution.
- Write the hydrolysis reaction of an ion to form a basic solution.
- Predict whether a salt solution is acidic, basic, or neutral. **Example 16.6**
- Obtain  $K_a$  from  $K_b$  or  $K_b$  from  $K_a$ . **Example 16.7**
- Calculating concentrations of species in a salt solution. **Example 16.8**

**hydrolysis**

### 16.5 Common-Ion Effect

- Explain the common-ion effect.
- Calculate the common-ion effect on acid ionization (effect of a strong acid). **Example 16.9**
- Calculate the common-ion effect on acid ionization (effect of a conjugate base). **Example 16.10**

**common-ion effect**

### 16.6 Buffers

- Define *buffer* and *buffer capacity*.
- Describe the pH change of a buffer solution with the addition of acid or base.
- Calculate the pH of a buffer from given volumes of solution. **Example 16.11**
- Calculate the pH of a buffer when a strong acid or a strong base is added. **Example 16.12**
- Learn the *Henderson–Hasselbalch* equation.
- State when the Henderson–Hasselbalch equation can be applied.

**buffer**  
**Henderson–Hasselbalch equation**

### 16.7 Acid–Base Titration Curves

- Define *equivalence point*.
- Describe the curve for the titration of a strong acid by a strong base.
- Calculate the pH of a solution of a strong acid and a strong base. **Example 16.13**
- Describe the curve for the titration of a weak acid by a strong base.
- Calculate the pH at the equivalence point in the titration of a weak acid by a strong base. **Example 16.14**

**acid–base titration curve**  
**equivalence point**

- Describe the curve for the titration of a weak base by a strong acid.
- Calculate the pH of a solution at several points of a titration of weak base by a strong acid. **Example 16.15**

### Key Equations

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]}$$

$$K_b = \frac{[\text{HB}^+][\text{OH}^-]}{[\text{B}]}$$

$$K_a K_b = K_w$$

$$\text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]}$$

## Questions and Problems

### Self-Assessment and Review Questions

**Key:** These questions test your understanding of the ideas you worked with in the chapter. These problems vary in difficulty and often can be used for the basis of discussion.

**16.1** Write an equation for the ionization of hydrogen cyanide, HCN, in aqueous solution. What is the equilibrium expression  $K_a$  for this acid ionization?

**16.2** Which of the following is the weakest acid:  $\text{HClO}_4$ , HCN, or  $\text{HC}_2\text{H}_3\text{O}_2$ ? See Table 15.1 and Table 16.1.

**16.3** Briefly describe two methods for determining  $K_a$  for a weak acid.

**16.4** Describe how the degree of ionization of a weak acid changes as the concentration increases.

**16.5** Consider a solution of 0.0010 M HF ( $K_a = 6.8 \times 10^{-4}$ ). In solving for the concentrations of species in this solution, could you use the simplifying assumption in which you neglect  $x$  in the denominator of the equilibrium equation? Explain.

**16.6** Phosphorous acid,  $\text{H}_2\text{PHO}_3$ , is a diprotic acid. Write equations for the acid ionizations. Write the expressions for  $K_{a1}$  and  $K_{a2}$ .

**16.7**  $\text{H}_2\text{A}$  is a weak diprotic acid having  $K_{a1} = 4.5 \times 10^{-4}$  and  $K_{a2} = 6.7 \times 10^{-8}$ . If the concentration of  $\text{H}_2\text{A}$  is 0.45 M, what is the concentration of  $\text{A}^{2-}$ ?

**16.8** Write the equation for the ionization of aniline,  $\text{C}_6\text{H}_5\text{NH}_2$ , in aqueous solution. Write the expression for  $K_b$ .

**16.9** Which of the following is the strongest base:  $\text{NH}_3$ ,  $\text{C}_6\text{H}_5\text{NH}_2$ , or  $\text{CH}_3\text{NH}_2$ ? See Table 16.2.

**16.10** Do you expect a solution of anilinium chloride (aniline hydrochloride),  $\text{C}_6\text{H}_5\text{NH}_3\text{Cl}$ , to be acidic or basic? (Anilinium chloride is the salt of aniline and hydrochloric acid.) Write the equation for the reaction involved. What is the equilibrium expression? How would you obtain the value for the equilibrium constant from Table 16.2?

**16.11** What is meant by the common-ion effect? Give an example.

**16.12** The pH of 0.10 M  $\text{CH}_3\text{NH}_2$  (methylamine) is 11.8. When the chloride salt of methylamine,  $\text{CH}_3\text{NH}_3\text{Cl}$ , is added to this solution, does the pH increase or decrease? Explain, using Le Châtelier's principle and the common-ion effect.

**16.13** Define the term *buffer*. Give an example.

**16.14** What is meant by the capacity of a buffer? Describe a buffer with low capacity and the same buffer with greater capacity.

**16.15** Describe the pH changes that occur during the titration of a weak base by a strong acid. What is meant by the term *equivalence point*?

**16.16** If the pH is 8.0 at the equivalence point for the titration of a certain weak acid with sodium hydroxide, what indicator might you use? (See Figure 15.10.) Explain your choice.

**16.17** Which of the following salts would produce the most basic aqueous solution?

- a**  $\text{Ca}(\text{NO}_3)_2$       **b** LiI      **c** KCl  
**d**  $(\text{NH}_4)_2\text{SO}_4$       **e** KClO

**16.18** If you mix 0.10 mol of  $\text{NH}_3$  and 0.10 mol of HCl in a bucket of water, you would expect the resulting solution to be

- a** very basic      **b** slightly basic      **c** neutral  
**d** slightly acidic      **e** very acidic

**16.19** Hydrogen sulfide,  $\text{H}_2\text{S}$ , is a very weak diprotic acid. In a 0.10 M solution of this acid, which of the following would you expect to find in the *highest* concentration?

- a**  $\text{H}_2\text{S}$       **b**  $\text{H}_3\text{O}^+$       **c**  $\text{HS}^-$   
**d**  $\text{S}^{2-}$       **e**  $\text{OH}^-$

**16.20** If 20.0 mL of a 0.10 M NaOH solution is added to a 30.0-mL sample of a 0.10 M weak acid, HA, what is the pH of the resulting solution? ( $K_a = 1.8 \times 10^{-5}$  for HA)

- a** 2.87      **b** 2.74      **c** 4.74  
**d** 5.05      **e** 8.73

### Concept Explorations

**Key:** Concept explorations are comprehensive problems that provide a framework that will enable you to explore and learn many of the critical concepts and ideas in each chapter. If you master the concepts associated with these

explorations, you will have a better understanding of many important chemistry ideas and will be more successful in solving all types of chemistry problems. These problems are well suited for group work and for use as in-class activities.

what volume and concentration of NaA solution could you use in order to prepare the buffer?

**16.30** A friend of yours has performed three titrations: strong acid with a strong base, weak acid with a strong base, and weak base with a strong acid. He hands you the three titration curves, saying he has forgotten which is which. What attributes of the curves would you look at to identify each curve correctly?

**16.31** You are given the following acid–base titration data, where each point on the graph represents the pH after adding a given volume of titrant (the substance being added during the titration).

- What substance is being titrated, a strong acid, strong base, weak acid, or weak base?
- What is the pH at the equivalence point of the titration?
- What indicator might you use to perform this titration? Explain.

**16.32** The three flasks shown below depict the titration of an aqueous NaOH solution with HCl at different points. One represents the titration prior to the equivalence point, another represents the titration at the equivalence point, and the other represents the titration past the equivalence point. (Sodium ions and solvent water molecules have been omitted for clarity.)

- Write the balanced chemical equation for the titration.
- Label each of the beakers shown to indicate which point in the titration they represent.
- For each solution, indicate whether you expect it to be acidic, basic, or neutral.

## Practice Problems

**Key:** These problems are for practice in applying problem-solving skills. They are divided by topic, and some are keyed to exercises (see the ends of the exercises). The problems are arranged in matching pairs; the odd-numbered problem of each pair is listed first, and its answer is given in the back of the book.

**Note:** For values of  $K_a$  and  $K_b$  that are not given in the following problems, see Tables 16.1 and 16.2.

### Acid Ionization

**16.33** Write chemical equations for the acid ionizations of each of the following weak acids (express these in terms of  $\text{H}_3\text{O}^+$ ).

- HBrO (hypobromous acid)
- $\text{HClO}_2$  (chlorous acid)
- $\text{HNO}_2$  (nitrous acid)
- HCN (hydrocyanic acid)

**16.34** Write chemical equations for the acid ionizations of each of the following weak acids (express these in terms of  $\text{H}_3\text{O}^+$ ).

- $\text{HCO}_2\text{H}$  (formic acid)
- HF (hydrofluoric acid)
- $\text{HN}_3$  (hydrazoic acid)
- HOCN (cyanic acid)

**16.35** Acrylic acid, whose formula is  $\text{HC}_3\text{H}_3\text{O}_2$  or  $\text{HO}_2\text{CCH}=\text{CH}_2$ , is used in the manufacture of plastics. A 0.77 M aqueous solution of acrylic acid has a pH of 2.18. What is  $K_a$  for acrylic acid?

**16.36** Heavy metal azides, which are salts of hydrazoic acid,  $\text{HN}_3$ , are used as explosive detonators. A solution of

0.20 M hydrazoic acid has a pH of 3.21. What is the  $K_a$  for hydrazoic acid?

**16.37** Boric acid,  $\text{B}(\text{OH})_3$ , is used as a mild antiseptic. What is the pH of a 0.015 M aqueous solution of boric acid? What is the degree of ionization of boric acid in this solution? The hydronium ion arises principally from the reaction

The equilibrium constant for this reaction is  $5.9 \times 10^{-10}$ .

**16.38** Formic acid,  $\text{HCHO}_2$ , is used to make methyl formate (a fumigant for dried fruit) and ethyl formate (an artificial rum flavor). What is the pH of a 0.12 M solution of formic acid? What is the degree of ionization of  $\text{HCHO}_2$  in this solution? See Table 16.1 for  $K_a$ .

**16.39**  $\text{C}_6\text{H}_4\text{NH}_2\text{COOH}$ , *para*-aminobenzoic acid (PABA), is used in some sunscreen agents. Calculate the concentrations of hydronium ion and *para*-aminobenzoate ion,

$\text{C}_6\text{H}_4\text{NH}_2\text{COO}^-$ , in a  $0.080\text{ M}$  solution of the acid. The value of  $K_a$  is  $2.2 \times 10^{-5}$ .

**16.40** Barbituric acid,  $\text{HC}_4\text{H}_3\text{N}_2\text{O}_3$ , is used to prepare various barbiturate drugs (used as sedatives). Calculate the concentrations of hydronium ion and barbiturate ion in a  $0.10\text{ M}$  solution of the acid. The value of  $K_a$  is  $9.8 \times 10^{-5}$ .

**16.41** A solution of acetic acid,  $\text{HC}_2\text{H}_3\text{O}_2$ , on a laboratory shelf was of undetermined concentration. If the pH of the solution was found to be 2.57, what was the concentration of the acetic acid? The  $K_a$  of acetic acid is  $1.7 \times 10^{-5}$ .

**16.42** A chemist wanted to determine the concentration of a solution of lactic acid,  $\text{HC}_3\text{H}_5\text{O}_3$ . She found that the pH of the solution was 2.60. What was the concentration of the solution? The  $K_a$  of lactic acid is  $1.4 \times 10^{-4}$ .

**16.43** Hydrofluoric acid, HF, unlike hydrochloric acid, is a weak electrolyte. What is the hydronium-ion concentration and the pH of a  $0.040\text{ M}$  aqueous solution of HF?

**16.44** Chloroacetic acid,  $\text{HC}_2\text{H}_2\text{ClO}_2$ , has a greater acid strength than acetic acid, because the electronegative chlorine atom pulls electrons away from the O—H bond and thus weakens it. Calculate the hydronium-ion concentration and the pH of a  $0.0020\text{ M}$  solution of chloroacetic acid.  $K_a$  is  $1.3 \times 10^{-3}$ .

**16.45** What is the hydronium-ion concentration of a  $2.00\text{ M}$  solution of 2,6-dinitrobenzoic acid,  $(\text{NO}_2)_2\text{C}_6\text{H}_3\text{COOH}$ , for which  $K_a = 7.94 \times 10^{-2}$ ?

**16.46** What is the hydronium-ion concentration of a  $3.00 \times 10^{-4}\text{ M}$  solution of *p*-bromobenzoic acid,  $\text{BrC}_6\text{H}_4\text{COOH}$ , for which  $K_a = 1.00 \times 10^{-4}$ ?

**16.47** Phthalic acid,  $\text{H}_2\text{C}_8\text{H}_4\text{O}_4$ , is a diprotic acid used in the synthesis of phenolphthalein indicator.  $K_{a1} = 1.2 \times 10^{-3}$ , and  $K_{a2} = 3.9 \times 10^{-6}$ . **a** Calculate the hydronium-ion concentration of a  $0.015\text{ M}$  solution. **b** What is the concentration of the  $\text{C}_8\text{H}_4\text{O}_4^{2-}$  ion in the solution?

**16.48** Carbonic acid,  $\text{H}_2\text{CO}_3$ , can be found in a wide variety of body fluids (from dissolved  $\text{CO}_2$ ). **a** Calculate the

hydronium-ion concentration of a  $6.00 \times 10^{-4}\text{ M}$   $\text{H}_2\text{CO}_3$  solution. **b** What is the concentration of  $\text{CO}_3^{2-}$ ?

### Base Ionization

**16.49** Write the chemical equation for the base ionization of methylamine,  $\text{CH}_3\text{NH}_2$ . Write the  $K_b$  expression for methylamine.

**16.50** Write the chemical equation for the base ionization of aniline,  $\text{C}_6\text{H}_5\text{NH}_2$ . Write the  $K_b$  expression for aniline.

**16.51** Butylamine,  $\text{C}_4\text{H}_9\text{NH}_2$  is a weak base. A  $0.47\text{ M}$  aqueous solution of butylamine has a pH of 12.13. What is  $K_b$  for butylamine? Calculate the pH of a  $0.35\text{ M}$  aqueous solution of butylamine.

**16.52** Trimethylamine,  $(\text{CH}_3)_3\text{N}$ , is a gas with a fishy, ammonialike odor. An aqueous solution that is  $0.25\text{ M}$  trimethylamine has a pH of 11.63. What is  $K_b$  for trimethylamine? Calculate the pH of a  $0.35\text{ M}$  aqueous solution of trimethylamine.

**16.53** What is the concentration of hydroxide ion in a  $0.060\text{ M}$  aqueous solution of methylamine,  $\text{CH}_3\text{NH}_2$ ? What is the pH?

**16.54** What is the concentration of hydroxide ion in a  $0.21\text{ M}$  aqueous solution of hydroxylamine,  $\text{NH}_2\text{OH}$ ? What is the pH?

### Acid–Base Properties of Salt Solutions; Hydrolysis

**16.55** Note whether hydrolysis occurs for each of the following ions. If hydrolysis does occur, write the chemical equation for it. Then write the equilibrium expression for the acid or base ionization (whichever occurs).

- |                                     |                         |
|-------------------------------------|-------------------------|
| <b>a</b> $\text{NO}_3^-$            | <b>b</b> $\text{OCl}^-$ |
| <b>c</b> $\text{NH}_2\text{NH}_3^+$ | <b>d</b> $\text{Br}^-$  |

**16.56** Note whether hydrolysis occurs for each of the following ions. If hydrolysis does occur, write the chemical equation for it. Then write the equilibrium expression for the acid or base ionization (whichever occurs).

- |                                     |                             |
|-------------------------------------|-----------------------------|
| <b>a</b> $\text{CH}_3\text{NH}_3^+$ | <b>b</b> $\text{Cl}^-$      |
| <b>c</b> $\text{ClO}_2^-$           | <b>d</b> $\text{CO}_3^{2-}$ |

**16.57** Write the equation for the acid ionization of the  $\text{Zn}(\text{H}_2\text{O})_6^{2+}$  ion.

**16.58** Write the equation for the acid ionization of the  $\text{Cu}(\text{H}_2\text{O})_6^{2+}$  ion.

**16.59** For each of the following salts, indicate whether the aqueous solution will be acidic, basic, or neutral.

- |   |                                  |
|---|----------------------------------|
| <b>a</b> $\text{Zn}(\text{NO}_3)_2$           | <b>b</b> $\text{K}_2\text{SO}_4$ |
| <b>c</b> $\text{NH}_2\text{NH}_3\text{ClO}_4$ | <b>d</b> $\text{K}_2\text{SO}_3$ |

**16.60** Note whether the aqueous solution of each of the following salts will be acidic, basic, or neutral.

- |                                |  |
|--------------------------------|--|
| <b>a</b> $\text{Na}_2\text{S}$ | <b>b</b> $\text{Cu}(\text{NO}_2)_2$        |
| <b>c</b> $\text{KNO}_3$        | <b>d</b> $\text{CH}_3\text{NH}_3\text{Cl}$ |

**16.61** Decide whether solutions of the following salts are acidic, neutral, or basic.

- |                           |                            |
|---------------------------|----------------------------|
| <b>a</b> ammonium acetate | <b>b</b> anilinium acetate |
|---------------------------|----------------------------|

**16.62** Decide whether solutions of the following salts are acidic, neutral, or basic.

- |                           |                            |
|---------------------------|----------------------------|
| <b>a</b> ammonium cyanate | <b>b</b> anilinium cyanate |
|---------------------------|----------------------------|

**16.63** Obtain **a** the  $K_b$  value for  $\text{NO}_2^-$ ; **b** the  $K_a$  value for  $\text{C}_5\text{H}_5\text{NH}^+$  (pyridinium ion).

**16.64** Obtain **a** the  $K_b$  value for  $\text{C}_3\text{H}_3\text{O}_2^-$ ; **b** the  $K_a$  value for  $\text{NH}_3\text{OH}^+$  (hydroxylammonium ion).

**16.65** What is the pH of a 0.025 *M* aqueous solution of sodium propionate,  $\text{NaC}_3\text{H}_5\text{O}_2$ ? What is the concentration of propionic acid in the solution?

**16.66** Calculate the  $\text{OH}^-$  concentration and pH of a 0.0025 *M* aqueous solution of sodium cyanide,  $\text{NaCN}$ . Finally, obtain the hydronium-ion,  $\text{CN}^-$ , and  $\text{HCN}$  concentrations.

**16.67** Calculate the concentration of pyridine,  $\text{C}_5\text{H}_5\text{N}$ , in a solution that is 0.15 *M* pyridinium bromide,  $\text{C}_5\text{H}_5\text{NHBr}$ . What is the pH of the solution?

**16.68** What is the pH of a 0.30 *M* solution of methylammonium chloride,  $\text{CH}_3\text{NH}_3\text{Cl}$ ? What is the concentration of methylamine in the solution?

### Common-Ion Effect

**16.69** Calculate the degree of ionization of **a** 0.75 *M* HF (hydrofluoric acid); **b** the same solution that is also 0.12 *M* HCl.

**16.70** Calculate the degree of ionization of **a** 0.22 *M*  $\text{HCHO}_2$  (formic acid); **b** the same solution that is also 0.15 *M* HCl.

**16.71** What is the pH of a solution that is 0.600 *M*  $\text{HCHO}_2$  (formic acid) and 0.400 *M*  $\text{NaCHO}_2$ ?

**16.72** What is the pH of a solution that is 0.20 *M*  $\text{KOCN}$  and 0.10 *M*  $\text{HOCN}$  (cyanic acid)?

**16.73** What is the pH of a solution that is 0.10 *M*  $\text{CH}_3\text{NH}_2$  (methylamine) and 0.15 *M*  $\text{CH}_3\text{NH}_3\text{Cl}$  (methylammonium chloride)?

**16.74** What is the pH of a solution that is 0.15 *M*  $\text{C}_2\text{H}_5\text{NH}_2$  (ethylamine) and 0.10 *M*  $\text{C}_2\text{H}_5\text{NH}_3\text{Br}$  (ethylammonium bromide)?

### Buffers

**16.75** A buffer is prepared by adding 39.8 mL of 0.75 *M* NaF to 38.9 mL of 0.28 *M* HF. What is the pH of the final solution?

**16.76** A buffer is prepared by adding 115 mL of 0.30 *M*  $\text{NH}_3$  to 135 mL of 0.15 *M*  $\text{NH}_4\text{NO}_3$ . What is the pH of the final solution?

**16.77** What is the pH of a buffer solution that is 0.10 *M*  $\text{NH}_3$  and 0.10 *M*  $\text{NH}_4^+$ ? What is the pH if 12 mL of 0.20 *M* hydrochloric acid is added to 125 mL of buffer?

**16.78** A buffer is prepared by mixing 525 mL of 0.50 *M* formic acid,  $\text{HCHO}_2$ , and 475 mL of 0.50 *M* sodium formate,  $\text{NaCHO}_2$ . Calculate the pH. What would be the pH of 85 mL of the buffer to which 8.6 mL of 0.15 *M* hydrochloric acid had been added?

**16.79** What is the pH of a buffer solution that is 0.15 *M* chloroacetic acid and 0.10 *M* sodium chloroacetate?  $K_a = 1.3 \times 10^{-3}$ .

**16.80** What is the pH of a buffer solution that is 0.10 *M* propionic acid and 0.20 *M* sodium propionate?

**16.81** What is the pH of a buffer solution that is 0.15 *M* pyridine and 0.10 *M* pyridinium bromide?

**16.82** What is the pH of a buffer solution that is 0.15 *M* methylamine and 0.20 *M* methylammonium chloride?

**16.83** How many moles of sodium acetate must be added to 2.0 L of 0.10 *M* acetic acid to give a solution that has a pH equal to 4.90? Ignore the volume change due to the addition of sodium acetate.

**16.84** How many moles of hydrofluoric acid, HF, must be added to 250 mL of 0.25 *M* sodium fluoride to give a buffer of pH 3.50? Ignore the volume change due to the addition of hydrofluoric acid.

### Titration Curves

**16.85** What is the pH of a solution in which 15 mL of 0.10 *M* NaOH is added to 25 mL of 0.10 *M* HCl?

**16.86** What is the pH of a solution in which 35 mL of 0.10 *M* NaOH is added to 25 mL of 0.10 *M* HCl?

**16.87** A 1.24-g sample of benzoic acid was dissolved in water to give 50.0 mL of solution. This solution was titrated with 0.180 *M* NaOH. What was the pH of the solution when the equivalence point was reached?

**16.88** A 0.400-g sample of propionic acid was dissolved in water to give 50.0 mL of solution. This solution was titrated with 0.150 *M* NaOH. What was the pH of the solution when the equivalence point was reached?

**16.89** Find the pH of the solution obtained when 32 mL of 0.087 *M* ethylamine is titrated to the equivalence point with 0.15 *M* HCl.

**16.90** What is the pH at the equivalence point when 22 mL of 0.20 *M* hydroxylamine is titrated with 0.10 *M* HCl?

**16.91** A 50.0-mL sample of a 0.100 *M* solution of NaCN is titrated by 0.200 *M* HCl.  $K_b$  for  $\text{CN}^-$  is  $2.0 \times 10^{-5}$ . Calculate the pH of the solution: **a** prior to the start of the titration; **b** after the addition of 15.0 mL of 0.200 *M* HCl; **c** at the equivalence point; **d** after the addition of 30.0 mL of 0.200 *M* HCl.

**16.92** Sodium benzoate,  $\text{NaC}_7\text{H}_5\text{O}_2$ , is used as a preservative in foods. Consider a 50.0-mL sample of 0.250 *M*  $\text{NaC}_7\text{H}_5\text{O}_2$  being titrated by 0.200 *M* HBr. Calculate the pH of the solution: **a** when no HBr has been added; **b** after the addition of 50.0 mL of the HBr solution; **c** at the equivalence point; **d** after the addition of 75.00 mL of the HBr solution. The  $K_b$  value for the benzoate ion is  $1.6 \times 10^{-10}$ .

**16.93** Calculate the pH of a solution obtained by mixing 25.00 mL of 0.19 *M*  $\text{NH}_3$  with 25.00 mL of 0.060 *M* HCl.

**16.94** Calculate the pH of a solution obtained by mixing 35.0 mL of 0.15 *M* acetic acid with 27.0 mL of 0.10 *M* sodium acetate.

## General Problems

**Key:** These problems provide more practice but are not divided by topic or keyed to exercises. Each section ends with essay questions, each of which is color coded to refer to the *A Chemist Looks at Environment* (green) chapter essay on which it is based. Odd-numbered problems and the even-numbered problems that follow are similar; answers to all odd-numbered problems except the essay questions are given in the back of the book.

**16.95** Salicylic acid,  $C_6H_4OHCOOH$ , is used in the manufacture of acetylsalicylic acid (aspirin) and methyl salicylate (wintergreen flavor). A saturated solution of salicylic acid contains 2.2 g of the acid per liter of solution and has a pH of 2.43. What is the value of  $K_a$ ?

**16.96** Cyanoacetic acid,  $CH_2CNCOOH$ , is used in the manufacture of barbiturate drugs. An aqueous solution containing 5.0 g in a liter of solution has a pH of 1.89. What is the value of  $K_a$ ?

**16.97** A 0.050 *M* aqueous solution of sodium hydrogen sulfate,  $NaHSO_4$ , has a pH of 1.73. Calculate  $K_{a2}$  for sulfuric acid. Sulfuric acid is a strong acid, so you can ignore hydrolysis of the  $HSO_4^-$  ion.

**16.98** A 0.10 *M* aqueous solution of sodium dihydrogen phosphate,  $NaH_2PO_4$ , has a pH of 4.10. Calculate  $K_{a2}$  for phosphoric acid. You can ignore hydrolysis of the  $H_2PO_4^-$  ion.

**16.99** Calculate the base-ionization constants for  $CN^-$  and  $CO_3^{2-}$ . Which ion is the stronger base?

**16.100** Calculate the base-ionization constants for  $PO_4^{3-}$  and  $SO_4^{2-}$ . Which ion is the stronger base?

**16.101** Calculate the pH of a 0.072 *M* aqueous solution of aluminum chloride,  $AlCl_3$ . The acid ionization of hydrated aluminum ion is

and  $K_a$  is  $1.4 \times 10^{-5}$ .

**16.102** Calculate the pH of a 0.10 *M* aqueous solution of zinc chloride,  $ZnCl_2$ . The acid ionization of hydrated zinc ion is

and  $K_a$  is  $2.5 \times 10^{-10}$ .

**16.103** An artificial fruit beverage contains 11.0 g of tartaric acid,  $H_2C_4H_4O_6$ , and 20.0 g of its salt, potassium hydrogen tartrate, per liter. What is the pH of the beverage?  $K_{a1} = 1.0 \times 10^{-3}$ .

**16.104** A buffer is made by dissolving 12.5 g of sodium dihydrogen phosphate,  $NaH_2PO_4$ , and 15.0 g of disodium hydrogen phosphate,  $Na_2HPO_4$ , in a liter of solution. What is the pH of the buffer?

**16.105** Blood contains several acid–base systems that tend to keep its pH constant at about 7.4. One of the most important buffer systems involves carbonic acid and hydrogen

carbonate ion. What must be the ratio of  $[HCO_3^-]$  to  $[H_2CO_3]$  in the blood if the pH is 7.40?

**16.106** Codeine,  $C_{18}H_{21}NO_3$ , is an alkaloid ( $K_b = 6.2 \times 10^{-9}$ ) used as a painkiller and cough suppressant. A solution of codeine is acidified with hydrochloric acid to pH 4.50. What is the ratio of the concentration of the conjugate acid of codeine to that of the base codeine?

**16.107** Calculate the pH of a solution obtained by mixing 456 mL of 0.10 *M* hydrochloric acid with 285 mL of 0.15 *M* sodium hydroxide. Assume the combined volume is the sum of the two original volumes.

**16.108** Calculate the pH of a solution made up from 2.0 g of potassium hydroxide dissolved in 115 mL of 0.19 *M* perchloric acid. Assume the change in volume due to adding potassium hydroxide is negligible.

**16.109** Find the pH of the solution obtained when 25 mL of 0.065 *M* benzylamine,  $C_7H_7NH_2$ , is titrated to the equivalence point with 0.050 *M* hydrochloric acid.  $K_b$  for benzylamine is  $4.7 \times 10^{-10}$ .

**16.110** What is the pH of the solution obtained by titrating 1.30 g of sodium hydrogen sulfate,  $NaHSO_4$ , dissolved in 50.0 mL of water with 0.175 *M* sodium hydroxide until the equivalence point is reached? Assume that any volume change due to adding the sodium hydrogen sulfate or to mixing the solutions is negligible.

**16.111** Ionization of the first proton from  $H_2SO_4$  is complete ( $H_2SO_4$  is a strong acid); the acid-ionization constant for the second proton is  $1.1 \times 10^{-2}$ . **a** What would be the approximate hydronium-ion concentration in 0.100 *M*  $H_2SO_4$  if ionization of the second proton were ignored? **b** The ionization of the second proton must be considered for a more exact answer, however. Calculate the hydronium-ion concentration in 0.100 *M*  $H_2SO_4$ , accounting for the ionization of both protons.

**16.112** Ionization of the first proton from  $H_2SeO_4$  is complete ( $H_2SeO_4$  is a strong acid); the acid-ionization constant for the second proton is  $1.2 \times 10^{-2}$ . **a** What would be the approximate hydronium-ion concentration in 0.150 *M*  $H_2SeO_4$  if ionization of the second proton were ignored? **b** The ionization of the second proton must be considered for a more exact answer, however. Calculate the hydronium-ion concentration in 0.150 *M*  $H_2SeO_4$ , accounting for the ionization of both protons.

**16.113** Methylammonium chloride is a salt of methylamine,  $CH_3NH_2$ . A 0.10 *M* solution of this salt has a pH of 5.82.

**a** Calculate the value for the equilibrium constant for the reaction

**b** What is the  $K_b$  value for methylamine?

**c** What is the pH of a solution in which 0.450 mol of solid methylammonium chloride is added to 1.00 L of a 0.250 *M* solution of methylamine? Assume no volume change.

**16.114** Sodium benzoate is a salt of benzoic acid,  $C_6H_5COOH$ . A 0.15 *M* solution of this salt has a pOH of 5.31 at room temperature.

- a** Calculate the value for the equilibrium constant for the reaction

- b** What is the  $K_a$  value for benzoic acid?  
**c** Benzoic acid has a low solubility in water. What is its molar solubility if a saturated solution has a pH of 2.83 at room temperature?

**16.115** Each of the following statements concerns a 0.010 *M* solution of a weak acid, HA. Briefly describe why each statement is either true or false.

- a** [HA] is approximately equal to 0.010 *M*.  
**b** [HA] is much greater than  $[\text{A}^-]$ .  
**c**  $[\text{OH}^-]$  is approximately equal to  $[\text{H}_3\text{O}^+]$ .  
**d** The pH is 2.  
**e** The  $\text{H}_3\text{O}^+$  concentration is 0.010 *M*.  
**f**  $[\text{H}_3\text{O}^+]$  is approximately equal to  $[\text{A}^-]$ .

**16.116** Each of the following statements concerns a 0.10 *M* solution of a weak organic base, B. Briefly describe why each statement is either true or false.

- a** [B] is approximately equal to 0.10 *M*.  
**b** [B] is much greater than  $[\text{HB}^+]$ .  
**c**  $[\text{H}_3\text{O}^+]$  is greater than  $[\text{HB}^+]$ .  
**d** The pH is 13.  
**e**  $[\text{HB}^+]$  is approximately equal to  $[\text{OH}^-]$ .  
**f**  $[\text{OH}^-]$  equals 0.10 *M*.

**16.117** A 0.288-g sample of an unknown monoprotic organic acid is dissolved in water and titrated with a 0.115 *M* sodium hydroxide solution. After the addition of 17.54 mL of base, a pH of 4.92 is recorded. The equivalence point is reached when a total of 33.83 mL of NaOH is added.

- a** What is the molar mass of the organic acid?  
**b** What is the  $K_a$  value for the acid? The  $K_a$  value could have been determined very easily if a pH measurement had been made after the addition of 16.92 mL of NaOH. Why?

**16.118** A 0.239-g sample of unknown organic base is dissolved in water and titrated with a 0.135 *M* hydrochloric acid solution. After the addition of 18.35 mL of acid, a pH of 10.73 is recorded. The equivalence point is reached when a total of 39.24 mL of HCl is added. The base and acid combine in a 1:1 ratio.

- a** What is the molar mass of the organic base?  
**b** What is the  $K_b$  value for the base? The  $K_b$  value could have been determined very easily if a pH measurement had been made after the addition of 19.62 mL of HCl. Why?

**16.119** **a** Draw a pH titration curve that represents the titration of 50.0 mL of 0.10 *M*  $\text{NH}_3$  by the addition of 0.10 *M* HCl from a buret. Label the axes and put a scale on each axis. Show where the equivalence point and the buffer region are on the titration curve. You should do calculations for the 0%, 30%, 50%, and 100% titration points.

**b** Is the solution neutral, acidic, or basic at the equivalence point? Why?

**16.120** **a** Draw a pH titration curve that represents the titration of 25.0 mL of 0.15 *M* propionic acid,  $\text{CH}_3\text{CH}_2\text{COOH}$ , by the addition of 0.15 *M* KOH from a buret. Label the axes and put a scale on each axis. Show where the equivalence

point and the buffer region are on the titration curve. You should do calculations for the 0%, 50%, 60%, and 100% titration points. **b** Is the solution neutral, acidic, or basic at the equivalence point? Why?

**16.121** The equilibrium equations and  $K_a$  values for three reaction systems are given below.

- a** Which conjugate pair would be best for preparing a buffer with a pH of 2.88?  
**b** How would you prepare 50 mL of a buffer with a pH of 2.88 assuming that you had available 0.10 *M* solutions of each pair?

**16.122** The equilibrium equations and  $K_a$  values for three reaction systems are given below.

- a** Which conjugate pair would be best for preparing a buffer with a pH of 6.96? Why?  
**b** How would you prepare 100 mL of a buffer with a pH of 6.96 assuming that you had available 0.10 *M* solutions of each pair?

**16.123** A 25.0-mL sample of hydroxylamine is titrated to the equivalence point with 35.8 mL of 0.150 *M* HCl.

- a** What was the concentration of the original hydroxylamine solution?  
**b** What is the pH at the equivalence point?  
**c** Which indicators, bromphenol blue, methyl red, or phenolphthalein, should be used to detect the end point of the titration? Why?

**16.124** A 25.00-mL sample contains 0.562 g of  $\text{NaHCO}_3$ . This sample is used to standardize a NaOH solution. At the equivalence point, 40.95 mL of NaOH has been added.

- a** What was the concentration of the NaOH?  
**b** What is the pH at the equivalence point?  
**c** Which indicator, bromthymol blue, methyl violet, or alizarin yellow R, should be used in the titration? Why?

**16.125** A solution made up of 1.0 *M*  $\text{NH}_3$  and 0.50 *M*  $(\text{NH}_4)_2\text{SO}_4$  has a pH of 9.26.

- a** Write the net ionic equation that represents the reaction of this solution with a strong acid.  
**b** Write the net ionic equation that represents the reaction of this solution with a strong base.  
**c** To 100. mL of this solution, 10.0 mL of 1.00 *M* HCl is added. How many moles of  $\text{NH}_3$  and  $\text{NH}_4^+$  are present in the reaction system before and after the addition of the HCl? What is the pH of the resulting solution?

**d** Why did the pH change only slightly upon the addition of HCl?

**16.126** A solution is prepared from 0.150 mol of formic acid and enough water to make 0.425 L of solution.

**a** Determine the concentrations of  $\text{H}_3\text{O}^+$  and  $\text{HCOO}^-$  in this solution.

**b** Determine the  $\text{H}_3\text{O}^+$  concentration that would be necessary to decrease the  $\text{HCOO}^-$  concentration above by a factor of 10. How many milliliters of 2.00 M HCl would be required to produce this solution? Consider that the solution was made by combining the HCl, the  $\text{HCOOH}$ , and enough water to make 0.425 L of solution.

**c** Qualitatively, how can you account for the differences in the percentage dissociation of formic acid in parts a and b of this problem?

**16.127** An important component of blood is the buffer combination of dihydrogen phosphate ion and the hydrogen phosphate ion. Consider blood with a pH of 7.44.

**a** What is the ratio of  $[\text{H}_2\text{PO}_4^-]$  to  $[\text{HPO}_4^{2-}]$ ?

**b** What does the pH become if 25% of the hydrogen phosphate ions are converted to dihydrogen phosphate ion?

**c** What does the pH become if 15% of the dihydrogen phosphate ions are converted to hydrogen phosphate ions?

**16.128** An important component of blood is the buffer combination of bicarbonate ion and carbonic acid. Consider blood with a pH of 7.42.

**a** What is the ratio of  $[\text{H}_2\text{CO}_3]$  to  $[\text{HCO}_3^-]$ ?

**b** What does the pH become if 15% of the bicarbonate ions are converted to carbonic acid?

**c** What does the pH become if 25% of the carbonic acid molecules are converted to bicarbonate ions?

**16.129** Tartaric acid is a weak diprotic fruit acid with  $K_{a1} = 1.0 \times 10^{-3}$  and  $K_{a2} = 4.6 \times 10^{-5}$ .

**a** Letting the symbol  $\text{H}_2\text{A}$  represent tartaric acid, write the chemical equations that represent  $K_{a1}$  and  $K_{a2}$ . Write the chemical equation that represents  $K_{a1} \times K_{a2}$ .

**b** Qualitatively describe the relative concentrations of

$\text{H}_2\text{A}$ ,  $\text{HA}^-$ ,  $\text{A}^{2-}$ , and  $\text{H}_3\text{O}^+$  in a solution that is about 0.5 M in tartaric acid.

**c** Calculate the pH of a 0.0250 M tartaric acid solution and the equilibrium concentration of  $[\text{H}_2\text{A}]$ .

**d** What is the  $\text{A}^{2-}$  concentration in solutions **b** and **c**?

**16.130** Malic acid is a weak diprotic organic acid with  $K_{a1} = 4.0 \times 10^{-4}$  and  $K_{a2} = 9.0 \times 10^{-6}$ .

**a** Letting the symbol  $\text{H}_2\text{A}$  represent malic acid, write the chemical equations that represent  $K_{a1}$  and  $K_{a2}$ . Write the chemical equation that represents  $K_{a1} \times K_{a2}$ .

**b** Qualitatively describe the relative concentrations of  $\text{H}_2\text{A}$ ,  $\text{HA}^-$ ,  $\text{A}^{2-}$ , and  $\text{H}_3\text{O}^+$  in a solution that is about one molar in malic acid.

**c** Calculate the pH of a 0.0175 M malic acid solution and the equilibrium concentration of  $[\text{H}_2\text{A}]$ .

**d** What is the  $\text{A}^{2-}$  concentration in solutions **b** and **c**?

**16.131** A quantity of 0.25 M sodium hydroxide is added to a solution containing 0.15 mol of acetic acid. The final volume of the solution is 375 mL and the pH of this solution is 4.45.

**a** What is the molar concentration of the sodium acetate?

**b** How many milliliters of sodium hydroxide were added to the original solution?

**c** What was the original concentration of the acetic acid?

**16.132** A quantity of 0.15 M hydrochloric acid is added to a solution containing 0.10 mol of sodium acetate. Some of the sodium acetate is converted to acetic acid, resulting in a final volume of 650 mL of solution. The pH of the final solution is 4.56.

**a** What is the molar concentration of the acetic acid?

**b** How many milliliters of hydrochloric acid were added to the original solution?

**c** What was the original concentration of the sodium acetate?

**16.133** How can you account for the fact that normal rain is slightly acidic?

**16.134** How is acid rain defined? What is the source of the low pH of acid rain?

## Strategy Problems

**Key:** As noted earlier, all of the practice and general problems are matched pairs. This section is a selection of problems that are not in matched-pair format. These challenging problems require that you employ many of the concepts and strategies that were developed in the chapter. In some cases, you will have to integrate several concepts and operational skills in order to solve the problem successfully.

**16.135** A 30.0-mL sample of 0.05 M  $\text{HClO}$  is titrated by a 0.0250 M KOH solution.  $K_a$  for  $\text{HClO}$  is  $3.5 \times 10^{-8}$ . Calculate **a** the pH when no base has been added; **b** the pH when 30.00 mL of the base has been added; **c** the pH at the equivalence point; **d** the pH when an additional 4.00 mL of the KOH solution has been added beyond the equivalence point.

**16.136** A 0.108 M sample of a weak acid is 3.95% ionized in solution. What is the hydroxide concentration of this solution?

**16.137** A generic base,  $\text{B}^-$ , is added to 2.25 L of water. The pH of the solution is found to be 10.10. What is the

concentration of the base  $\text{B}^-$  in this solution?  $K_a$  for the acid  $\text{HB}$  at 25°C is  $1.99 \times 10^{-9}$ .

**16.138** Calculate the pH of a solution made by mixing 0.62 L of 0.10 M  $\text{NH}_4\text{Cl}$  with 0.50 L of 0.10 M NaOH.  $K_b$  for  $\text{NH}_3$  is  $1.8 \times 10^{-5}$ .

**16.139** Cyanic acid,  $\text{HOCN}$ , is a weak acid with a  $K_a$  value of  $3.5 \times 10^{-4}$  at 25°C. In a 0.293 M solution of the acid, the degree of ionization is  $3.5 \times 10^{-2}$ . Calculate the degree of ionization in a 0.293 M solution to which sufficient HCl is added to make it  $4.19 \times 10^{-2}$  M HCl in the given volume.

**16.140** The  $K_b$  for  $\text{NH}_3$  is  $1.8 \times 10^{-5}$  at 25°C. Calculate the pH of a buffer solution made by mixing 65.1 mL of 0.142 M  $\text{NH}_3$  with 38.0 mL of 0.172 M  $\text{NH}_4\text{Cl}$  at 25°C. Assume that the volumes of the solutions are additive.

**16.141**  $K_a$  for formic acid is  $1.7 \times 10^{-4}$  at 25°C. A buffer is made by mixing 529 mL of 0.465 M formic acid,  $\text{HCHO}_2$ , and 494 mL of 0.524 M sodium formate,  $\text{NaCHO}_2$ . Calculate the pH of this solution at 25°C after 110. mL of 0.152 M HCl has been added to this buffer.

**16.142**  $K_a$  for acetic acid is  $1.7 \times 10^{-5}$  at  $25^\circ\text{C}$ . A buffer solution is made by mixing 52.1 mL of 0.122  $M$  acetic acid with 46.1 mL of 0.182  $M$  sodium acetate. Calculate the pH of this solution at  $25^\circ\text{C}$  after the addition of 5.82 mL of 0.125  $M$  NaOH.

**16.143** Calculate the pH of a solution made by mixing 7.52 mL of  $4.9 \times 10^{-2} M$   $\text{Ca}(\text{OH})_2$  with 22.5 mL of 0.11  $M$  HCl.

**16.144** A 0.150  $M$  solution of NaClO is prepared by dissolving NaClO in water. A 50.0-mL sample of this solution is titrated with 0.100  $M$  HCl. Calculate the pH of the solution at each of the following points of the titration: **a** prior to the addition of any HCl; **b** halfway to the equivalence point; **c** at the equivalence point; **d** after 5.00 mL of HCl has been added beyond the equivalence point.  $K_a$  for HClO is  $3.5 \times 10^{-8}$ .

**16.145** A solution is prepared by dissolving ammonium nitrite in water. Predict whether the solution would be acidic or basic. If you want to make the solution have a neutral pH, which of the following could be added to achieve this result: HCl, NaCl, or KOH? Justify your answer.

**16.146** Two samples of 1.00  $M$  HCl of equivalent volumes are prepared. One sample is titrated to the equivalence point with a 1.00  $M$  solution of sodium hydroxide, while the other sample is titrated to the equivalence point with a 1.00  $M$  solution of calcium hydroxide.

- Compare the volumes of sodium hydroxide and calcium hydroxide required to reach the equivalence point for each titration.
- Determine the pH of each solution halfway to the equivalence point.
- Determine the pH of each solution at the equivalence point.

**16.147** You have the following solutions at your disposal to prepare a buffer solution with a pH greater than 7.0:

50.0 mL of 0.10 $M$ $\text{NH}_3$	20.0 mL of 0.10 $M$ NaCl
55.0 mL of 0.10 $M$ NaOH	20.0 mL of 0.10 $M$ $\text{HNO}_3$
50.0 mL of 0.10 $M$ HCl	20.0 mL of 0.10 $M$ KOH

- Assuming that you are going to mix the entire quantity of the listed solutions to prepare the buffer, which two solutions would you use?
- Calculate the pH of the buffer solution that you prepared in part a.

**16.148** A sample of  $\text{NH}_4\text{Cl}$  is prepared for titration by dissolving the salt in water, making 100.0 mL of solution. A second sample of  $\text{NH}_4\text{Cl}$  of identical mass is used to prepare 200.0 mL of solution. A solution of 0.10  $M$  NaOH or 0.10  $M$  HCl may be used to perform the titration.

- Which solution, the 0.10  $M$  NaOH or 0.10  $M$  HCl, should be used to perform the titration? Justify your answer?
- Compare the volume of titrant selected in part a that you would need to reach the equivalence point of the titrations for each of the samples.
- Compare the pH of the two solutions at the equivalence point of the titrations (assume additive volumes).

**16.149** A solution of weak base is titrated to the equivalence point with a strong acid. Which one of the following statements is most likely to be correct?

- The pH of the solution at the equivalence point is 7.0.
- The pH of the solution is greater than 13.0.
- The pH of the solution is less than 2.0.
- The pH of the solution is between 2.0 and 7.0.
- The pH of the solution is between 7.0 and 13.0.

The reason that best supports my choosing the answer above is

- Whenever a solution is titrated with a strong acid, the solution will be very acidic.
- Because the solution contains a weak base and the acid (titrant) is used up at the equivalence point, the solution will be basic.
- Because the solution contains the conjugate acid of the weak base at the equivalence point, the solution will be acidic.

**16.150** A buffer solution is prepared by mixing equal volumes of 0.10  $M$   $\text{NaNO}_2$  and 0.10  $M$   $\text{HNO}_2$  solutions.

- Calculate the pH of this solution.
- How would the buffer capacity of 500 mL of this buffer solution compare to the buffer capacity of 1000 mL of the solution? Explain your reasoning.
- If you had 2.0 L of this buffer solution, what is the minimum volume of 0.10  $M$   $\text{Ca}(\text{OH})_2$  required to exceed the buffer capacity?

## Capstone Problems

**Key:** The problems under this heading combine skills, strategies, and concepts learned in previous chapters with those introduced in the current one.

**16.151** The pH of a white vinegar solution is 2.45. This vinegar is an aqueous solution of acetic acid with a density of 1.09 g/mL. What is the mass percentage of acetic acid in the solution?

**16.152** The pH of a household cleaning solution is 11.50. This cleanser is an aqueous solution of ammonia with a density of 1.00 g/mL. What is the mass percentage of ammonia in the solution?

**16.153** What is the freezing point of 0.92  $M$  aqueous acetic acid? The density of this solution is 1.008 g/cm<sup>3</sup>.

**16.154** What is the freezing point of 0.87  $M$  aqueous ammonia? The density of this solution is 0.992 g/cm<sup>3</sup>.

**16.155** A chemist needs a buffer with pH 4.35. How many milliliters of pure acetic acid (density = 1.049 g/mL) must be added to 465 mL of 0.0941  $M$  NaOH solution to obtain such a buffer?

**16.156** A chemist needs a buffer with pH 3.50. How many milliliters of pure formic acid (density = 1.220 g/mL) must be added to 375 mL of 0.0857  $M$  NaOH solution to obtain such a buffer?

**16.157** Weak base B has a  $\text{p}K_b$  of 6.78 and weak acid HA has a  $\text{p}K_a$  of 5.12.

- Which is the stronger base, B or  $\text{A}^-$ ?
- Which is the stronger acid, HA or  $\text{BH}^+$ ?
- Consider the following reaction:

Based on the information about the acid/base strengths for the species in this reaction, is this reaction favored to proceed more to the right or more to the left?

Why?

- d** An aqueous solution is made in which the concentration of weak base  $B$  is one half the concentration of its acidic salt,  $BHCl$ , where  $BH^+$  is the conjugate weak acid of  $B$ . Calculate the pH of the solution.
- e** An aqueous solution is made in which the concentration of weak acid  $HA$  is twice the concentration of the sodium salt of the weak acid,  $NaA$ . Calculate the pH of the solution.

**f** Assume the conjugate pairs  $B/BH^+$  and  $HA/A^-$  are capable of being used as color-based end point indicators in acid–base titrations, where  $B$  is the base form indicator and  $BH^+$  is the acid form indicator, and  $HA$  is the acid form indicator and  $A^-$  is the base form indicator. Select the indicator pair that would be best to use in each of the following titrations:

- (1) Titration of a strong acid with a strong base.  
(i)  $B/BH^+$             (ii)  $HA/A^-$
- (2) Titration of a weak base with a strong acid.  
(i)  $B/BH^+$             (ii)  $HA/A^-$

## CONTENTS AND CONCEPTS

**Solubility Equilibria**

In these sections, we look at the equilibria of slightly soluble (or nearly insoluble) ionic compounds. We first show how you can determine their equilibrium constants. Then we show how to use these equilibrium constants to answer questions about solubility and precipitation.

**17.1** The Solubility Product Constant

**17.2** Solubility and the Common-Ion Effect

**17.3** Precipitation Calculations

**17.4** Effect of pH on Solubility

**Complex-Ion Equilibria**

Metal ions, especially transition-metal ions, form coordinate covalent bonds with molecules or anions that have lone pairs of electrons. The result is a *complex ion*. In these sections, we look at the formation of complex ions and their effect on solubility of slightly soluble ionic compounds.

**17.5** Complex-Ion Formation

**17.6** Complex Ions and Solubility

**An Application of Solubility Equilibria**

In this last section, we look at the sulfide scheme of *qualitative analysis* to illustrate concepts of solubility, buffers, and complex-ion equilibria.

**17.7** Qualitative Analysis of Metal Ions

Many natural processes depend on the precipitation or the dissolving of a slightly soluble salt. For example, caves form in limestone (calcium carbonate) over thousands of years as groundwater seeps through cracks, dissolving out cavities in the rock. Kidney stones form when salts such as calcium phosphate or calcium oxalate slowly precipitate in the kidney (Figure 17.1). Poisoning by oxalic acid is also explained by the precipitation of the calcium salt. If oxalic acid is accidentally ingested, the oxalate-ion concentration in the blood may increase sufficiently to precipitate calcium oxalate. Calcium ion, which is needed for proper muscle control, is then removed from the blood, and muscle tissues go into spasm.

To understand such phenomena quantitatively, you must be able to solve problems in solubility equilibria. Calcium oxalate kidney stones form when the concentrations of calcium ion and oxalate ion are sufficiently great. What is the relationship between the concentrations of ions and the solubility of a salt? What is the minimum concentration of oxalate ion that gives a precipitate of the calcium salt from a 0.0025 M solution of  $\text{Ca}^{2+}$  (the approximate concentration of calcium ion in blood plasma)? What is the effect of pH on the solubility of this salt? We will look at questions such as these in this chapter.

## ► Solubility Equilibria

To deal quantitatively with an equilibrium, you must know the equilibrium constant. In the next section, we will look at the equilibria of slightly soluble (or nearly insoluble) ionic compounds and show how you can determine their equilibrium constants. Once you find these values for various ionic compounds, you can use them to answer questions about solubility or precipitation.

### 17.1 The Solubility Product Constant

When an ionic compound is dissolved in water, it usually goes into solution as the ions. When an excess of a slightly soluble ionic compound is mixed with water, an equilibrium occurs between the solid compound and the ions in the saturated solution. For the salt calcium oxalate,  $\text{CaC}_2\text{O}_4$ , you have the following equilibrium:

The equilibrium constant for this solubility process is called the *solubility product constant* of  $\text{CaC}_2\text{O}_4$ . It is written

$$K_{sp} = [\text{Ca}^{2+}][\text{C}_2\text{O}_4^{2-}]$$

Remember from the discussion in Section 14.3 that because the concentration of solid is essentially constant that its concentration is included in  $K_{sp}$ , so it does not occur in the expression on the right.

In general, the **solubility product constant ( $K_{sp}$ )** is the equilibrium constant for the solubility equilibrium of a slightly soluble (or nearly insoluble) ionic compound. It equals the product of the equilibrium concentrations of the ions in the compound, each concentration raised to a power equal to the number of such ions in the formula of the compound. Like any equilibrium constant,  $K_{sp}$  depends on the temperature, but at a given temperature it has a constant value for various concentrations of the ions. ►

Lead(II) iodide,  $\text{PbI}_2$ , is another slightly soluble salt. The equilibrium in water is

and the expression for the equilibrium constant, or solubility product constant, is

$$K_{sp} = [\text{Pb}^{2+}][\text{I}^{-}]^2$$

Mike Dobe/Alamy

**Figure 17.1** ▲

**A kidney stone** Kidney stones are usually calcium oxalate, or possibly calcium phosphate, that precipitates as a crystalline mass. Calcium oxalate and calcium phosphate are white, but additional substances can color the kidney stones.

An ionic equilibrium is affected to a small extent by the presence of ions not directly involved in the equilibrium. We will ignore this effect here.

**Example 17.1 Writing Solubility Product Expressions****Gaining Mastery Toolbox****Critical Concept 17.1**

When an excess of a slightly soluble ionic solid exists in a water solution, an equilibrium occurs between the solid and its ions in solution.

**Solution Essentials:**

- Solubility product constant,  $K_{sp}$
- Equilibrium constant,  $K_c$
- Molar concentration
- Solubility rules

Write the solubility product expressions for the following salts: a. AgCl; b. Hg<sub>2</sub>Cl<sub>2</sub>; c. Pb<sub>3</sub>(AsO<sub>4</sub>)<sub>2</sub>.

**Problem Strategy** The equilibrium constant for a slightly soluble ionic compound is simply the product of the concentrations of the ions, each raised to a power equal to the number of such ions in the formula of the compound.

**Solution** The equilibria and solubility product expressions are

Note that the mercury(I) ion is Hg<sub>2</sub><sup>2+</sup>. (Mercury also has salts with the mercury(II) ion, Hg<sup>2+</sup>.)

**Answer Check** Make sure that you have the correct formula of the compound and that you understand the ions that are present. For example, Hg<sub>2</sub>Cl<sub>2</sub> is made up of the ions Hg<sub>2</sub><sup>2+</sup> and Cl<sup>-</sup> (not Hg<sup>+</sup> and Cl<sup>-</sup>).

**Exercise 17.1** Give solubility product expressions for the following: a. barium sulfate; b. iron(III) hydroxide; c. calcium phosphate.

See Problems 17.27 and 17.28.

The solubility product constant,  $K_{sp}$ , of a slightly soluble ionic compound is expressed in terms of the molar concentrations of ions in the saturated solution. These ion concentrations are in turn related to the *molar solubility* of the ionic compound, which is the moles of compound that dissolve to give a liter of saturated solution. The next two examples show how to determine the solubility product constant from the solubility of a slightly soluble ionic compound.

**Example 17.2 Calculating  $K_{sp}$  from the Solubility (Simple Example)****Gaining Mastery Toolbox****Critical Concept 17.2**

You obtain the solubility product constant,  $K_{sp}$ , of a slightly soluble compound from the molar concentrations of the compound's ions in solution; these ion concentrations can be related to the molar solubility of the compound.

**Solution Essentials:**

- Solubility product constant,  $K_{sp}$
- Molar solubility
- Equilibrium constant,  $K_c$
- Molar concentration

A liter of a solution saturated at 25°C with calcium oxalate, CaC<sub>2</sub>O<sub>4</sub>, is evaporated to dryness, giving a 0.0061-g residue of CaC<sub>2</sub>O<sub>4</sub>. Calculate the solubility product constant for this salt at 25°C.

**Problem Strategy** The grams of residue from a liter of saturated solution equals the solubility in grams per liter. Convert this to molar solubility (solubility in moles per liter). Then follow the steps similar to those for an equilibrium calculation: set up a table of ion concentrations (starting, change, and equilibrium) and calculate  $K_{sp}$  from the concentrations. The starting concentrations are those before any solid has dissolved (=0), and the change values are obtained from the molar solubility.

**Solution** The solubility of calcium oxalate is 0.0061 g/L of *solution*, and the formula mass of CaC<sub>2</sub>O<sub>4</sub> is 128 amu. Convert grams per liter to moles per liter:

$$\begin{aligned} \text{Molar solubility of CaC}_2\text{O}_4 &= 0.0061 \text{ g CaC}_2\text{O}_4/\text{L} \times \frac{1 \text{ mol CaC}_2\text{O}_4}{128 \text{ g CaC}_2\text{O}_4} \\ &= 4.8 \times 10^{-5} \text{ mol CaC}_2\text{O}_4/\text{L} \end{aligned}$$

Now look at the equilibrium problem.

**Step 1:** Suppose you mix solid CaC<sub>2</sub>O<sub>4</sub> in a liter of solution. Of this solid,  $4.8 \times 10^{-5}$  mol will dissolve to form  $4.8 \times 10^{-5}$  mol of each ion. The results are summarized in the following table. (Because the concentration of the solid does not appear in  $K_{sp}$ , we do not include it in the table.)

(continued)

**Example 17.2** (continued)

Concentration (M)	$\text{CaC}_2\text{O}_4(\text{s}) \rightleftharpoons \text{Ca}^{2+}(\text{aq})$	+	$\text{C}_2\text{O}_4^{2-}(\text{aq})$
Starting	0		0
Change	$+4.8 \times 10^{-5}$		$+4.8 \times 10^{-5}$
Equilibrium	$4.8 \times 10^{-5}$		$4.8 \times 10^{-5}$

**Step 2:** You now substitute into the equilibrium-constant equation:

$$K_{sp} = [\text{Ca}^{2+}][\text{C}_2\text{O}_4^{2-}] = (4.8 \times 10^{-5})(4.8 \times 10^{-5}) = 2.3 \times 10^{-9}$$

**Answer Check** Often, the most effective way to check your work is to invert the problem, using your answer to calculate the information given in the problem statement; the actual steps often involve different operations. Here, you would first calculate the ion concentrations by taking the square root of the  $K_{sp}$  that you obtained. This ion concentration is, in this case, equal to the molar solubility. Multiplying the molar solubility by the formula mass gives the solubility of the compound, which should match the value given in the problem.

**Exercise 17.2** Silver ion may be recovered from used photographic fixing solution by precipitating it as silver chloride. The solubility of silver chloride is  $1.9 \times 10^{-3}$  g/L. Calculate  $K_{sp}$ . See Problems 17.29 and 17.30.

**Example 17.3** Calculating  $K_{sp}$  from the Solubility (More Complicated Example)**Gaining Mastery Toolbox****Critical Concept 17.3**

The number of moles of ion formed when one mole of slightly soluble compound dissolves affects the calculation of  $K_{sp}$  from molar solubility in two places: the molar concentration of ion (which is some multiple of molar solubility) and its exponent in the expression for the solubility product.

**Solution Essentials:**

- Solubility product constant,  $K_{sp}$
- Molar solubility
- Equilibrium constant,  $K_c$
- Molar concentration

By experiment, it is found that  $1.2 \times 10^{-3}$  mol of lead(II) iodide,  $\text{PbI}_2$ , dissolves in 1 L of aqueous solution at 25°C. What is the solubility product constant at this temperature?

**Problem Strategy** This is similar to the previous example, except that every mole of the compound ( $\text{PbI}_2$ ) dissolves to form *two* moles of the anion ( $\text{I}^-$ ). This difference affects the calculation in two places: it affects the molar concentration of the ion (the molar concentration of the anion is *twice* that of the molar solubility), and it affects the equilibrium-constant expression (which contains the anion concentration *squared*).

**Solution**

**Step 1:** Suppose the solid lead(II) iodide is mixed into 1 L of solution. You find that  $1.2 \times 10^{-3}$  mol dissolves to form  $1.2 \times 10^{-3}$  mol  $\text{Pb}^{2+}$  and  $2 \times (1.2 \times 10^{-3})$  mol  $\text{I}^-$ , as summarized in the following table:

Concentration (M)	$\text{PbI}_2(\text{s}) \rightleftharpoons \text{Pb}^{2+}(\text{aq})$	+	$2\text{I}^-(\text{aq})$
Starting	0		0
Change	$+1.2 \times 10^{-3}$		$+2 \times (1.2 \times 10^{-3})$
Equilibrium	$1.2 \times 10^{-3}$		$2 \times (1.2 \times 10^{-3})$

**Step 2:** You substitute into the equilibrium-constant equation:

$$K_{sp} = [\text{Pb}^{2+}][\text{I}^-]^2 = (1.2 \times 10^{-3}) \times (2 \times 1.2 \times 10^{-3})^2 = 6.9 \times 10^{-9}$$

**Answer Check** As in the previous example, an effective check is simply to reverse the calculation to see whether you do get the value given in the problem statement. Suppose you let the molar solubility be  $x$  (which is the value given in the problem statement). Then  $x$  is the concentration of  $\text{Pb}^{2+}$ , and  $2x$  is the concentration of  $\text{I}^-$  (because there are twice as many  $\text{I}^-$  ions as  $\text{Pb}^{2+}$  ions). Thus,  $K_{sp} = [\text{Pb}^{2+}][\text{I}^-]^2 = x \times (2x)^2 = 4x^3$ , and

$$x = \sqrt[3]{K_{sp}/4} = \sqrt[3]{6.9 \times 10^{-9}/4} = 1.2 \times 10^{-3}$$

© Cengage Learning

(continued)

**Example 17.3** (continued)

**Exercise 17.3** Lead(II) arsenate,  $\text{Pb}_3(\text{AsO}_4)_2$ , has been used as an insecticide. It is only slightly soluble in water. If the solubility is  $3.0 \times 10^{-5}$  g/L, what is the solubility product constant? Assume that the solubility equilibrium is the only important one.

See Problems 17.31 and 17.32.

Table 17.1 lists the solubility product constants for various ionic compounds. If the solubility product constant is known, the solubility of the compound can be calculated.

**Table 17.1** Solubility Product Constants,  $K_{sp}$ , at 25°C

Substance	Formula	$K_{sp}$	Substance	Formula	$K_{sp}$
Aluminum hydroxide	$\text{Al}(\text{OH})_3$	$4.6 \times 10^{-33}$	Lead(II) sulfide	$\text{PbS}$	$2.5 \times 10^{-27}$
Barium chromate	$\text{BaCrO}_4$	$1.2 \times 10^{-10}$	Magnesium arsenate	$\text{Mg}_3(\text{AsO}_4)_2$	$2 \times 10^{-20}$
Barium fluoride	$\text{BaF}_2$	$1.0 \times 10^{-6}$	Magnesium carbonate	$\text{MgCO}_3$	$1.0 \times 10^{-5}$
Barium sulfate	$\text{BaSO}_4$	$1.1 \times 10^{-10}$	Magnesium hydroxide	$\text{Mg}(\text{OH})_2$	$1.8 \times 10^{-11}$
Cadmium oxalate	$\text{CdC}_2\text{O}_4$	$1.5 \times 10^{-8}$	Magnesium oxalate	$\text{MgC}_2\text{O}_4$	$8.5 \times 10^{-5}$
Cadmium sulfide	$\text{CdS}$	$8 \times 10^{-27}$	Manganese(II) sulfide	$\text{MnS}$	$2.5 \times 10^{-10}$
Calcium carbonate	$\text{CaCO}_3$	$3.8 \times 10^{-9}$	Mercury(I) chloride	$\text{Hg}_2\text{Cl}_2$	$1.3 \times 10^{-18}$
Calcium fluoride	$\text{CaF}_2$	$3.4 \times 10^{-11}$	Mercury(II) sulfide	$\text{HgS}$	$1.6 \times 10^{-52}$

**Example 17.4** Calculating the Solubility from  $K_{sp}$ **Gaining Mastery Toolbox****Critical Concept 17.4**

If you let the molar solubility of a slightly soluble compound be  $x$ , you can write the molar concentrations of ions formed in terms of  $x$ , and from these you can write the equation involving  $K_{sp}$ . Solving this equation gives you the molar solubility.

**Solution Essentials:**

- Solubility product constant,  $K_{sp}$
- Molar solubility
- Equilibrium constant,  $K_c$
- Molar concentration

The mineral fluorite is calcium fluoride,  $\text{CaF}_2$ . Calculate the solubility (in grams per liter) of calcium fluoride in water from the solubility product constant ( $3.4 \times 10^{-11}$ ).

**Problem Strategy** This problem is the reverse of the preceding ones; instead of finding  $K_{sp}$  from the solubility, here you calculate solubility from the  $K_{sp}$ . You follow the three steps for equilibrium problems, but since the molar solubility is not immediately known, you assign it the value  $x$ . For Step 1, you obtain the concentration of each ion by multiplying  $x$  by the coefficient of the ion in the chemical equation. In Step 2, you obtain  $K_{sp}$  as a cubic in  $x$ . In Step 3, you solve the equilibrium-constant equation for  $x$ , which will involve taking a cube root.

**Solution**

**Step 1:** Let  $x$  be the molar solubility of  $\text{CaF}_2$ . When solid  $\text{CaF}_2$  is mixed into a liter of solution,  $x$  mol dissolves, forming  $x$  mol  $\text{Ca}^{2+}$  and  $2x$  mol  $\text{F}^-$ .

Starting	0	0
Change	+ $x$	+ $2x$
Equilibrium	$x$	$2x$

**Step 2:** You substitute into the equilibrium-constant equation.

$$\begin{aligned} [\text{Ca}^{2+}][\text{F}^-]^2 &= K_{sp} \\ (x)(2x)^2 &= 3.4 \times 10^{-11} \\ 4x^3 &= 3.4 \times 10^{-11} \end{aligned}$$

**Step 3:** You now solve for  $x$ .

$$x = \sqrt[3]{\frac{3.4 \times 10^{-11}}{4}} = 2.0 \times 10^{-4}$$

Mark A. Schneider/Science Source

The mineral fluorite ( $\text{CaF}_2$ )

The molar solubility is  $2.0 \times 10^{-4}$  mol  $\text{CaF}_2$  per liter. To get the solubility in grams per liter, you convert, using the molar mass of  $\text{CaF}_2$  (78.1 g/mol).

$$\text{Solubility} = 2.0 \times 10^{-4} \text{ mol CaF}_2/\text{L} \times \frac{78.1 \text{ g CaF}_2}{1 \text{ mol CaF}_2} = 1.6 \times 10^{-2} \text{ g CaF}_2/\text{L}$$

**Answer Check** As a quick check of your work, calculate  $K_{sp}$  for  $\text{CaF}_2$  from the values you obtained for the molar concentrations of ions:

$$\begin{aligned} [\text{Ca}^{2+}] &= x = 2.0 \times 10^{-4} \\ [\text{F}^-] &= 2x = 4.0 \times 10^{-4} \\ K_{sp} &= [\text{Ca}^{2+}][\text{F}^-]^2 = (2.0 \times 10^{-4})(4.0 \times 10^{-4})^2 = 3.2 \times 10^{-11} \end{aligned}$$

Note the agreement (within computational error) with the value given in the problem ( $3.4 \times 10^{-11}$ ).

**Exercise 17.4** Anhydrite is a calcium sulfate mineral deposited when seawater evaporates. What is the solubility of calcium sulfate, in grams per liter? Table 17.1 gives the solubility product constant for calcium sulfate.

See Problems 17.35, 17.36, 17.37, and 17.38.

These examples illustrate the relationship between the solubility of a slightly soluble ionic compound in pure water and its solubility product constant. In the next section, you will see how the solubility product constant can be used to calculate the solubility in the presence of other ions.  $K_{sp}$  is also useful in deciding whether to expect precipitation under given conditions.

Before leaving this section, we need to add a note of caution. We have calculated the solubility product of calcium oxalate,  $\text{CaC}_2\text{O}_4$ , and the solubility of calcium fluoride,  $\text{CaF}_2$ , assuming that only the solubility equilibrium is important. You need to be aware, however, that hydrolysis of the anion can be important, too, particularly if the anion is quite basic, which will be the case if the conjugate acid is rather weak. In the two examples given in this section, hydrolysis is relatively unimportant. (You may want to look at Problem 17.117, which examines this issue.)

### CONCEPT CHECK 17.1

Lead compounds have been used as paint pigments, but because the lead(II) ion is toxic, the use of lead paints in homes is now prohibited. Which of the following lead(II) compounds would yield the greatest number of lead(II) ions when added to the same quantity of water (assuming that some undissolved solid always remains):  $\text{PbCrO}_4$ ,  $\text{PbSO}_4$ , or  $\text{PbS}$ ?

## 17.2 Solubility and the Common-Ion Effect

The importance of the solubility product constant becomes apparent when you consider the solubility of one salt in the solution of another salt having the same cation or anion. For example, suppose you wish to know the solubility of calcium oxalate in a solution of calcium chloride. Each salt contributes the same cation ( $\text{Ca}^{2+}$ ). The effect of the calcium ion provided by the calcium chloride is to make calcium oxalate less soluble than it would be in pure water.

You can explain this decrease in solubility in terms of Le Châtelier's principle. Suppose you first mix crystals of calcium oxalate in a quantity of pure water to establish the equilibrium:

Now imagine that you add some calcium chloride. Calcium chloride is a soluble salt, so it dissolves to give an increase in calcium-ion concentration. You can regard this increase as a stress on the original equilibrium. According to Le Châtelier's principle, the ions will react to remove some of the added calcium ion.

In other words, some calcium oxalate precipitates from the solution. The solution now contains less calcium oxalate. You conclude that calcium oxalate is less soluble in a solution of calcium chloride than in pure water.

A solution of soluble calcium chloride has an ion *in common* with the slightly soluble calcium oxalate. The decrease in solubility of calcium oxalate in a solution of calcium chloride is an example of the *common-ion effect* (first discussed in Section 16.5). In general, any ionic equilibrium is affected by a substance producing an ion involved in the equilibrium, as you would predict from Le Châtelier's principle. Figure 17.2 illustrates the principle of the common-ion effect for lead(II) chromate,  $\text{PbCrO}_4$ , which is only slightly soluble in water at 25°C. When the very soluble  $\text{Pb}(\text{NO}_3)_2$  is added to a saturated solution of  $\text{PbCrO}_4$ , the concentration of the common ion,  $\text{Pb}^{2+}$ , increases and  $\text{PbCrO}_4$  precipitates. The equilibrium is

The next example shows how you can calculate the solubility of a slightly soluble salt in a solution containing a substance with a common ion.

© Cengage Learning

**Figure 17.2** ▲ **Demonstration of the common-ion effect** When the experimenter adds lead(II) nitrate solution (colorless) from the dropper to the saturated solution of lead(II) chromate (pale yellow), a yellow precipitate of lead chromate forms.

**Example 17.5 Calculating the Solubility of a Slightly Soluble Salt in a Solution of a Common Ion****Gaining Mastery Toolbox****Critical Concept 17.5**

The solubility of an ionic compound is less in a solution that contains an ion also present in the compound than it is in pure water. Note that the equilibrium concentration of this ion equals the initial concentration of the ion plus whatever concentration is contributed by the dissolution of the compound.

**Solution Essentials:**

- Solubility product constant,  $K_{sp}$
- Molar solubility
- Common-ion effect
- Le Châtelier's principle
- Equilibrium constant,  $K_c$
- Molar concentration

What is the molar solubility of calcium oxalate in 0.15  $M$  calcium chloride? Compare this molar solubility with that found earlier (Example 17.2) for  $\text{CaC}_2\text{O}_4$  in pure water ( $4.8 \times 10^{-5} M$ ). The solubility product constant for calcium oxalate is  $2.3 \times 10^{-9}$ .

**Problem Strategy** The two salts have a common ion ( $\text{Ca}^{2+}$ ): one salt ( $\text{CaCl}_2$ ) is soluble and provides  $\text{Ca}^{2+}$  ion that suppresses the solubility of the slightly soluble salt ( $\text{CaC}_2\text{O}_4$ ). You solve the solubility equilibrium for the slightly soluble salt, noting that when you set up the concentration table you have a starting concentration of  $\text{Ca}^{2+}$  ion from  $\text{CaCl}_2$ . The equilibrium-constant equation you obtain is a quadratic, which you can reduce to a linear equation using the same approximation used in Chapter 16; you assume  $x$  is small compared with the number you add it to. (That is, the starting  $\text{Ca}^{2+}$  concentration is not much affected by the dissolution of the slightly soluble salt.) The value of  $x$  equals the molar solubility of the slightly soluble salt in the presence of the common ion.

**Solution**

**Step 1:** Suppose solid  $\text{CaC}_2\text{O}_4$  is mixed into 1 L of 0.15  $M$   $\text{CaCl}_2$  and that the molar solubility of the  $\text{CaC}_2\text{O}_4$  is  $x M$ . At the start (before  $\text{CaC}_2\text{O}_4$  dissolves), there is 0.15 mol  $\text{Ca}^{2+}$  in the solution. Of the solid  $\text{CaC}_2\text{O}_4$ ,  $x$  mol dissolves to give  $x$  mol of additional  $\text{Ca}^{2+}$  and  $x$  mol  $\text{C}_2\text{O}_4^{2-}$ . The following table summarizes these results:

Concentration (M)	$\text{CaC}_2\text{O}_4(\text{s})$	$\rightleftharpoons$	$\text{Ca}^{2+}(\text{aq})$	$+$	$\text{C}_2\text{O}_4^{2-}(\text{aq})$
Starting			0.15		0
Change			$+x$		$+x$
Equilibrium			$0.15 + x$		$x$

**Step 2:** You substitute into the equilibrium-constant equation:

$$[\text{Ca}^{2+}][\text{C}_2\text{O}_4^{2-}] = K_{sp}$$

$$(0.15 + x)x = 2.3 \times 10^{-9}$$

**Step 3:** Now rearrange this equation to give

$$x = \frac{2.3 \times 10^{-9}}{0.15 + x}$$

Because calcium oxalate is only slightly soluble, you might expect  $x$  to be negligible compared with 0.15. In that case,

$$0.15 + x \approx 0.15$$

and the previous equation becomes

$$x \approx \frac{2.3 \times 10^{-9}}{0.15} = 1.5 \times 10^{-8}$$

Note that  $x$  is indeed much smaller than 0.15, so your assumption was correct. Therefore, the molar solubility of calcium oxalate in 0.15  $M$   $\text{CaCl}_2$  is  $1.5 \times 10^{-8} M$ . In pure water, the molar solubility is  $4.8 \times 10^{-5} M$ , which is over **3000 times greater**.

**Answer Check** Calculate  $K_{sp}$  from the calculated molar solubility of calcium oxalate ( $1.5 \times 10^{-8} M$ ). The concentration of  $\text{Ca}^{2+}$  ion is 0.15  $M$  from  $\text{CaCl}_2$  (plus  $1.5 \times 10^{-8} M$  from dissolved calcium oxalate, which is negligible), and the concentration of oxalate ion is  $1.5 \times 10^{-8} M$ . Therefore,

$$K_{sp} = [\text{Ca}^{2+}][\text{C}_2\text{O}_4^{2-}] = (0.15)(1.5 \times 10^{-8}) = 2.3 \times 10^{-9}$$

which agrees with the value given in the problem statement.

**Exercise 17.5** a. Calculate the molar solubility of barium fluoride,  $\text{BaF}_2$ , in water at 25°C. The solubility product constant for  $\text{BaF}_2$  at this temperature is  $1.0 \times 10^{-6}$ .  
b. What is the molar solubility of barium fluoride in 0.15  $M$   $\text{NaF}$  at 25°C? Compare the solubility in this case with that of  $\text{BaF}_2$  in pure water.

See Problems  
17.39, 17.40,  
17.41, and 17.42.

✓ **CONCEPT CHECK 17.2**

Suppose you have equal volumes of saturated solutions of  $\text{NaNO}_3$ ,  $\text{Na}_2\text{SO}_4$ , and  $\text{PbS}$ . Which solution would dissolve the most lead(II) sulfate,  $\text{PbSO}_4$ ?

✓ **CONCEPT CHECK 17.3**

Consider the beaker below, which represents a saturated solution of  $\text{AgCl}(aq)$ . Draw a picture of the solution in the beaker after the addition of  $\text{NaCl}(aq)$ .

### 17.3 Precipitation Calculations

In the chapter opening, we mentioned that calcium oxalate precipitates to form kidney stones. The same salt would precipitate in the body if oxalic acid (a poison) were accidentally ingested, because  $\text{Ca}^{2+}$  ion is present in the blood. (See Figure 17.3 for another example of a precipitation.) To understand processes such as these, you must understand the conditions under which precipitation occurs. Precipitation is merely another way of looking at a solubility equilibrium. Rather than ask how much of a substance will dissolve in a solution, you ask: Will precipitation occur for given starting ion concentrations?

**Figure 17.3** ▲

**Formation of a precipitate** Silver chromate,  $\text{Ag}_2\text{CrO}_4$ , precipitates when a demonstrator adds aqueous potassium chromate,  $\text{K}_2\text{CrO}_4(aq)$ , to aqueous silver nitrate,  $\text{AgNO}_3(aq)$ .

© Cengage Learning

#### Criterion for Precipitation

The question just asked can be stated more generally: Given the concentrations of substances in a reaction mixture, will the reaction go in the forward or the reverse direction? To answer this, you evaluate the *reaction quotient*  $Q_c$  and compare it with the equilibrium constant  $K_c$ . ◀ The reaction quotient has the same form as the equilibrium-constant expression, but the concentrations of substances are not necessarily equilibrium values. Rather, they are concentrations at the start of a reaction. To predict the direction of reaction, you compare  $Q_c$  with  $K_c$ .

If  $Q_c > K_c$ , the reaction should go in the forward direction.

If  $Q_c = K_c$ , the reaction mixture is at equilibrium.

If  $Q_c < K_c$ , the reaction should go in the reverse direction.

Suppose you add lead(II) nitrate,  $\text{Pb}(\text{NO}_3)_2$ , and sodium chloride,  $\text{NaCl}$ , to water to give a solution that is  $0.050\text{ M Pb}^{2+}$  and  $0.10\text{ M Cl}^-$ . Will lead(II) chloride,  $\text{PbCl}_2$ , precipitate? To answer this, you first write the solubility equilibrium.

The reaction quotient has the form of the equilibrium-constant expression, which in this case is the  $K_{sp}$  expression, but the concentrations of the products are starting values, denoted by the subscript  $i$ .

$$Q_c = [\text{Pb}^{2+}]_i [\text{Cl}^-]_i^2$$

Here  $Q_c$  for a solubility reaction is often called the **ion product** (rather than reaction quotient), because it is *the product of ion concentrations in a solution, each concentration raised to a power equal to the number of ions in the formula of the ionic compound*.

To evaluate the ion product  $Q_c$ , you substitute the concentrations of  $\text{Pb}^{2+}$  and  $\text{Cl}^-$  ions in the solution at the start of the reaction. You have  $0.050\text{ M Pb}^{2+}$  and  $0.10\text{ M Cl}^-$ . Substituting, you find that

$$Q_c = (0.050)(0.10)^2 = 5.0 \times 10^{-4}$$

The reaction quotient was discussed in Section 14.5.

$K_{sp}$  for  $\text{PbCl}_2$  is  $1.6 \times 10^{-5}$  (Table 17.1), so  $Q_c$  is greater than  $K_{sp}$ . Therefore, the reaction goes in the reverse direction. That is,

In other words,  $\text{Pb}^{2+}$  and  $\text{Cl}^{-}$  react to precipitate  $\text{PbCl}_2$ . As precipitation occurs, the ion concentrations, and hence the ion product, decrease. Precipitation ceases when the ion product equals  $K_{sp}$ . The reaction mixture is then at equilibrium.

We can summarize our conclusions in terms of the following criterion for precipitation.

Precipitation is expected to occur if the ion product for a solubility reaction is greater than  $K_{sp}$ . If the ion product is less than  $K_{sp}$ , precipitation will not occur (the solution is unsaturated with respect to the ionic compound). If the ion product equals  $K_{sp}$ , the reaction is at equilibrium (the solution is saturated with the ionic compound). ▶

Precipitation may not occur even though the ion product has been exceeded. In such a case, the solution is supersaturated. Usually a small crystal forms after a time, and then precipitation occurs rapidly.

### Example 17.6 Predicting Whether Precipitation Will Occur (Given Ion Concentrations)

#### Gaining Mastery Toolbox

##### Critical Concept 17.6

Precipitation is expected to occur when you mix two solutions and the ion product for the precipitation reaction exceeds the solubility product.

##### Solution Essentials:

- Solubility product constant,  $K_{sp}$
- Molar solubility
- Reaction quotient
- Equilibrium constant,  $K_c$
- Molar concentration

The concentration of calcium ion in blood plasma is  $0.0025 M$ . If the concentration of oxalate ion is  $1.0 \times 10^{-7} M$ , do you expect calcium oxalate to precipitate?  $K_{sp}$  for calcium oxalate is  $2.3 \times 10^{-9}$ .

**Problem Strategy** Precipitation is simply another way of looking at solubility equilibrium.

Going to the right, calcium oxalate dissolves, but going to the left,  $\text{Ca}^{2+}$  and  $\text{C}_2\text{O}_4^{2-}$  react to precipitate calcium oxalate. The reaction quotient,  $Q_c$ , for this equation as written is the ion product  $[\text{Ca}^{2+}]_i[\text{C}_2\text{O}_4^{2-}]_i$ . This ion product decreases as precipitation occurs (and the ion concentrations decrease). As the reaction approaches equilibrium, it approaches the equilibrium constant (the solubility product)  $K_{sp}$ . This means that  $Q_c$  should be greater than  $K_{sp}$  for precipitation to occur; otherwise, precipitation cannot occur. Thus, you calculate  $Q_c$  and compare it with  $K_{sp}$ .

**Solution** The ion product for calcium oxalate is

$$\text{Ion product} = [\text{Ca}^{2+}]_i[\text{C}_2\text{O}_4^{2-}]_i = (0.0025) \times (1.0 \times 10^{-7}) = 2.5 \times 10^{-10}$$

This value is smaller than the solubility product constant, so **you do not expect precipitation to occur**.

**Answer Check** Be sure that you have the correct expression for the reaction quotient and that you correctly compare the reaction quotient to the solubility product.

**Exercise 17.6** Anhydrite is a mineral composed of  $\text{CaSO}_4$  (calcium sulfate). An inland lake has  $\text{Ca}^{2+}$  and  $\text{SO}_4^{2-}$  concentrations of  $0.0052 M$  and  $0.0041 M$ , respectively. If these concentrations were doubled by evaporation, would you expect calcium sulfate to precipitate?

See Problems 17.47 and 17.48.

Precipitation is an important industrial and laboratory process. Figure 17.4 shows the vats used to precipitate magnesium ion from seawater, which is a source of magnesium metal. The following example is a typical problem in precipitation. You are given the volumes and concentrations of two solutions and asked whether a precipitate will form when the solutions are mixed.

**Example 17.7 Predicting Whether Precipitation Will Occur (Given Solution Volumes and Concentrations)****Gaining Mastery Toolbox****Critical Concept 17.7**

To see if precipitation is expected, you need the ion product, which is given in terms of concentrations of ions. You obtain these concentrations from the moles of ions added and the total volume of the solution.

**Solution Essentials:**

- Solubility product constant,  $K_{sp}$
- Molar solubility
- Reaction quotient
- Equilibrium constant,  $K_c$
- Molar concentration

Sulfate ion,  $\text{SO}_4^{2-}$ , in solution is often determined quantitatively by precipitating it as barium sulfate,  $\text{BaSO}_4$ . The sulfate ion may have been formed from a sulfur compound. Analysis for the amount of sulfate ion then indicates the percentage of sulfur in the compound. Is a precipitate expected to form when 50.0 mL of 0.0010  $M$   $\text{BaCl}_2$  is added to 50.0 mL of 0.00010  $M$   $\text{Na}_2\text{SO}_4$ ? The solubility product constant for barium sulfate is  $1.1 \times 10^{-10}$ . Assume that the total volume of solution, after mixing, equals the sum of the volumes of the separate solutions.

**Problem Strategy** You need to calculate  $Q_c$ , the ion product, to compare it with  $K_{sp}$ , the solubility product. For  $Q_c$ , you need to obtain the concentrations of ions in the solution just after mixing, but before precipitation, if any occurs. First, calculate the moles of each ion added. Then, using the total volume of solution (assumed to equal the sum of the two added solutions), calculate the molar concentration of each ion present. Finally, calculate  $Q_c$  and compare it with  $K_{sp}$ .

**Solution** The molar amount of  $\text{Ba}^{2+}$  present in 50.0 mL (0.0500 L) of 0.0010  $M$   $\text{BaCl}_2$  is

$$\text{Amount of Ba}^{2+} = \frac{0.0010 \text{ mol Ba}^{2+}}{1 \text{ L soln}} \times 0.050 \text{ L soln} = 5.0 \times 10^{-5} \text{ mol Ba}^{2+}$$

The molar concentration of  $\text{Ba}^{2+}$  in the total solution equals the molar amount of  $\text{Ba}^{2+}$  divided by the total volume (0.0500 L  $\text{BaCl}_2$  + 0.0500 L  $\text{Na}_2\text{SO}_4$  = 0.1000 L).

$$[\text{Ba}^{2+}] = \frac{5.0 \times 10^{-5} \text{ mol}}{0.1000 \text{ L soln}} = 5.0 \times 10^{-4} M$$

Similarly, you find  $[\text{SO}_4^{2-}] = 5.0 \times 10^{-5} M$  (Try the calculations for  $\text{SO}_4^{2-}$ .) The ion product is

$$\begin{aligned} Q_c &= [\text{Ba}^{2+}]_i [\text{SO}_4^{2-}]_i \\ &= (5.0 \times 10^{-4}) \times (5.0 \times 10^{-5}) \\ &= 2.5 \times 10^{-8} \end{aligned}$$

Because the ion product is greater than the solubility product constant ( $1.1 \times 10^{-10}$ ), **you expect barium sulfate to precipitate.**

© ISM/Phototake

**An X-ray photograph of a patient's colon (large intestine)** The colon shows up after the patient has ingested an aqueous suspension of barium sulfate, which is opaque to X rays. Even though free barium ion is toxic, barium sulfate is harmless because it is so insoluble. (Color enhanced by computer for contrast.)

**Answer Check** Note that you calculate the *amount* of barium ion added using the volume of barium chloride solution added (0.050 L). Similarly, you calculate the amount of sulfate ion present from the *initial* volume of sodium sulfate (0.050 L). But to calculate the *concentrations* of these ions when both solutions are present together, you use the total volume of the two solutions (0.1000 L).

**Exercise 17.7** A solution of 0.00016  $M$  lead(II) nitrate,  $\text{Pb}(\text{NO}_3)_2$ , was poured into 456 mL of 0.00023  $M$  sodium sulfate,  $\text{Na}_2\text{SO}_4$ . Would a precipitate of lead(II) sulfate,  $\text{PbSO}_4$ , be expected to form if 255 mL of the lead nitrate solution were added?

See Problems 17.49 and 17.50.

### Fractional Precipitation

**Fractional precipitation** is the technique of separating two or more ions from a solution by adding a reactant that precipitates first one ion, then another, and so forth. For example, suppose a solution is  $0.10\text{ M Ba}^{2+}$  and  $0.10\text{ M Sr}^{2+}$ . As we will show in the following paragraphs, when you slowly add a concentrated solution of potassium chromate,  $\text{K}_2\text{CrO}_4$ , to the solution of  $\text{Ba}^{2+}$  and  $\text{Sr}^{2+}$  ions, barium chromate precipitates first. After most of the  $\text{Ba}^{2+}$  ion has precipitated, strontium chromate begins to come out of solution. It is therefore possible to separate  $\text{Ba}^{2+}$  and  $\text{Sr}^{2+}$  ions from a solution by fractional precipitation using  $\text{K}_2\text{CrO}_4$ .

To understand why  $\text{Ba}^{2+}$  and  $\text{Sr}^{2+}$  ions can be separated in this way, calculate (1) the concentration of  $\text{CrO}_4^{2-}$  necessary to just begin the precipitation of  $\text{BaCrO}_4$ , and (2) the concentration of  $\text{CrO}_4^{2-}$  necessary to just begin the precipitation of  $\text{SrCrO}_4$ . Ignore any volume change in the solution of  $\text{Ba}^{2+}$  and  $\text{Sr}^{2+}$  ions resulting from the addition of the concentrated  $\text{K}_2\text{CrO}_4$  solution. To calculate the  $\text{CrO}_4^{2-}$  concentration when  $\text{BaCrO}_4$  begins to precipitate, you substitute the initial  $\text{Ba}^{2+}$  concentration into the solubility product equation.  $K_{sp}$  for  $\text{BaCrO}_4$  is  $1.2 \times 10^{-10}$ .

$$\begin{aligned} [\text{Ba}^{2+}][\text{CrO}_4^{2-}] &= K_{sp} \quad (\text{for BaCrO}_4) \\ (0.10)[\text{CrO}_4^{2-}] &= 1.2 \times 10^{-10} \\ [\text{CrO}_4^{2-}] &= \frac{1.2 \times 10^{-10}}{0.10} = 1.2 \times 10^{-9}\text{ M} \end{aligned}$$

In the same way, you can calculate the  $\text{CrO}_4^{2-}$  concentration when  $\text{SrCrO}_4$  begins to precipitate.  $K_{sp}$  for  $\text{SrCrO}_4$  is  $3.5 \times 10^{-5}$ .

$$\begin{aligned} [\text{Sr}^{2+}][\text{CrO}_4^{2-}] &= K_{sp} \quad (\text{for SrCrO}_4) \\ (0.10)[\text{CrO}_4^{2-}] &= 3.5 \times 10^{-5} \\ [\text{CrO}_4^{2-}] &= \frac{3.5 \times 10^{-5}}{0.10} = 3.5 \times 10^{-4}\text{ M} \end{aligned}$$

Note that  $\text{BaCrO}_4$  precipitates first, because the  $\text{CrO}_4^{2-}$  concentration necessary to form the  $\text{BaCrO}_4$  precipitate is smaller.

These results reveal that as the solution of  $\text{K}_2\text{CrO}_4$  is slowly added to the solution of  $\text{Ba}^{2+}$  and  $\text{Sr}^{2+}$ , barium chromate begins to precipitate when the  $\text{CrO}_4^{2-}$  concentration reaches  $1.2 \times 10^{-9}\text{ M}$ . Barium chromate continues to precipitate as  $\text{K}_2\text{CrO}_4$  is added. When the concentration of  $\text{CrO}_4^{2-}$  reaches  $3.5 \times 10^{-4}\text{ M}$ , strontium chromate begins to precipitate.

What is the percentage of  $\text{Ba}^{2+}$  ion remaining just as  $\text{SrCrO}_4$  begins to precipitate? First calculate the concentration of  $\text{Ba}^{2+}$  at this point. You write the solubility product equation and substitute  $[\text{CrO}_4^{2-}] = 3.5 \times 10^{-4}$ , the concentration of chromate ion when  $\text{SrCrO}_4$  begins to precipitate.

$$\begin{aligned} [\text{Ba}^{2+}][\text{CrO}_4^{2-}] &= K_{sp} \quad (\text{for BaCrO}_4) \\ [\text{Ba}^{2+}](3.5 \times 10^{-4}) &= 1.2 \times 10^{-10} \\ [\text{Ba}^{2+}] &= \frac{1.2 \times 10^{-10}}{3.5 \times 10^{-4}} = 3.4 \times 10^{-7}\text{ M} \end{aligned}$$

To calculate the percentage of  $\text{Ba}^{2+}$  ion remaining, you divide this concentration of  $\text{Ba}^{2+}$  by the initial concentration ( $0.10\text{ M}$ ) and multiply by 100%.

$$\frac{3.4 \times 10^{-7}}{0.10} \times 100\% = 0.00034\%$$

The percentage of  $\text{Ba}^{2+}$  ion remaining in solution is quite low, so most of the  $\text{Ba}^{2+}$  ion has precipitated by the time  $\text{SrCrO}_4$  begins to precipitate. You conclude that  $\text{Ba}^{2+}$

Figure 17.4 ▲

**Vats for the precipitation of magnesium hydroxide from seawater** Seawater contains magnesium ion (in addition to other ions). When base is added, magnesium hydroxide precipitates. This is the source of magnesium metal.

**Figure 17.5** ▶

Titration of chloride ion by silver nitrate using potassium chromate as an indicator

and  $Sr^{2+}$  can indeed be separated by fractional precipitation. (Another application of fractional precipitation is shown in Figure 17.5.)

### 17.4 Effect of pH on Solubility

In discussing solubility, we have assumed that the only equilibrium of interest was the one between the solid ionic compound and its ions in solution. Sometimes, however, it is necessary to account for other reactions the ions might undergo. For example, if the anion is the conjugate base of a weak acid, the anion reacts with  $H_3O^+$  ion. You should expect the solubility to be affected by pH. We will look into this possibility now.

#### Qualitative Effect of pH

Consider the equilibrium between solid calcium oxalate,  $CaC_2O_4$ , and its ions in aqueous solution:

Because the oxalate ion is conjugate to a weak acid (hydrogen oxalate ion,  $HC_2O_4^-$ ), you would expect it to react with any  $H_3O^+$  ion that is added—say, from a strong acid:

According to Le Châtelier's principle, as  $C_2O_4^{2-}$  ion is removed by reaction with  $H_3O^+$  ion, more calcium oxalate dissolves to replenish some of the  $C_2O_4^{2-}$  ion.

Therefore, you expect calcium oxalate to be more soluble in acidic solution (low pH) than in pure water.

In general, salts of weak acids should be expected to be more soluble in acidic solutions. As an example, consider the process of tooth decay. Bacteria on the teeth produce an acidic medium as a result of the metabolism of sugar. Teeth are normally composed of a calcium phosphate mineral hydroxyapatite, which you can denote as either  $Ca_5(PO_4)_3OH$  or  $3Ca_3(PO_4)_2 \cdot Ca(OH)_2$ . This mineral salt of the

weak acid  $\text{H}_2\text{O}$  (conjugate to  $\text{OH}^-$ ) dissolves in the presence of the acid medium, producing cavities in the teeth. Fluoride toothpastes provide  $\text{F}^-$  ion, which gradually replaces the  $\text{OH}^-$  ion in the teeth to produce fluorapatite,  $\text{Ca}_5(\text{PO}_4)_3\text{F}$  or  $3\text{Ca}_3(\text{PO}_4)_2 \cdot \text{CaF}_2$ , which is much less soluble than hydroxyapatite.

### Example 17.8 Determining the Qualitative Effect of pH on Solubility

#### Gaining Mastery Toolbox

##### Critical Concept 17.8

Salts of weak acids are more soluble in acidic solution. In comparing two salts, the solubility of the one whose anion corresponds to the weaker acid is most affected by the addition of a strong acid.

##### Solution Essentials:

- Solubility equilibrium
- Weak acid
- Acid-ionization constant,  $K_a$
- Le Châtelier's principle

Consider two slightly soluble salts, calcium carbonate and calcium sulfate. Which of these would have its solubility more affected by the addition of  $\text{HCl}$ , a strong acid? Would the solubility of the salt increase or decrease?

**Problem Strategy** A strong acid affects the solubility of a salt of a weak acid by providing hydronium ion that reacts with the anion of the salt in the solution. As the anion is removed by this reaction, more salt dissolves to replenish the anion concentration. You need to determine which salt has the anion corresponding to the weaker acid.

**Solution** Calcium carbonate gives the solubility equilibrium

When a strong acid is added, the hydrogen ion reacts with carbonate ion, because it is conjugate to a weak acid ( $\text{HCO}_3^-$ ).

As carbonate ion is removed, calcium carbonate dissolves. Moreover, the hydrogen carbonate ion itself is removed in further reaction.

Bubbles of carbon dioxide gas appear as more calcium carbonate dissolves.

For calcium sulfate, the corresponding equilibria are

Again, the anion of the insoluble salt is removed by reaction with hydronium ion. You would expect calcium sulfate to become more soluble in strong acid. However,  $\text{HSO}_4^-$  is a much stronger acid than  $\text{HCO}_3^-$ , as you can see by comparing acid-ionization constants. (The values  $K_{a2}$  for  $\text{H}_2\text{CO}_3$  and  $K_a$  for  $\text{HSO}_4^-$  in Table 16.1 are  $4.8 \times 10^{-11}$  and  $1.1 \times 10^{-2}$ , respectively.) **Thus, calcium carbonate is much more soluble in acidic solution, whereas the solubility of calcium sulfate is only slightly affected.**

**Answer Check** Make sure you compare the correct acid-ionization constants. For each salt, you look at the acid corresponding to the anion plus a hydrogen ion. For  $\text{CaCO}_3$ , you look at  $\text{CO}_3^{2-}$  plus  $\text{H}^+$  ( $\text{HCO}_3^-$ , not  $\text{H}_2\text{CO}_3$ ). For  $\text{CaSO}_4$ , you look at  $\text{SO}_4^{2-}$  plus  $\text{H}^+$  ( $\text{HSO}_4^-$ , not  $\text{H}_2\text{SO}_4$ ).

**Exercise 17.8** Which salt would have its solubility more affected by changes in pH, silver chloride or silver cyanide?

See Problems  
17.59 and 17.60.

#### CONCEPT CHECK 17.4

If you add a dilute acidic solution to a mixture containing magnesium oxalate and calcium oxalate, which of the two compounds is more likely to dissolve?

### Separation of Metal Ions by Sulfide Precipitation

Many metal sulfides are insoluble in water but dissolve in acidic solution. The sulfide scheme discussed later, in Section 17.7, uses this change in solubility of the metal sulfides with pH, or hydronium-ion concentration, to separate a mixture of metal ions. Here is how the separation scheme works.

## Environment

A CHEMIST Looks at . . .

## Limestone Caves

On the side of a hill, covered by tall grass and shrubs, the cave entrance might easily be missed. It is barely large enough for a person to enter, even if hunched over, but the space soon expands into a chamber that one can easily stand in. Rock columns rise to an arched ceiling, and there are caverns leading mysteriously away on both sides of the chamber. Limestone caves, like the one described here, which is in Tennessee, dot the landscapes of the eastern and southwestern United States and of Europe and other places as well. Though many limestone caves are inaccessible, a few, like Mammoth Cave in Kentucky and Carlsbad Caverns in New Mexico, are spectacular tourist attractions with multicolored rock draperies and icicle-like *stalactites* hanging from the ceilings of large underground rooms (Figure 17.6). How do such caves form?

Limestone itself formed millions of years ago. Seashells accumulated on ocean floors, and then layers of these shells were subsequently compacted by great pressure from overlying sediment. Later movements of the earth's crust pushed the limestone layers out of the sea, often leaving them well inland.

Seashells and limestone are primarily calcium carbonate. Calcium carbonate is fairly insoluble, as you would expect from its solubility product constant ( $3.8 \times 10^{-9}$ ). But it dissolves readily in acidic solution. Water that has filtered through decomposing vegetation contains carbonic acid, as well as other acids. When such an acidic solution comes into contact with limestone, it carves out caverns. The water is now a solution of calcium hydrogen carbonate.

Galyna Andrushko/Shutterstock.com

Figure 17.6 ▲

**A limestone cave (Carlsbad Caverns, New Mexico)** Such caves are formed by the action of acidic groundwater on limestone deposits. The icicle-like formations (stalagmites and stalactites) in the caves are caused by the reprecipitation of calcium carbonate as carbon dioxide in the solution equilibrates with the surrounding air.

This process is reversible, which you would predict from Le Châtelier's principle. As the calcium hydrogen carbonate solution percolates through holes in the limestone and drips into caverns, water evaporates and carbon dioxide gas escapes; calcium carbonate precipitates as stalactites.

Excess solution drips onto the cavern floor, where calcium carbonate precipitates on upward-growing *stalagmites*. Iron compounds in the solution add yellow and brown colors to the columns of rock. Stalactites and stalagmites grow at the rate of about a centimeter every 300 years.

■ See Problems 17.107 and 17.108.

Consider a solution that is 0.10 M in zinc ion and in lead(II) ion. You add hydrogen sulfide,  $\text{H}_2\text{S}$ , to this solution. Hydrogen sulfide ionizes in water as a diprotic acid:

The ionization forms sulfide ion,  $\text{S}^{2-}$ , which can combine with the metal ions to precipitate the sulfides. Note that by increasing the hydronium-ion concentration, you can reverse both of the previous equilibria and in that way reduce the sulfide-ion concentration. This allows you to control the sulfide-ion concentration of a hydrogen sulfide solution by varying its pH; the lower the pH, the lower the sulfide-ion concentration.

Whether lead(II) sulfide and zinc sulfide precipitate from the hydrogen sulfide solution depends on the solubility product constants of the sulfides and on the

sulfide-ion concentration, which in turn depends on the pH of the solution. Here are the solubility equilibria:

By adjusting the pH of the solution, you adjust the sulfide-ion concentration in order to precipitate the least soluble metal sulfide while maintaining the other metal ion in solution. The solubility product constant of lead(II) sulfide is much smaller than that of zinc sulfide, so it is the least soluble sulfide. When a solution that is 0.10 M in each metal ion and 0.30 M in hydronium ion is saturated with hydrogen sulfide, lead(II) sulfide precipitates, but zinc ion remains in solution. You can now filter off the precipitate of lead(II) sulfide, leaving a solution containing the zinc ion.

## Complex-Ion Equilibria

Many metal ions, especially those of the transition elements, form coordinate covalent bonds with molecules or anions having lone pairs of electrons. For example, the silver ion,  $\text{Ag}^+$ , can react with  $\text{NH}_3$  to form the  $\text{Ag}(\text{NH}_3)_2^+$  ion. The lone pair of electrons on the N atom of  $\text{NH}_3$  forms a coordinate covalent bond to the silver ion to form what is called a complex ion. (See Figure 17.7.)

Note that the metal ion acts as a Lewis acid, and the molecule or anion having the lone pair of electrons acts as a Lewis base. ▶

A **complex ion** is an ion formed from a metal ion with a Lewis base attached to it by a coordinate covalent bond. A complex is a compound containing complex ions. A **ligand** is a Lewis base that bonds to a metal ion to form a complex ion. For example,  $\text{Ag}(\text{NH}_3)_2^+$  is a complex ion formed from the  $\text{Ag}^+$  ion and two  $\text{NH}_3$  molecules. The  $\text{NH}_3$  molecules are the ligands.

## 17.5 Complex-Ion Formation

The aqueous silver ion forms a complex ion with ammonia by reacting with  $\text{NH}_3$  in steps.

When you add these equations, you get the overall equation for the formation of the complex ion  $\text{Ag}(\text{NH}_3)_2^+$ .

The **formation constant**, or **stability constant**,  $K_f$ , of a complex ion is the equilibrium constant for the formation of the complex ion from the aqueous metal ion and the ligands. The formation constant of  $\text{Ag}(\text{NH}_3)_2^+$  is

$$K_f = \frac{[\text{Ag}(\text{NH}_3)_2^+]}{[\text{Ag}^+][\text{NH}_3]^2}$$

The value of  $K_f$  for  $\text{Ag}(\text{NH}_3)_2^+$  is  $1.7 \times 10^7$ . Its large value means that the complex ion is quite stable. When a large amount of  $\text{NH}_3$  is added to a solution of  $\text{Ag}^+$ , you expect most of the  $\text{Ag}^+$  ion to react to form the complex ion. Table 17.2 to the right lists values for the formation constants of some complex ions.

The **dissociation constant** ( $K_d$ ) for a complex ion is the reciprocal, or inverse, value of  $K_f$ . The equation for the dissociation of  $\text{Ag}(\text{NH}_3)_2^+$  is

and its equilibrium constant is

$$K_d = \frac{1}{K_f} = \frac{[\text{Ag}^+][\text{NH}_3]^2}{[\text{Ag}(\text{NH}_3)_2^+]}$$

Figure 17.7 ▲

**Complex ions of nickel(II)** The test tube on the left contains a solution of  $\text{Ni}(\text{H}_2\text{O})_6^{2+}$  ion (green). Adding ammonia to a similar test tube containing this ion, on the right, yields the ammonia complex ion  $\text{Ni}(\text{NH}_3)_6^{2+}$  (purple).

The Lewis concept of acids and bases was discussed in Section 15.3.

Table 17.2 Formation Constants of Complex Ions at 25°C

Complex Ion	$K_f$
$\text{Ag}(\text{CN})_2^-$	$5.6 \times 10^{18}$
$\text{Ag}(\text{NH}_3)_2^+$	$1.7 \times 10^7$
$\text{Ag}(\text{S}_2\text{O}_3)_2^{3-}$	$2.9 \times 10^{13}$
$\text{Cd}(\text{NH}_3)_4^{2+}$	$1.0 \times 10^7$
$\text{Cu}(\text{CN})_2^-$	$1.0 \times 10^{16}$
$\text{Cu}(\text{NH}_3)_4^{2+}$	$4.8 \times 10^{12}$
$\text{Fe}(\text{CN})_6^{4-}$	$1.0 \times 10^{35}$
$\text{Fe}(\text{CN})_6^{3-}$	$9.1 \times 10^{41}$
$\text{Ni}(\text{CN})_4^{2-}$	$1.0 \times 10^{31}$
$\text{Ni}(\text{NH}_3)_6^{2+}$	$5.6 \times 10^8$
$\text{Zn}(\text{NH}_3)_4^{2+}$	$2.9 \times 10^9$
$\text{Zn}(\text{OH})_4^{2-}$	$2.8 \times 10^{15}$

### Equilibrium Calculations with $K_f$

The next example shows how to calculate the concentration of an aqueous metal ion in equilibrium with a complex ion.

#### Example 17.9 Calculating the Concentration of a Metal Ion in Equilibrium with a Complex Ion

##### Gaining Mastery Toolbox

###### Critical Concept 17.9

Many metal ions form complex ions with molecules or ions having lone pairs of electrons with which they can form coordinate covalent bonds.

###### Solution Essentials:

- Complex ion
- Formation constant,  $K_f$ , of a complex ion
- Equilibrium constant,  $K_c$
- Molar concentration
- Stoichiometry

What is the concentration of  $\text{Ag}^+(aq)$  ion in  $0.010\text{ M AgNO}_3$  that is also  $1.00\text{ M NH}_3$ ?  $K_f$  for  $\text{Ag}(\text{NH}_3)_2^+$  ion is  $1.7 \times 10^7$ .

**Problem Strategy** The formation constant for  $\text{Ag}(\text{NH}_3)_2^+$  is large, so silver exists primarily as this ion. This suggests that you do this problem in two parts. First you do the *stoichiometry calculation*, in which you assume that  $\text{Ag}^+(aq)$  reacts completely to form  $\text{Ag}(\text{NH}_3)_2^+(aq)$ . Then you do the *equilibrium calculation*, in which this complex ion dissociates to give a small amount of  $\text{Ag}^+(aq)$ .

**Solution STOICHIOMETRY CALCULATION** In 1 L of solution, you initially have  $0.010\text{ mol Ag}^+(aq)$  from  $\text{AgNO}_3$ . This reacts to give  $0.010\text{ mol Ag}(\text{NH}_3)_2^+$ , leaving  $(1.00 - 2 \times 0.010)\text{ mol NH}_3$ , which equals  $0.98\text{ mol NH}_3$  to two significant figures. You now look at the equilibrium for the dissociation of  $\text{Ag}(\text{NH}_3)_2^+$ .

##### EQUILIBRIUM CALCULATION

**Step 1:** One liter of the solution contains  $0.010\text{ mol Ag}(\text{NH}_3)_2^+$  and  $0.98\text{ mol NH}_3$ . The complex ion dissociates slightly, so that 1 L of solution contains  $x\text{ mol Ag}^+$ . These data are summarized in the following table:

Concentration (M)	$\text{Ag}(\text{NH}_3)_2^+(aq)$	$\rightleftharpoons$	$\text{Ag}^+(aq)$	$+ 2\text{NH}_3(aq)$
Starting	0.010		0	0.98
Change	$-x$		$+x$	$+2x$
Equilibrium	$0.010 - x$		$x$	$0.98 + 2x$

**Step 2:** The formation constant is

$$K_f = \frac{[\text{Ag}(\text{NH}_3)_2^+]}{[\text{Ag}^+][\text{NH}_3]^2} = 1.7 \times 10^7$$

From this you can write the dissociation constant, which corresponds to the reaction as shown in the table.

$$\frac{[\text{Ag}^+][\text{NH}_3]^2}{[\text{Ag}(\text{NH}_3)_2^+]} = K_d = \frac{1}{K_f}$$

Substituting into this equation gives

$$\frac{x(0.98 + 2x)^2}{(0.010 - x)} = \frac{1}{1.7 \times 10^7}$$

**Step 3:** The right-hand side of the equation equals  $5.9 \times 10^{-8}$ . If you assume  $x$  to be small compared with  $0.010$ ,

$$\frac{x(0.98)^2}{0.010} \approx 5.9 \times 10^{-8}$$

and

$$x \approx 5.9 \times 10^{-8} \times 0.010 / (0.98)^2 = 6.1 \times 10^{-10}$$

The silver-ion concentration is  $6.1 \times 10^{-10}\text{ M}$  (over 10 million times smaller than its value in  $0.010\text{ M AgNO}_3$  that does not contain ammonia).

Richard Megna/Fundamental Photographs, NYC

**Formation of copper(II)-ammonia complex ion,  $\text{Cu}(\text{NH}_3)_4^{2+}$  (dark blue)** Ammonia is being added to copper sulfate solution (light blue), giving a precipitate of copper(II) hydroxide, which dissolves as the copper(II) ion complexes with more ammonia.

(continued)

**Example 17.9** (continued)

**Answer Check** Calculate the value of  $K_f$  from the equilibrium concentrations of species, using the value of  $x$  ( $6.1 \times 10^{-10}$ ) that you just obtained.

$$K_f = \frac{[\text{Ag}(\text{NH}_3)_2^+]}{[\text{Ag}^+][\text{NH}_3]^2} = \frac{(0.010 - x)}{x(0.98 + 2x)^2} = \frac{0.010}{6.1 \times 10^{-10}(0.98)^2} = 1.7 \times 10^7$$

**Exercise 17.9** What is the concentration of  $\text{Cu}^{2+}(aq)$  in a solution that was originally  $0.015 M \text{Cu}(\text{NO}_3)_2$  and  $0.100 M \text{NH}_3$ ? The  $\text{Cu}^{2+}$  ion forms the complex ion  $\text{Cu}(\text{NH}_3)_4^{2+}$ . Its formation constant is given in Table 17.2.

See Problems 17.64 and 17.65.

### Amphoteric Hydroxides

An **amphoteric hydroxide** is a metal hydroxide that reacts with both bases and acids. Zinc is an example of a metal that forms such a hydroxide. Zinc hydroxide,  $\text{Zn}(\text{OH})_2$ , is an insoluble hydroxide, as are most of the metal hydroxides except those of Groups 1A and 2A elements. Zinc hydroxide reacts with a strong acid, as you would expect of a base, and the metal hydroxide dissolves.

With a base, however,  $\text{Zn}(\text{OH})_2$  reacts to form the complex ion  $\text{Zn}(\text{OH})_4^{2-}$ .

In this way the hydroxide also dissolves in a strong base.

When a strong base is slowly added to a solution of  $\text{ZnCl}_2$ , a white precipitate of  $\text{Zn}(\text{OH})_2$  first forms.

But as more base is added, the white precipitate dissolves, forming the complex ion  $\text{Zn}(\text{OH})_4^{2-}$ . (See Figure 17.8.)

Other common amphoteric hydroxides are those of aluminum, chromium(III), lead(II), tin(II), and tin(IV). The amphoterism of  $\text{Al}(\text{OH})_3$  is commercially used to separate aluminum oxide from the aluminum ore bauxite. Bauxite contains hydrated  $\text{Al}_2\text{O}_3$  plus impurities, such as silica sand ( $\text{SiO}_2$ ) and iron oxide ( $\text{Fe}_2\text{O}_3$ ). The aluminum oxide dissolves in  $\text{NaOH}$  solution as the  $\text{Al}(\text{OH})_4^-$  ion. After the insoluble

**Figure 17.8** ▼

**Demonstration of the amphoteric behavior of zinc hydroxide**

The beaker on the left contains  $\text{ZnCl}_2$ ; the one on the right contains  $\text{NaOH}$ .

As some of the solution of  $\text{NaOH}$  is added to the solution of  $\text{ZnCl}_2$ , a white precipitate of  $\text{Zn}(\text{OH})_2$  forms.

After more  $\text{NaOH}$  is added, the precipitate dissolves by forming the hydroxo complex  $\text{Zn}(\text{OH})_4^{2-}$ .

impurities are filtered off, the solution of  $\text{Al(OH)}_4^-$  can be slightly acidified to precipitate pure  $\text{Al(OH)}_3$ .

## 17.6 Complex Ions and Solubility

Example 17.9 demonstrates that the formation of the complex ion  $\text{Ag(NH}_3)_2^+$  reduces the concentration of silver ion,  $\text{Ag}^+(aq)$ , in solution. The solution was initially  $0.010\text{ M}$   $\text{AgNO}_3$ , or  $0.010\text{ M}$   $\text{Ag}^+(aq)$ . When this solution is made  $1.00\text{ M}$  in  $\text{NH}_3$ , the  $\text{Ag}^+(aq)$  ion concentration decreases to  $6.1 \times 10^{-10}\text{ M}$ . You can see that the ion product for a slightly soluble silver salt could be decreased to below  $K_{sp}$ . Then the slightly soluble salt might not precipitate in a solution containing ammonia, whereas it otherwise would.

### Example 17.10 Predicting Whether a Precipitate Will Form in the Presence of the Complex Ion

#### Gaining Mastery Toolbox

##### Critical Concept 17.10

The formation of a complex ion can reduce the concentration of a metal ion to the extent that it affects whether a slightly soluble salt of this metal ion precipitates.

##### Solution Essentials:

- Solubility product constant,  $K_{sp}$
- Molar solubility
- Complex ion
- Formation constant,  $K_f$ , of a complex ion
- Reaction quotient
- Equilibrium constant,  $K_c$
- Molar concentration

- a. Will silver chloride precipitate from a solution that is  $0.010\text{ M}$   $\text{AgNO}_3$  and  $0.010\text{ M}$   $\text{NaCl}$ ? b. Will silver chloride precipitate from this solution if it is also  $1.00\text{ M}$   $\text{NH}_3$ ?

**Problem Strategy** Part a is a simple precipitation problem in which you compare  $Q_c$  with  $K_{sp}$ . See Example 17.6. Part b differs only in that you need to know the  $\text{Ag}^+$  concentration in equilibrium with a complex ion.

**Solution** a. To determine whether a precipitate should form, you calculate the ion product and compare it with  $K_{sp}$  for  $\text{AgCl}$  ( $1.8 \times 10^{-10}$ ).

$$\text{Ion product} = [\text{Ag}^+]_i[\text{Cl}^-]_i = (0.010)(0.010) = 1.0 \times 10^{-4}$$

This is greater than  $K_{sp} = 1.8 \times 10^{-10}$ , so **a precipitate should form**.

b. You first need to calculate the concentration of  $\text{Ag}^+(aq)$  in a solution containing  $1.00\text{ M}$   $\text{NH}_3$ . We did this in Example 17.9 and found that  $[\text{Ag}^+]$  equals  $6.1 \times 10^{-10}\text{ M}$ . Hence,

$$\text{Ion product} = [\text{Ag}^+]_i[\text{Cl}^-]_i = (6.1 \times 10^{-10})(0.010) = 6.1 \times 10^{-12}$$

Because the ion product is smaller than  $K_{sp} = 1.8 \times 10^{-10}$ , **no precipitate should form**.

**Answer Check** Check your arithmetic in calculating the ion product. Then note that when a precipitate forms, the ion product decreases as it approaches the solubility product. Therefore, the ion product,  $Q_c$ , should be larger than  $K_{sp}$  if a precipitate is to form.

**Exercise 17.10** Will silver iodide precipitate from a solution that is  $0.0045\text{ M}$   $\text{AgNO}_3$ ,  $0.15\text{ M}$   $\text{NaI}$ , and  $0.20\text{ M}$   $\text{KCN}$ ?

See Problems 17.65 and 17.66.

In Example 17.10, we determined whether a precipitate of  $\text{AgCl}$  is expected to form from a solution made up with given concentrations of  $\text{Ag}^+$ ,  $\text{Cl}^-$ , and  $\text{NH}_3$ . The problem involved the  $\text{Ag(NH}_3)_2^+$  complex in equilibrium. From it, we determined the concentration of free  $\text{Ag}^+(aq)$  and then calculated the ion product of  $\text{AgCl}$ .

Suppose you want to find the solubility of  $\text{AgCl}$  in a solution of aqueous ammonia of given concentration. This problem involves the solubility equilibrium for  $\text{AgCl}$ , in addition to the complex-ion equilibrium. As silver chloride dissolves to give ions, the  $\text{Ag}^+$  ion reacts with  $\text{NH}_3$  to give the complex ion  $\text{Ag(NH}_3)_2^+$ . The equilibria are

When  $\text{Ag}^+(aq)$  reacts to give the complex ion, more  $\text{AgCl}$  dissolves to partially replenish the  $\text{Ag}^+(aq)$  ion, according to Le Châtelier's principle. Therefore, silver chloride is more soluble in aqueous ammonia than in pure water. The next example shows how you can calculate this solubility.

### Example 17.11 Calculating the Solubility of a Slightly Soluble Ionic Compound in a Solution of the Complex Ion

#### Gaining Mastery Toolbox

##### Critical Concept 17.11

The formation of a complex ion reduces the concentration of a metal ion in solution and consequently increases the solubility of a slightly soluble salt of the metal ion.

##### Solution Essentials:

- Solubility product constant,  $K_{sp}$
- Molar solubility
- Complex ion
- Formation constant,  $K_f$ , of a complex ion
- Reaction quotient
- Equilibrium constant,  $K_c$
- Molar concentration

Calculate the molar solubility of AgCl in 1.0 M  $\text{NH}_3$ .

**Problem Strategy** If you add the solubility equilibrium and the complex-ion equilibrium (the two equations just before this example), you obtain the overall equilibrium for the dissolving of AgCl in  $\text{NH}_3$ . The equilibrium constant for this reaction equals the product of the equilibrium constants for solubility and complex-ion formation. (We will show that in the solution to this example; however, we discussed the general principle at the end of Section 14.2.) Once you have the equilibrium constant, you can solve the equilibrium problem.

**Solution** You obtain the overall equation for the process by adding the solubility and complex-ion equilibria.

The equilibrium constant for the overall equation is

$$K_c = \frac{[\text{Ag}(\text{NH}_3)_2^+][\text{Cl}^-]}{[\text{NH}_3]^2}$$

Because the overall equation is the sum of the solubility and complex-ion equilibria, the equilibrium constant  $K_c$  equals the product of the equilibrium constants for the solubility and complex-ion equilibria. You can easily verify this.

$$K_c = K_{sp}K_f = [\text{Ag}^+][\text{Cl}^-] \frac{[\text{Ag}(\text{NH}_3)_2^+]}{[\text{Ag}^+][\text{NH}_3]^2}$$

The value of  $K_c = K_{sp}K_f$  can be obtained from  $K_{sp}$  for AgCl in Table 17.1 and  $K_f$  for  $\text{Ag}(\text{NH}_3)_2^+$  in Table 17.2.

$$K_{sp}K_f = (1.8 \times 10^{-10})(1.7 \times 10^7) = 3.1 \times 10^{-3}$$

You now solve the equilibrium problem. The concentration table follows:

Concentration (M)	$\text{AgCl}(s) + 2\text{NH}_3(aq) \rightleftharpoons \text{Ag}(\text{NH}_3)_2^+(aq) + \text{Cl}^-(aq)$		
Starting	1.0	0	0
Change	-2x	+x	+x
Equilibrium	1.0 - 2x	x	x

Substituting into the equilibrium-constant equation

$$\frac{[\text{Ag}(\text{NH}_3)_2^+][\text{Cl}^-]}{[\text{NH}_3]^2} = K_{sp}K_f$$

gives

$$\frac{x^2}{(1.0 - 2x)^2} = 3.1 \times 10^{-3}$$

You solve this equation by taking the square root of both sides.

$$\frac{x}{1.0 - 2x} = 0.056$$

(continued)

**Example 17.11** (continued)

Rearranging yields

$$x = 0.056(1.0 - 2x) = 0.056 - 0.11x$$

Hence,

$$x = \frac{0.056}{1.11} = 0.050$$

Note that the molar solubility of AgCl equals the molar concentration of silver in the solution. Because of the stability of  $\text{Ag}(\text{NH}_3)_2^+$ , most of the silver in solution will be in the form of this complex ion. Therefore, because  $x$  equals the concentration of  $\text{Ag}(\text{NH}_3)_2^+$ , the molar solubility of AgCl equals **0.050 M**.

**Answer Check** Check that you have the correct overall equilibrium for the problem and that you have then done the arithmetic correctly for the equilibrium constant. Once you have the molar solubility of the compound,  $x$ , you can put  $x$  back into the equilibrium-constant expression and calculate the value of  $K_c$  as a final check.

**Exercise 17.11** What is the molar solubility of AgBr in 1.0 M  $\text{Na}_2\text{S}_2\text{O}_3$  (sodium thiosulfate)? Silver ion forms the complex ion  $\text{Ag}(\text{S}_2\text{O}_3)_2^{3-}$ . See Tables 17.1 and 17.2 for data.

See Problems 17.67 and 17.68.

## ► An Application of Solubility Equilibria

**Qualitative analysis** involves the determination of the identity of the substances present in a mixture. One scheme for the qualitative analysis of a solution of metal ions is based on the relative solubilities of the metal sulfides. This scheme is no longer widely used in practical analysis, having been largely replaced by modern instrumental methods. But it is still taught in general chemistry laboratory as a way of imparting some knowledge of inorganic chemistry while illustrating the concepts of solubility, buffers, and so forth. We will look at the main outline of the sulfide scheme.

### 17.7 Qualitative Analysis of Metal Ions

In the qualitative analysis scheme for metal ions, a cation is usually detected by the presence of a characteristic precipitate. For example, silver ion gives a white precipitate with chloride ion. But other ions also give a white precipitate with chloride ion. Therefore, you must first subject a mixture to a procedure that separates individual ions before applying a precipitation test to any particular ion.

Figure 17.9 shows a flowchart illustrating how the metal ions in an aqueous solution are first separated into five analytical groups. The Analytical Group 1 ions,  $\text{Ag}^+$ ,  $\text{Hg}_2^{2+}$ , and  $\text{Pb}^{2+}$ , are separated from a solution of other ions by adding dilute hydrochloric acid. The ions are precipitated as the chlorides  $\text{AgCl}$ ,  $\text{Hg}_2\text{Cl}_2$ , and  $\text{PbCl}_2$ , which are removed by filtering.

The other metal ions remain in the filtrate, the solution that passes through the filter. Many of these ions can be separated by precipitating them as metal sulfides with  $\text{H}_2\text{S}$ . This separation takes advantage of the fact that only the least soluble metal sulfides precipitate in acidic solution. After these are removed and the solution is made basic, other metal sulfides precipitate. ◀

Analytical Group 2 consists of metal ions precipitated as metal sulfides from a solution that is 0.3 M  $\text{H}_3\text{O}^+$  and is saturated with  $\text{H}_2\text{S}$ . ◀ The ions are  $\text{As}^{3+}$ ,  $\text{Bi}^{3+}$ ,  $\text{Cd}^{2+}$ ,  $\text{Cu}^{2+}$ ,  $\text{Hg}^{2+}$ ,  $\text{Pb}^{2+}$ ,  $\text{Sb}^{3+}$ , and  $\text{Sn}^{4+}$ . Lead(II) ion can appear in Analytical Group 2 as well as in Group 1, because  $\text{PbCl}_2$  is somewhat soluble and therefore  $\text{Pb}^{2+}$  may not be completely precipitated by HCl.

The solubility of the metal sulfides at different pH was discussed in Section 17.4.

Hydrogen sulfide is often prepared in the solution by adding thioacetamide,  $\text{CH}_3\text{CSNH}_2$ , and warming.

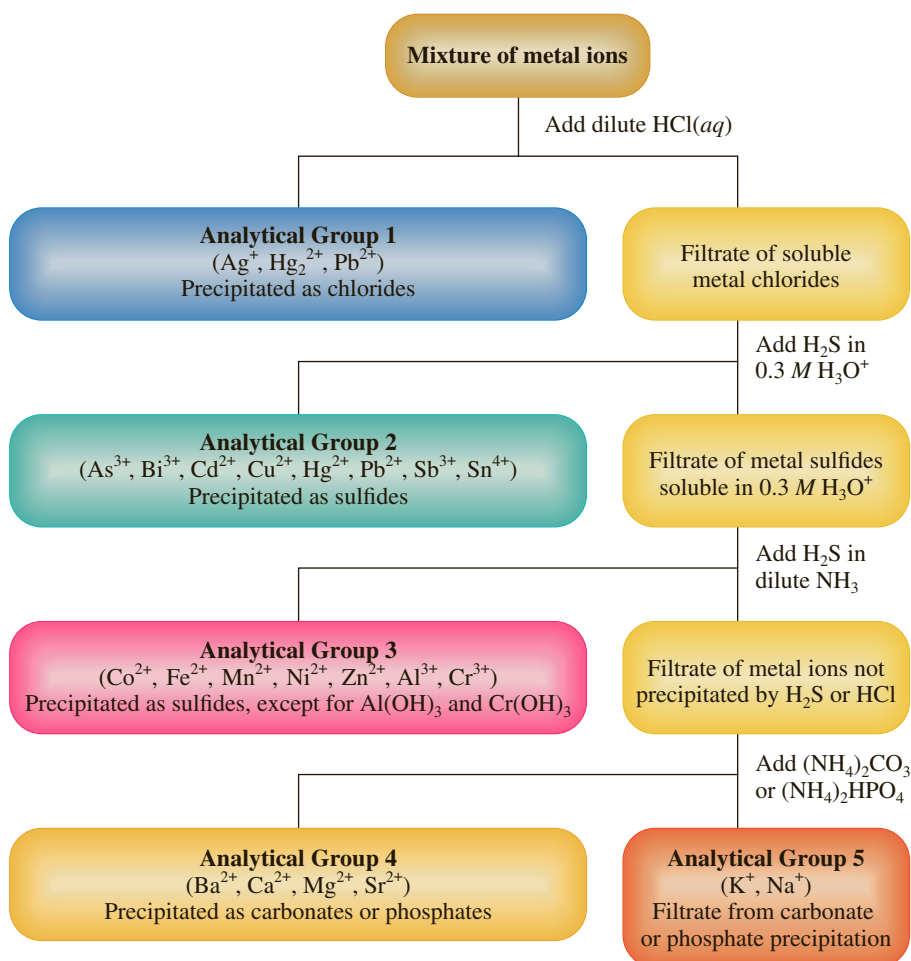

Figure 17.9 ◀

**Flowchart of the qualitative analysis scheme for the separation of metal ions** The first group of ions consists of those precipitated by HCl. The separation of the next two groups is based on the differences in solubilities of the metal sulfides. The fourth group consists of ions of the alkaline earth elements, which are precipitated as carbonates or phosphates. The final group of ions is in the filtrate after these precipitations.

Analytical Group 3 consists of the metal ions in the filtrate from Group 2 that are precipitated in weakly basic solution with H<sub>2</sub>S. The ions Co<sup>2+</sup>, Fe<sup>2+</sup>, Mn<sup>2+</sup>, Ni<sup>2+</sup>, and Zn<sup>2+</sup> are precipitated as the sulfides. The ions Al<sup>3+</sup> and Cr<sup>3+</sup> are precipitated as hydroxides.

The filtrate obtained after the Group 3 metal ions have precipitated contains the alkali metal ions and the alkaline earth ions. The Analytical Group 4 ions, Ba<sup>2+</sup>, Ca<sup>2+</sup>, Mg<sup>2+</sup>, and Sr<sup>2+</sup>, are precipitated as carbonates or phosphates by adding (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub> or (NH<sub>4</sub>)<sub>2</sub>HPO<sub>4</sub>. The filtrate from this separation contains the Analytical Group 5 ions, K<sup>+</sup> and Na<sup>+</sup>.

To illustrate the separation scheme, suppose you have a solution containing the metal cations Ag<sup>+</sup>, Cu<sup>2+</sup>, Zn<sup>2+</sup>, Ca<sup>2+</sup>, and Na<sup>+</sup>. When you add dilute HCl(aq) to this solution, Ag<sup>+</sup> precipitates as AgCl.

You filter off the precipitate of AgCl. The filtrate contains the remaining ions.

When you make the filtrate 0.3 M H<sub>3</sub>O<sup>+</sup> and then saturate it with H<sub>2</sub>S, the Cu<sup>2+</sup> ion precipitates as CuS.

Zinc(II) ion also forms a sulfide, but it is soluble in acidic solution. After removal of the precipitate of CuS, the solution is made weakly basic with NH<sub>3</sub>(aq). This increases the S<sup>2-</sup> concentration sufficiently to precipitate ZnS.

The filtrate from this separation contains  $\text{Ca}^{2+}$  and  $\text{Na}^+$ . Calcium ion can be precipitated as the phosphate or the carbonate. For example, by adding  $(\text{NH}_4)_2\text{CO}_3$ , you get the reaction

The filtrate from this solution contains  $\text{Na}^+$  ion. Now the five ions have been separated.

In the complete analysis, once the ions are separated into analytical groups, these are further separated into the individual ions. We can illustrate this with Analytical Group 1, which is precipitated as a mixture of the chlorides  $\text{AgCl}$ ,  $\text{Hg}_2\text{Cl}_2$ , and  $\text{PbCl}_2$ . Of these, only  $\text{PbCl}_2$  is significantly soluble in hot water. Thus, if the Analytical Group 1 precipitate is mixed with hot water, lead chloride dissolves and the silver and mercury(I) chlorides can be filtered off. Any lead(II) ion is in the filtrate and can be revealed by adding potassium chromate. Lead(II) ion gives a bright yellow precipitate of lead(II) chromate,  $\text{PbCrO}_4$ .

If there is precipitate remaining after the extraction with hot water, it consists of  $\text{AgCl}$ ,  $\text{Hg}_2\text{Cl}_2$ , or both. However, only silver ion forms a stable ammonia complex ion. Therefore, silver chloride dissolves in ammonia.

Mercury(I) chloride is simultaneously oxidized and reduced in ammonia solution, giving a precipitate of mercury(II) amido chloride,  $\text{HgNH}_2\text{Cl}$ , and mercury metal, which appears black because of its finely divided state.

The presence of silver ion in the filtrate is revealed by adding hydrochloric acid, which combines with the  $\text{NH}_3$ , releasing  $\text{Ag}^+(\text{aq})$  ion. The  $\text{Ag}^+(\text{aq})$  ion reacts with  $\text{Cl}^-(\text{aq})$  to give a white precipitate of  $\text{AgCl}$ .

The other analytical groups are separated in similar fashion. Once a given ion has been separated, its presence is usually confirmed by a particular reactant—perhaps one that gives a distinctive precipitate.

### Summary of Facts and Concepts

The equilibrium constant for the equilibrium between a slightly soluble ionic solid and its ions in solution is called the *solubility product constant*,  $K_{sp}$ . Its value can be determined from the solubility of the solid. Conversely, when the solubility product constant is known, the solubility of the solid can be calculated. The solubility is decreased by the addition of a soluble salt that supplies a common ion. Qualitatively, this can be seen to follow from Le Châtelier's principle. Quantitatively, the *common-ion effect* on solubility can be evaluated from the solubility product constant.

Rather than look at the solubility process as the dissolving of a solid in a solution, you can look at it as the

*precipitation* of the solid from the solution. You can decide whether precipitation will occur by computing the *ion product*. Precipitation occurs when the ion product is greater than  $K_{sp}$ .

*Solubility is affected by the pH* if the compound supplies an anion conjugate to a weak acid. As the pH decreases ( $\text{H}_3\text{O}^+$  ion concentration increases), the anion concentration decreases because the anion forms the weak acid. Therefore, the ion product decreases and the solubility increases.

The concentration of a metal ion in solution is decreased by *complex-ion formation*. The equilibrium constant for the formation of the complex ion from the aqueous metal ion

and the ligands is called the *formation constant* (or *stability constant*),  $K_f$ . Because complex-ion formation reduces the concentration of aqueous metal ion, an ionic compound of the metal is more soluble in a solution of the ligand.

The sulfide scheme of *qualitative analysis* separates the metal ions in a mixture by using precipitation reactions. Variation of solubility with pH and with complex-ion formation is used to aid in the separation.

## Learning Objectives

## Important Terms

### 17.1 The Solubility Product Constant

- Define the *solubility product constant*,  $K_{sp}$ .
- Write solubility product expressions. **Example 17.1**
- Define *molar solubility*.
- Calculate  $K_{sp}$  from the solubility (simple example). **Example 17.2**
- Calculate  $K_{sp}$  from the solubility (more complicated example). **Example 17.3**
- Calculate the solubility from  $K_{sp}$ . **Example 17.4**

solubility product constant ( $K_{sp}$ )

### 17.2 Solubility and the Common-Ion Effect

- Explain how the solubility of a salt is affected by another salt that has the same cation or anion (*common ion*).
- Calculate the solubility of a slightly soluble salt in a solution of a common ion. **Example 17.5**

### 17.3 Precipitation Calculations

- Define *ion product*.
- State the criterion for precipitation.
- Predict whether precipitation will occur, given ion concentrations. **Example 17.6**
- Predict whether precipitation will occur, given solution volumes and concentrations. **Example 17.7**
- Define *fractional precipitation*.
- Explain how two ions can be separated using fractional precipitation.

ion product  
fractional precipitation

### 17.4 Effect of pH on Solubility

- Explain the qualitative effect of pH on solubility of a slightly soluble salt.
- Determine the qualitative effect of pH on solubility. **Example 17.8**
- Explain the basis for the sulfide scheme to separate a mixture of metal ions.

### 17.5 Complex-Ion Formation

- Define *complex ion* and *ligand*.
- Define *formation constant* or *stability constant*,  $K_f$ , and *dissociation constant*,  $K_d$ .
- Calculate the concentration of a metal ion in equilibrium with a complex ion. **Example 17.9**
- Define *amphoteric hydroxide*.

complex ion  
ligand  
formation (stability) constant ( $K_f$ )  
dissociation constant (of a complex ion) ( $K_d$ )  
amphoteric hydroxide

### 17.6 Complex Ions and Solubility

- Predict whether a precipitate will form in the presence of the complex ion. **Example 17.10**
- Calculate the solubility of a slightly soluble ionic compound in a solution of the complex ion. **Example 17.11**

### 17.7 Qualitative Analysis of Metal Ions

- Define *qualitative analysis*.
- Describe the main outline of the sulfide scheme for qualitative analysis.

qualitative analysis

## Questions and Problems

### Self-Assessment and Review Questions

**Key:** These questions test your understanding of the ideas you worked with in the chapter. These problems vary in difficulty and often can be used for the basis of discussion.

**17.1** Suppose the molar solubility of nickel hydroxide,  $\text{Ni}(\text{OH})_2$ , is  $x$   $M$ . Show that  $K_{sp}$  for nickel hydroxide equals  $4x^3$ .

**17.2** Explain why calcium sulfate is less soluble in sodium sulfate solution than in pure water.

**17.3** What must be the concentration of silver ion in a solution that is in equilibrium with solid silver chloride and that is  $0.10$   $M$  in  $\text{Cl}^-$ ?

**17.4** Discuss briefly how you could predict whether a precipitate will form when solutions of lead nitrate and potassium iodide are mixed. What information do you need to have?

**17.5** Explain why barium fluoride dissolves in dilute hydrochloric acid but is insoluble in water.

**17.6** Explain how metal ions such as  $\text{Pb}^{2+}$  and  $\text{Zn}^{2+}$  are separated by precipitation with hydrogen sulfide.

**17.7** Lead chloride at first precipitates when sodium chloride is added to a solution of lead nitrate. Later, when the solution is made more concentrated in chloride ion, the precipitate dissolves. Explain what is happening. What equilibria are involved? Note that lead ion forms the complex ion  $\text{PbCl}_4^{2-}$ .

**17.8** A precipitate forms when a small amount of sodium hydroxide is added to a solution of aluminum sulfate. This precipitate dissolves when more sodium hydroxide is added. Explain what is happening.

**17.9** Describe how you would separate the metal ions in a solution containing silver ion, copper(II) ion, and nickel(II) ion, using the sulfide scheme of qualitative analysis.

**17.10** A solution containing calcium ion and magnesium ion is buffered with ammonia–ammonium chloride. When carbonate ion is added to the solution, calcium carbonate precipitates but magnesium carbonate does not. Explain.

**17.11** The solubility of the hypothetical salt  $\text{A}_3\text{B}_2$  is  $6.1 \times 10^{-9}$  mol/L at a certain temperature. What is  $K_{sp}$  for the salt?  $\text{A}_3\text{B}_2$  dissolves according to the equation

- a  $3.7 \times 10^{-17}$
- b  $9.1 \times 10^{-25}$
- c  $9.1 \times 10^{-40}$
- d  $3.7 \times 10^{-32}$
- e  $1.4 \times 10^{-33}$

**17.12** Write the solubility product expression for the salt  $\text{Ag}_3\text{PO}_4$ .

- a  $K_{sp} = 3[\text{Ag}^+] \times [\text{PO}_4^{3-}]$
- b  $K_{sp} = [\text{Ag}^+][\text{PO}_4^{3-}]^3$
- c  $K_{sp} = [\text{Ag}^+]^3[\text{P}^{3-}][\text{O}^{2-}]^4$
- d  $K_{sp} = [\text{Ag}^{3+}][\text{PO}_4^{3-}]^3$
- e  $K_{sp} = [\text{Ag}^+]^3[\text{PO}_4^{3-}]$

**17.13** What is the molar solubility of calcium oxalate,  $\text{CaC}_2\text{O}_4$ , in a  $0.203$   $M$  calcium chloride solution? The solubility product constant for calcium oxalate is  $2.3 \times 10^{-9}$ .

- a  $4.8 \times 10^{-5}$   $M$
- b  $6.6 \times 10^{-6}$   $M$
- c  $8.0 \times 10^{-6}$   $M$
- d  $1.1 \times 10^{-8}$   $M$
- e  $1.2 \times 10^{-5}$   $M$

**17.14** Suppose the  $K_a$  values for the hypothetical acids  $\text{HX}$ ,  $\text{HY}$ , and  $\text{HZ}$  are  $9.5 \times 10^{-5}$ ,  $7.6 \times 10^{-4}$ , and  $1.2 \times 10^{-2}$ , respectively. Assuming that “A” is a cation that produces a slightly soluble salt with all three acids, which of the following salts would have its solubility most affected (compared with its solubility in pure water) when it is dissolved in a  $0.10$   $M$  solution of  $\text{HCl}$ ?

- a AX
- b AY
- c AZ
- d The solubility of all the salts would be affected by the same amount.
- e There is not enough information given in the problem to determine the answer.

### Concept Explorations

**Key:** Concept explorations are comprehensive problems that provide a framework that will enable you to explore and learn many of the critical concepts and ideas in each chapter. If you master the concepts associated with these explorations, you will have a better understanding of many important chemistry ideas and will be more successful in solving all types of chemistry problems. These problems are well suited for group work and for use as in-class activities.

#### 17.15 Solubility and Solubility Product

You put  $0.10$ -mol samples of  $\text{KNO}_3$ ,  $(\text{NH}_4)_2\text{S}$ ,  $\text{K}_2\text{S}$ ,  $\text{MnS}$ ,  $\text{AgCl}$ , and  $\text{BaSO}_4$  into separate flasks and add  $1.0$  L of water to each one. Then you stir the solutions for 5 minutes

at room temperature. Assume that you have  $1.0$  L of solution in each case.

- a Are there any beakers where you would observe solid still present? How do you know?
- b Can you calculate the potassium ion concentration,  $\text{K}^+$ , for the solutions of  $\text{KNO}_3$  and  $\text{K}_2\text{S}$ ? If so, do the calculations, and then compare these  $\text{K}^+$  concentrations.
- c For the solutions of  $(\text{NH}_4)_2\text{S}$ ,  $\text{K}_2\text{S}$ , and  $\text{MnS}$ , how do the concentrations of sulfide ion,  $\text{S}^{2-}$ , compare? (You don't need to calculate an answer at this point; just provide a rough comparison.) Be sure to justify your answer.
- d Are there any cases where you need more information to calculate the sulfide-ion concentration for the

solutions of  $(\text{NH}_4)_2\text{S}$ ,  $\text{K}_2\text{S}$ , and  $\text{MnS}$  from part c? If so, what additional information do you need?

- e Consider all of the solutions listed at the beginning of this problem. For which ones do you need more information than is given in the question to determine the concentrations of the ions present? Where can you find this information?
- f How is the solubility of an ionic compound related to the concentrations of the ions of the dissolved compound in solution?

### 17.16 Solubility Equilibria

Consider three hypothetical ionic solids:  $\text{AX}$ ,  $\text{AX}_2$ , and  $\text{AX}_3$  (each X forms  $\text{X}^-$ ). Each of these solids has the same  $K_{sp}$  value,  $5.5 \times 10^{-7}$ . You place 0.25 mol of each compound in a separate container and add enough water to bring the volume to 1.0 L in each case.

- a Write the chemical equation for each of the solids dissolving in water.
- b Would you expect the concentration of each solution to be 0.25 M in the compound? Explain, in some detail, why or why not.
- c Would you expect the concentrations of the A cations ( $\text{A}^+$ ,  $\text{A}^{2+}$ , and  $\text{A}^{3+}$ ) in the three solutions to be the same? Does just knowing the stoichiometry of each reaction help you determine the answer, or do you need something else? Explain your answer in detail, but without doing any arithmetic calculations.
- d Of the three solids, which one would you expect to have the greatest molar solubility? Explain in detail, but without doing any arithmetic calculations.
- e Calculate the molar solubility of each compound.

## Conceptual Problems

**Key:** These problems are designed to check your understanding of the concepts associated with some of the main topics presented in each chapter. A strong conceptual understanding of chemistry is the foundation for both applying chemical knowledge and solving chemical problems. These problems vary in level of difficulty and often can be used as a basis for group discussion.

17.17 Which compound in each of the following pairs of compounds is the more soluble one?

- a silver chloride or silver iodide
- b magnesium hydroxide or copper(II) hydroxide

17.18 You are given two mineral samples: halite, which is  $\text{NaCl}$ , and fluorite, which is  $\text{CaF}_2$ . Describe a simple test you could use to discover which mineral is fluorite.

17.19 You are given a saturated solution of lead(II) chloride. Which one of the following solutions would be most effective in yielding a precipitate when added to the lead(II) chloride solution?

- a 0.1 M  $\text{NaCl}(aq)$
- b saturated  $\text{PbS}(aq)$
- c 0.1 M  $\text{NaSO}_4(aq)$

17.20 Which of the following pictures best represents a solution made by adding 10 g of silver chloride,  $\text{AgCl}$ , to a liter of water? In these pictures, the gray spheres represent  $\text{Ag}^+$  ions and the green spheres represent chloride ions. For clarity, water molecules are not shown.

17.21 Which of the following pictures best represents an unsaturated solution of sodium chloride,  $\text{NaCl}$ ? In these pictures, the dark gray spheres represent  $\text{Na}^+$  ions and the green spheres represent chloride ions. For clarity, water molecules are not shown.

17.22 When ammonia is first added to a solution of copper(II) nitrate, a pale blue precipitate of copper(II) hydroxide forms. As more ammonia is added, however, this precipitate dissolves. Describe what is happening.

17.23 You are given a solution of the ions  $\text{Mg}^{2+}$ ,  $\text{Ca}^{2+}$ , and  $\text{Ba}^{2+}$ . Devise a scheme to separate these ions using sodium sulfate. Note that magnesium sulfate is soluble.

17.24 You add dilute hydrochloric acid to a solution containing a metal ion. No precipitate forms. After the acidity is adjusted to 0.3 M hydronium ion, you bubble hydrogen sulfide into the solution. Again no precipitate forms. Is it possible that the original solution contained silver ion? Could it have contained copper(II) ion?

## Practice Problems

**Key:** These problems are for practice in applying problem-solving skills. They are divided by topic, and some are keyed to exercises (see the ends of the exercises). The problems are

arranged in matching pairs; the odd-numbered problem of each pair is listed first, and its answer is given in the back of the book.

Note: For values of  $K_{sp}$  and  $K_f$  that are not given in the following problems, see Tables 17.1 and 17.2.

### Solubility and $K_{sp}$

**17.25** Use the solubility rules (Table 4.1) to decide which of the following compounds are expected to be soluble and which insoluble.

**a**  $\text{Mg}(\text{C}_2\text{H}_3\text{O}_2)_2$  **b**  $\text{NiS}$  **c**  $\text{Cr}(\text{NO}_3)_2$  **d**  $\text{Ca}_3(\text{PO}_4)_2$

**17.26** Use the solubility rules (Table 4.1) to decide which of the following compounds are expected to be soluble and which insoluble.

**a**  $\text{AgBr}$  **b**  $\text{Ca}(\text{NO}_3)_2$  **c**  $\text{MgI}_2$  **d**  $\text{PbSO}_4$

**17.27** Write solubility product expressions for the following compounds.

**a**  $\text{Mg}(\text{OH})_2$  **b**  $\text{SrCO}_3$   
**c**  $\text{Ca}_3(\text{AsO}_4)_2$  **d**  $\text{Fe}(\text{OH})_3$

**17.28** Write solubility product expressions for the following compounds.

**a**  $\text{Ba}_3(\text{PO}_4)_2$  **b**  $\text{FePO}_4$  **c**  $\text{Ag}_2\text{S}$  **d**  $\text{PbI}_2$

**17.29** The solubility of silver iodate,  $\text{AgIO}_3$ , in water is 0.051 g/L. Calculate  $K_{sp}$ .

**17.30** The solubility of magnesium oxalate,  $\text{MgC}_2\text{O}_4$ , in water is 0.0093 mol/L. Calculate  $K_{sp}$ .

**17.31** The solubility of cobalt(II) iodate in water is 1.2 g/100 mL. Calculate the solubility product constant for cobalt(II) iodate,  $\text{Co}(\text{IO}_3)_2$ .

**17.32** The solubility of nickel(II) carbonate,  $\text{NiCO}_3$ , in water is 0.0448 g/L. Calculate  $K_{sp}$ .

**17.33** The pH of a saturated solution of copper(II) hydroxide,  $\text{Cu}(\text{OH})_2$  was found to be 7.91. From this, find  $K_{sp}$  for copper(II) hydroxide.

**17.34** A solution saturated in calcium hydroxide (limewater) has a pH of 12.35. What is  $K_{sp}$  for calcium hydroxide?

**17.35** Strontianite (strontium carbonate) is an important mineral of strontium. Calculate the solubility of strontium carbonate,  $\text{SrCO}_3$ , from the solubility product constant.

**17.36** Magnesite (magnesium carbonate,  $\text{MgCO}_3$ ) is a common magnesium mineral. From the solubility product constant, find the solubility of magnesium carbonate in grams per liter of water.

**17.37** What is the solubility of  $\text{PbF}_2$  in water? The  $K_{sp}$  for  $\text{PbF}_2$  is  $2.7 \times 10^{-8}$ .

**17.38** What is the solubility of strontium iodate,  $\text{Sr}(\text{IO}_3)_2$ , in water? The  $K_{sp}$  for  $\text{Sr}(\text{IO}_3)_2$  is  $1.14 \times 10^{-7}$ .

### Common-Ion Effect

**17.39** What is the solubility (in grams per liter) of strontium sulfate,  $\text{SrSO}_4$ , in 0.36 M sodium sulfate,  $\text{Na}_2\text{SO}_4$ ?

**17.40** What is the solubility (in grams per liter) of lead(II) chromate,  $\text{PbCrO}_4$ , in 0.13 M potassium chromate,  $\text{K}_2\text{CrO}_4$ ?

**17.41** The solubility of magnesium fluoride,  $\text{MgF}_2$ , in water is 0.015 g/L. What is the solubility (in grams per liter) of magnesium fluoride in 0.17 M sodium fluoride,  $\text{NaF}$ ?

**17.42** The solubility of silver sulfate,  $\text{Ag}_2\text{SO}_4$ , in water has been determined to be 8.0 g/L. What is the solubility in 0.45 M sodium sulfate,  $\text{Na}_2\text{SO}_4$ ?

**17.43** What is the solubility (in grams per liter) of magnesium oxalate,  $\text{MgC}_2\text{O}_4$ , in 0.020 M sodium oxalate,  $\text{Na}_2\text{C}_2\text{O}_4$ ? Solve the equation exactly.

**17.44** Calculate the molar solubility of strontium sulfate,  $\text{SrSO}_4$ , in 0.0012 M sodium sulfate,  $\text{Na}_2\text{SO}_4$ . Solve the equation exactly.

### Precipitation

**17.45** From each of the following ion concentrations in a solution, predict whether a precipitate will form in the solution.

**a**  $[\text{Ba}^{2+}] = 0.040 \text{ M}$ ,  $[\text{F}^-] = 0.0025 \text{ M}$   
**b**  $[\text{Pb}^{2+}] = 0.060 \text{ M}$ ,  $[\text{Cl}^-] = 0.034 \text{ M}$

**17.46** From each of the following ion concentrations in a solution, predict whether a precipitate will form in the solution.

**a**  $[\text{Sr}^{2+}] = 0.012 \text{ M}$ ,  $[\text{CO}_3^{2-}] = 0.0015 \text{ M}$   
**b**  $[\text{Pb}^{2+}] = 0.0048 \text{ M}$ ,  $[\text{Cl}^-] = 0.082 \text{ M}$

**17.47** Lead(II) chromate,  $\text{PbCrO}_4$ , was used as a yellow paint pigment (“chrome yellow”). When a solution is prepared that is  $5.0 \times 10^{-4} \text{ M}$  in lead ion,  $\text{Pb}^{2+}$ , and  $5.0 \times 10^{-5} \text{ M}$  in chromate ion,  $\text{CrO}_4^{2-}$ , would you expect some of the lead(II) chromate to precipitate?

**17.48** Lead sulfate,  $\text{PbSO}_4$ , was used as a white paint pigment. When a solution is prepared that is  $5.0 \times 10^{-3} \text{ M}$  in lead ion,  $\text{Pb}^{2+}$ , and  $1.0 \times 10^{-4} \text{ M}$  in sulfate ion,  $\text{SO}_4^{2-}$ , would you expect some of the lead sulfate to precipitate?

**17.49** The following solutions are mixed: 1.0 L of 0.00010 M NaOH and 1.0 L of 0.0014 M  $\text{MgSO}_4$ . Is a precipitate expected? Explain.

**17.50** A 45-mL sample of 0.015 M calcium chloride,  $\text{CaCl}_2$ , is added to 55 mL of 0.010 M sodium sulfate,  $\text{Na}_2\text{SO}_4$ . Is a precipitate expected? Explain.

**17.51** A 45.0-mL sample of 0.0015 M  $\text{BaCl}_2$  was added to a beaker containing 75.0 mL of 0.0025 M KF. Will a precipitate form?

**17.52** A 65.0-mL sample of 0.010 M  $\text{Pb}(\text{NO}_3)_2$  was added to a beaker containing 40.0 mL of 0.035 M KCl. Will a precipitate form?

**17.53** How many moles of calcium chloride,  $\text{CaCl}_2$ , can be added to 1.5 L of 0.020 M potassium sulfate,  $\text{K}_2\text{SO}_4$ , before a precipitate is expected? Assume that the volume of the solution is not changed significantly by the addition of calcium chloride.

**17.54** Magnesium sulfate,  $\text{MgSO}_4$ , is added to 456 mL of 0.040 M sodium hydroxide, NaOH, until a precipitate just forms. How many grams of magnesium sulfate were added? Assume that the volume of the solution is not changed significantly by the addition of magnesium sulfate.

**17.55** What is the  $\text{I}^-$  concentration just as AgCl begins to precipitate when 1.0 M  $\text{AgNO}_3$  is slowly added to a solution containing 0.015 M  $\text{Cl}^-$  and 0.015 M  $\text{I}^-$ ?

**17.56** What is the  $\text{Cl}^-$  concentration just as  $\text{Ag}_2\text{CrO}_4$  begins to precipitate when  $0.90\text{ M AgNO}_3$  is slowly added to a solution containing  $0.015\text{ M Cl}^-$  and  $0.015\text{ M CrO}_4^{2-}$ ?

### Effect of pH on Solubility

**17.57** Write the net ionic equation in which the slightly soluble salt barium fluoride,  $\text{BaF}_2$ , dissolves in dilute hydrochloric acid.

**17.58** Write the net ionic equation in which the slightly soluble salt magnesium carbonate,  $\text{MgCO}_3$ , dissolves in dilute hydrochloric acid.

**17.59** Which salt would you expect to dissolve more readily in acidic solution, barium sulfate or barium fluoride? Explain.

**17.60** Which salt would you expect to dissolve more readily in acidic solution, strontium phosphate,  $\text{Sr}_3(\text{PO}_4)_2$ , or strontium sulfate,  $\text{SrSO}_4$ ? Explain.

### Complex Ions

**17.61** Write the chemical equation for the formation of the  $\text{Cu}(\text{CN})_2^-$  ion. Write the  $K_f$  expression.

**17.62** Write the chemical equation for the formation of the  $\text{Fe}(\text{CN})_6^{3-}$  ion. Write the  $K_f$  expression.

**17.63** Sufficient sodium cyanide,  $\text{NaCN}$ , was added to  $0.015\text{ M}$  silver nitrate,  $\text{AgNO}_3$ , to give a solution that was initially  $0.108\text{ M}$  in cyanide ion,  $\text{CN}^-$ . What is the concentration of silver ion,  $\text{Ag}^+$ , in this solution after  $\text{Ag}(\text{CN})_2^-$  forms? The formation constant  $K_f$  for the complex ion  $\text{Ag}(\text{CN})_2^-$  is  $5.6 \times 10^{18}$ .

**17.64** The formation constant  $K_f$  for the complex ion  $\text{Zn}(\text{OH})_4^{2-}$  is  $2.8 \times 10^{15}$ . What is the concentration of zinc ion,  $\text{Zn}^{2+}$ , in a solution that is initially  $0.20\text{ M}$  in  $\text{Zn}(\text{OH})_4^{2-}$ ?

**17.65** Predict whether cadmium oxalate,  $\text{CdC}_2\text{O}_4$ , will precipitate from a solution that is  $0.0020\text{ M Cd}(\text{NO}_3)_2$ ,  $0.010\text{ M Na}_2\text{C}_2\text{O}_4$ , and  $0.10\text{ M NH}_3$ . Note that cadmium ion forms the  $\text{Cd}(\text{NH}_3)_4^{2+}$  complex ion.

**17.66** Predict whether nickel(II) hydroxide,  $\text{Ni}(\text{OH})_2$ , will precipitate from a solution that is  $0.0020\text{ M NiSO}_4$ ,  $0.010\text{ M NaOH}$ , and  $0.10\text{ M NH}_3$ . Note that nickel(II) ion forms the  $\text{Ni}(\text{NH}_3)_6^{2+}$  complex ion.

**17.67** What is the molar solubility of  $\text{CdC}_2\text{O}_4$  in  $0.10\text{ M NH}_3$ ?

**17.68** What is the molar solubility of  $\text{ZnS}$  in  $0.10\text{ M NH}_3$ ?

### Qualitative Analysis

**17.69** Describe how you could separate the following mixture of metal ions:  $\text{Cd}^{2+}$ ,  $\text{Pb}^{2+}$ , and  $\text{Sr}^{2+}$ .

**17.70** Describe how you could separate the following mixture of metal ions:  $\text{Na}^+$ ,  $\text{Hg}^{2+}$ , and  $\text{Ca}^{2+}$ .

**17.71** A student dissolved a compound in water and added hydrochloric acid. No precipitate formed. Next she bubbled  $\text{H}_2\text{S}$  into this solution, but again no precipitate formed. However, when she made the solution basic with ammonia and bubbled in  $\text{H}_2\text{S}$ , a precipitate formed. Which of the following are possible as the cation in the compound?

- a**  $\text{Ag}^+$    **b**  $\text{Ca}^{2+}$    **c**  $\text{Mn}^{2+}$    **d**  $\text{Cd}^{2+}$

**17.72** A student was asked to identify a compound. In an effort to do so, he first dissolved the compound in water. He found that no precipitate formed when hydrochloric acid was added, but when  $\text{H}_2\text{S}$  was bubbled into this acidic solution, a precipitate formed. Which one of the following could be the precipitate?

- a**  $\text{PbS}$    **b**  $\text{MnS}$    **c**  $\text{CdS}$    **d**  $\text{Ag}_2\text{S}$

## General Problems

**Key:** These problems provide more practice but are not divided by topic or keyed to exercises. Each section ends with essay questions, each of which is color coded to refer to the *A Chemist Looks at Environment* (green) chapter essay on which it is based. Odd-numbered problems and the even-numbered problems that follow are similar; answers to all odd-numbered problems except the essay questions are given in the back of the book.

**17.73** Lead(II) sulfate is often used as a test for lead(II) ion in qualitative analysis. Using the solubility product constant, calculate the molar solubility of lead(II) sulfate in water.

**17.74** Mercury(II) ion is often precipitated as mercury(II) sulfide in qualitative analysis. Using the solubility product constant, calculate the molar solubility of mercury(II) sulfide in water, assuming that no other reactions occur.

**17.75** Mercury(I) chloride,  $\text{Hg}_2\text{Cl}_2$ , is an unusual salt in that it dissolves to form  $\text{Hg}_2^{2+}$  and  $2\text{Cl}^-$ . Use the solubility product constant to calculate the following: **a** the molar solubility of  $\text{Hg}_2\text{Cl}_2$ ; **b** the solubility of  $\text{Hg}_2\text{Cl}_2$  in grams per liter.

**17.76** Magnesium ammonium phosphate is an unusual salt in that it dissolves to form  $\text{Mg}^{2+}$ ,  $\text{NH}_4^+$ , and  $\text{PO}_4^{3-}$  ions.  $K_{sp}$  for magnesium ammonium phosphate equals  $2.5 \times 10^{-13}$ . Calculate: **a** its molar solubility; **b** its solubility in grams per liter.

**17.77** For cerium(III) hydroxide,  $\text{Ce}(\text{OH})_3$ ,  $K_{sp}$  equals  $2.0 \times 10^{-20}$ . Calculate: **a** its molar solubility (recall that taking the square root twice gives the fourth root); **b** the pOH of the saturated solution.

**17.78** Copper(II) ferrocyanide,  $\text{Cu}_2\text{Fe}(\text{CN})_6$ , dissolves to give  $\text{Cu}^{2+}$  and  $[\text{Fe}(\text{CN})_6]^{4-}$  ions;  $K_{sp}$  for  $\text{Cu}_2\text{Fe}(\text{CN})_6$  equals  $1.3 \times 10^{-16}$ . Calculate: **a** the molar solubility, and **b** the solubility in grams per liter of copper(II) ferrocyanide.

**17.79** What is the solubility of magnesium hydroxide in a solution buffered at pH 9.20?

**17.80** What is the solubility of silver oxide,  $\text{Ag}_2\text{O}$ , in a solution buffered at pH 10.78? The equilibrium is  $\text{Ag}_2\text{O}(\text{s}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons 2\text{Ag}^+(\text{aq}) + 2\text{OH}^-(\text{aq})$ ;  $K_c = 2.0 \times 10^{-8}$ .

**17.81** What is the molar solubility of  $\text{Mg}(\text{OH})_2$  in a solution containing  $1.0 \times 10^{-1}\text{ M NaOH}$ ?

**17.82** What is the molar solubility of  $\text{Al}(\text{OH})_3$  in a solution containing  $1.5 \times 10^{-3} \text{ M NaOH}$ ?

**17.83** What must be the concentration of sulfate ion in order to precipitate calcium sulfate,  $\text{CaSO}_4$ , from a solution that is  $0.0030 \text{ M Ca}^{2+}$ ?

**17.84** What must be the concentration of chromate ion in order to precipitate strontium chromate,  $\text{SrCrO}_4$ , from a solution that is  $0.0034 \text{ M Sr}^{2+}$ ?

**17.85** A 3.20-L solution of  $1.25 \times 10^{-3} \text{ M Pb}(\text{NO}_3)_2$  is mixed with a 0.80-L solution of  $5.0 \times 10^{-1} \text{ M NaCl}$ . Calculate  $Q_c$  for the dissolution of  $\text{PbCl}_2$ . No precipitate has formed. Is the solution supersaturated, saturated, or unsaturated?

**17.86** A 0.150-L solution of  $2.4 \times 10^{-5} \text{ M MgCl}_2$  is mixed with 0.050 L of  $4.0 \times 10^{-3} \text{ M NaOH}$ . Calculate  $Q_c$  for the dissolution of  $\text{Mg}(\text{OH})_2$ . No precipitate has formed. Is the solution supersaturated, saturated, or unsaturated?

**17.87** How many grams of sodium chloride can be added to 785 mL of  $0.0015 \text{ M}$  silver nitrate before a precipitate forms?

**17.88** How many grams of sodium sulfate can be added to 446 mL of  $0.0032 \text{ M}$  barium chloride before a precipitate forms?

**17.89** Solid  $\text{KSCN}$  was added to a  $2.00 \text{ M Fe}^{3+}$  solution so that it was also initially  $2.00 \text{ M SCN}^-$ . These ions then reacted to give the complex ion  $\text{Fe}(\text{SCN})^{2+}$ , whose formation constant is  $9.0 \times 10^2$ . What is the concentration of  $\text{Fe}^{3+}(\text{aq})$  at equilibrium? Be sure to check any simplifying assumption you make.

**17.90** Solid  $\text{KSCN}$  was added to a  $2.00 \text{ M Co}^{2+}$  solution so that it was also initially  $2.00 \text{ M SCN}^-$ . These ions then reacted to give the complex ion  $\text{Co}(\text{SCN})^+$ , whose formation constant is  $1.0 \times 10^2$ . What is the concentration of  $\text{Co}^{2+}(\text{aq})$  at equilibrium? Be sure to check any simplifying assumption you make.

**17.91** Calculate the molar solubility of silver bromide,  $\text{AgBr}$ , in  $5.0 \text{ M NH}_3$ .

**17.92** Calculate the molar solubility of silver iodide,  $\text{AgI}$ , in  $2.2 \text{ M NH}_3$ .

**17.93** The solubility of zinc oxalate,  $\text{ZnC}_2\text{O}_4$ , in  $0.0150 \text{ M}$  ammonia is  $3.6 \times 10^{-4} \text{ mol/L}$ . What is the oxalate-ion concentration in the saturated solution? If the solubility product constant for zinc oxalate is  $1.5 \times 10^{-9}$ , what must be the zinc-ion concentration in the solution? Now calculate the formation constant for the complex ion  $\text{Zn}(\text{NH}_3)_4^{2+}$ .

**17.94** The solubility of cadmium oxalate,  $\text{CdC}_2\text{O}_4$ , in  $0.150 \text{ M}$  ammonia is  $6.1 \times 10^{-3} \text{ mol/L}$ . What is the oxalate-ion concentration in the saturated solution? If the solubility product constant for cadmium oxalate is  $1.5 \times 10^{-8}$ , what must be the cadmium-ion concentration in the solution? Now calculate the formation constant for the complex ion  $\text{Cd}(\text{NH}_3)_4^{2+}$ .

**17.95** Ammonia,  $\text{NH}_3$ , is a base that ionizes to give  $\text{NH}_4^+$  and  $\text{OH}^-$  ( $K_b = 1.8 \times 10^{-5}$ ). You add magnesium sulfate to an ammonia solution. Calculate the concentration of  $\text{Mg}^{2+}$  ion when magnesium hydroxide,  $\text{Mg}(\text{OH})_2$ , just begins to precipitate from  $0.10 \text{ M NH}_3$ .  $K_{sp}$  for  $\text{Mg}(\text{OH})_2$  is  $1.8 \times 10^{-11}$ .

**17.96** Hydrazine,  $\text{N}_2\text{H}_4$ , is a base that ionizes to give  $\text{N}_2\text{H}_5^+$  and  $\text{OH}^-$  ( $K_b = 1.7 \times 10^{-6}$ ). You add magnesium sulfate to a hydrazine solution. Calculate the concentration of  $\text{Mg}^{2+}$  ion when magnesium hydroxide,  $\text{Mg}(\text{OH})_2$ , just begins to precipitate from  $0.20 \text{ M N}_2\text{H}_4$ .  $K_{sp}$  for  $\text{Mg}(\text{OH})_2$  is  $1.8 \times 10^{-11}$ .

**17.97** A saturated solution of copper(II) iodate in pure water has a copper-ion concentration of  $2.7 \times 10^{-3} \text{ M}$ .

**a** What is the molar solubility of copper iodate in a  $0.35 \text{ M}$  potassium iodate solution?

**b** What is the molar solubility of copper iodate in a  $0.35 \text{ M}$  copper nitrate solution?

**c** Should there be a difference in the answers to parts a and b? Why?

**17.98** A saturated solution of lead iodate in pure water has an iodate-ion concentration of  $8.0 \times 10^{-5} \text{ M}$ .

**a** What is the molar solubility of lead iodate in a  $0.15 \text{ M}$  lead nitrate solution at the same temperature?

**b** Should the molar solubility of lead iodate in part a be the same as, greater than, or less than that of lead iodate in pure water? Why?

**17.99** A solution contains  $0.0150 \text{ M}$  lead(II) ion. A concentrated sodium iodide solution is added dropwise to precipitate lead iodide (assume no volume change).

**a** At what concentration of  $\text{I}^-$  does precipitate start to form?

**b** When  $[\text{I}^-] = 2.0 \times 10^{-3} \text{ M}$ , what is the lead-ion concentration? What percentage of the lead(II) originally present remains in solution?

**17.100** A solution contains  $0.00740 \text{ M}$  calcium ion. A concentrated sodium fluoride solution is added dropwise to precipitate calcium fluoride (assume no volume change).

**a** At what concentration of  $\text{F}^-$  does precipitate start to form?

**b** When  $[\text{F}^-] = 9.5 \times 10^{-4} \text{ M}$ , what is the calcium-ion concentration? What percentage of the calcium ion has precipitated?

**17.101** **a** If the molar solubility of cobalt(II) hydroxide is  $5.4 \times 10^{-6} \text{ mol/L}$  in pure water, what is its  $K_{sp}$  value?

**b** What is the molar solubility of  $\text{Co}(\text{OH})_2$  in a buffered solution that has a pH of 10.43?

**c** Account for the differences in molar solubility in parts a and b.

**17.102** **a** If the molar solubility of beryllium(II) hydroxide is  $8.6 \times 10^{-7} \text{ M}$  in pure water, what is its  $K_{sp}$  value?

**b** What is the molar solubility of beryllium(II) hydroxide in a solution that is  $1.50 \text{ M}$  in  $\text{NH}_3$  and  $0.25 \text{ M}$  in  $\text{NH}_4\text{Cl}$ ?

**c** Account for the differences in molar solubility in parts a and b.

**17.103** Although silver chloride is insoluble in water, it readily dissolves upon the addition of ammonia.

**a** What is the equilibrium constant for this dissolving process?

**b** Ammonia is added to a solution containing excess  $\text{AgCl}(s)$ . The final volume is  $1.00 \text{ L}$  and the resulting

equilibrium concentration of  $\text{NH}_3$  is  $0.80\text{ M}$ . Calculate the number of moles of  $\text{AgCl}$  dissolved, the molar concentration of  $\text{Ag}(\text{NH}_3)_2^+$ , and the number of moles of  $\text{NH}_3$  added to the original solution.

**17.104** Crystals of  $\text{AgBr}$  can be removed from black-and-white photographic film by reacting the  $\text{AgBr}$  with sodium thiosulfate.

- a** What is the equilibrium constant for this dissolving process?  
**b** In order to dissolve  $2.5\text{ g}$  of  $\text{AgBr}$  in  $1.0\text{ L}$  of solution, how many moles of  $\text{Na}_2\text{S}_2\text{O}_3$  must be added?

**17.105** A  $1.0\text{-L}$  solution that is  $4.2\text{ M}$  in ammonia is mixed with  $26.7\text{ g}$  of ammonium chloride.

- a** What is the hydroxide-ion concentration of this solution?

- b**  $0.075\text{ mol}$  of  $\text{MgCl}_2$  is added to the above solution. Assume that there is no volume change. After  $\text{Mg}(\text{OH})_2$  has precipitated, what is the molar concentration of magnesium ion? What percent of the  $\text{Mg}^{2+}$  is removed from solution?

**17.106** A  $1.0\text{-L}$  solution that is  $1.6\text{ M}$  in ammonia is mixed with  $75.8\text{ g}$  of ammonium sulfate.

- a** What is the hydroxide-ion concentration of this solution?  
**b**  $0.058\text{ mol}$  of  $\text{MnCl}_2$  is added to the above solution. Assume that there is no volume change. After  $\text{Mn}(\text{OH})_2$  has precipitated, what is the molar concentration of manganese ion? What percent of the  $\text{Mn}^{2+}$  is removed from solution ( $K_{sp}$  of  $\text{Mn}(\text{OH})_2$  is  $4.6 \times 10^{-14}$ )?

**17.107** What chemical reaction is responsible for the dissolving out of caverns in limestone caves?

**17.108** What chemical reaction is responsible for the formation of stalactites and stalagmites in limestone caves? How is this reaction related to the one involved in the dissolving out of caverns?

## Strategy Problems

**Key:** As noted earlier, all of the practice and general problems are matched pairs. This section is a selection of problems that are not in matched-pair format. These challenging problems require that you employ many of the concepts and strategies that were developed in the chapter. In some cases, you will have to integrate several concepts and operational skills in order to solve the problem successfully.

**17.109** You add  $50.0\text{ mL}$  of  $0.100\text{ M HCl}$  to  $50.0\text{ mL}$  of  $0.100\text{ M AgNO}_3$ . What are the final concentrations of  $\text{H}_3\text{O}^+$  and  $\text{Cl}^-$  in the solution?

**17.110** A chemist mixes  $1.00\text{ L}$  each of  $0.100\text{ M Na}_2\text{CO}_3$  and  $0.200\text{ M CaCl}_2$  in a beaker. What is the concentration of carbonate ion,  $\text{CO}_3^{2-}$ , in the final solution?

**17.111** A researcher found the solubility of lead(II) bromide in  $0.100\text{ M NaBr}$  to be  $1.31\text{ g/L}$ . What is the solubility product of lead(II) bromide?

**17.112** Gout is a painful inflammation of the joints caused by an excess of uric acid in the blood and its precipitation as sodium urate (the sodium salt of uric acid),  $\text{NaC}_5\text{H}_3\text{N}_4\text{O}_3$ , in tissues of the joints. The solubility of sodium urate in aqueous solution is  $7.0\text{ mg}$  per  $100\text{ mL}$  at body temperature,  $37^\circ\text{C}$ . The normal level of sodium ion in blood plasma is  $3.2\text{ g}$  per liter. What would be the concentration of urate ion in blood plasma if it were saturated with sodium urate?

**17.113** An analytical chemist has a solution containing chloride ion,  $\text{Cl}^-$ . She decides to determine the amount of chloride ion in the solution by titrating  $50.0\text{ mL}$  of this solution by  $0.100\text{ M AgNO}_3$ . As a way to indicate the end-point of the titration, she added  $1.00\text{ g}$  of potassium chromate,  $\text{K}_2\text{CrO}_4$  (see Figure 17.5). As she slowly added the silver nitrate to the solution, a white precipitate formed. She continued the titration, with more white precipitate forming. Finally, the solution turned red, from another precipitate. The volume of the solution at this point was  $60.3\text{ mL}$ . How many moles of chloride ion were there in the original solution? How many moles of chloride ion were there in the final solution? You may make any reasonable approximations.

**17.114** How would the solubility of calcium fluoride be affected by the presence of fluoride ion from another source? What is the solubility of calcium fluoride in a saturated solution of barium fluoride? How does this compare with the value of the solubility of calcium fluoride found in Example 17.4? Is this what you expect?

**17.115** A scientist was interested in how soluble rust is in acidic soils, so she set up an idealized problem to get an initial feel for the situation. A fairly acidic soil has a pH of  $4.50$ . Also, rust is essentially  $\text{Fe}(\text{OH})_3$ . Therefore, she considered the following problem: Suppose a  $1.00\text{-g}$  sample of iron(III) hydroxide is exposed to  $1.00\text{ L}$  of a buffer with a pH of  $4.50$ . She then calculated the nanograms of  $\text{Fe}^{3+}$  that dissolve in a liter of this buffer. Show how you would do this problem. Explain your work.

**17.116** A  $1.00\text{-g}$  sample of solid barium sulfate and a similar  $1.00\text{-g}$  sample of solid calcium sulfate were added to water at  $25^\circ\text{C}$  to give  $1.00\text{ L}$  of solution. Calculate the concentrations of  $\text{Ba}^{2+}$ ,  $\text{Ca}^{2+}$ , and  $\text{SO}_4^{2-}$  ions present in the solution.

**17.117** Calcium fluoride,  $\text{CaF}_2$ , is a very slightly soluble salt. In Example 17.4, we calculated its solubility from the solubility constant, assuming that the solubility equilibrium represented by  $K_{sp}$  was the only important one. However, a solution of the salt does contain the species  $\text{HF}$ . Where does

this come from? Would you expect this to increase or decrease the solubility as we calculated it in the example? Using the fluoride-ion concentration that we calculated in the example, obtain the concentration of HF in the solution. From this, decide how important the formation of fluoride ion is in determining the solubility of calcium fluoride. Without doing any calculations, decide how important you think a similar effect would be in determining the solubility of calcium carbonate. Explain.

**17.118** You slowly add ammonia,  $\text{NH}_3$ , to 1.00 L of water containing 5.00 g of solid nickel(II) iodate,  $\text{Ni}(\text{IO}_3)_2$ . How much ammonia (in moles) would you have to add to just dissolve the nickel(II) iodate? What would be the molar concentration of ammonia in the solution at that point?  $K_{sp}$  for nickel iodate is  $1.4 \times 10^{-8}$ .

**17.119** A chemist mixes equal volumes of 0.10 M  $\text{CaCl}_2$  and 0.15 M  $\text{NaF}$  in a beaker. What are the concentrations of  $\text{Ca}^{2+}$ ,  $\text{Na}^+$ ,  $\text{Cl}^-$ , and  $\text{F}^-$  in the solution in the beaker at 25°C?

**17.120** Suppose you add 35.6 mL of 0.578 M  $\text{H}_2\text{SO}_4$  to 55.6 mL of 0.491 M  $\text{Ba}(\text{OH})_2$ . What would be the concentrations of  $\text{Ba}^{2+}$  and  $\text{SO}_4^{2-}$  in the final solution at 25°C? What would be the pH of this solution?

**17.121** Suppose you add 35.6 mL of 0.578 M  $\text{Ba}(\text{OH})_2$  to 55.6 mL of 0.491 M  $\text{H}_2\text{SO}_4$ . What would be the concentrations of  $\text{Ba}^{2+}$  and  $\text{SO}_4^{2-}$  in the final solution at 25°C? What would be the pH of this solution?

**17.122** What volume of water would be required to dissolve 10.0 g of silver chloride,  $\text{AgCl}$ , at 25°C? What volume of 0.15 M  $\text{NH}_3$  would be required to dissolve the same quantity of silver chloride?

**17.123** Natural water is said to be “hard” when it contains metal ions such as  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  that interfere with the use of detergents. These ions are often present in natural

water as the soluble hydrogen carbonates,  $\text{Ca}(\text{HCO}_3)_2$  and  $\text{Mg}(\text{HCO}_3)_2$ . One way to remove these ions from natural water is to add lime,  $\text{Ca}(\text{OH})_2$ , to it. This addition of a calcium compound may seem paradoxical. What happens to a solution of calcium hydrogen carbonate when the pH is raised? Does this solve the paradox? Explain.

**17.124** Suppose you have a water solution that is 0.0010 M  $\text{Ca}^{2+}$  and 0.0010 M  $\text{Mg}^{2+}$ . Describe the precipitation reactions as you slowly add a concentrated solution of sodium carbonate,  $\text{Na}_2\text{CO}_3$ , to this solution. What would be the concentration of carbonate ion,  $\text{CO}_3^{2-}$ , when at least 90.0% of  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  have been precipitated.

**17.125** Magnesium metal is produced from seawater that contains magnesium ion,  $\text{Mg}^{2+}$ ; seawater contains 1.35 mg of magnesium ion per liter. Magnesium ion is precipitated from seawater by adding calcium hydroxide,  $\text{Ca}(\text{OH})_2$ , to it. (Calcium hydroxide can be obtained from seashells, which are mostly calcium carbonate.) What would be the pH of the seawater after 90.0% of the magnesium ion has been precipitated by calcium hydroxide? How many grams of  $\text{Ca}(\text{OH})_2$  would have to be added per liter of seawater to precipitate this percentage of magnesium ion?

**17.126** Suppose that an aqueous solution is in equilibrium with solid calcium sulfate and solid barium sulfate. What are the concentrations of calcium ion and barium ion in the solution?

**17.127** Solid magnesium hydroxide,  $\text{Mg}(\text{OH})_2$ , is added to a solution that is 1.00 M  $\text{NH}_4\text{Cl}$ . What is the concentration of  $\text{Mg}^{2+}$  in this solution at equilibrium?

**17.128** The text describes zinc hydroxide as an amphoteric hydroxide, so  $\text{Zn}(\text{OH})_2$  is soluble in basic solution. What is the molar solubility of  $\text{Zn}(\text{OH})_2$  in 1.00 M  $\text{NaOH}$ ? What is the pH of the equilibrium solution?

## Capstone Problems

**Key:** The problems under this heading combine skills, strategies, and concepts learned in previous chapters with those introduced in the current one.

**17.129** A solution is  $1.5 \times 10^{-4}$  M  $\text{Zn}^{2+}$  and 0.20 M  $\text{HSO}_4^-$ . The solution also contains  $\text{Na}_2\text{SO}_4$ . What should be the minimum molarity of  $\text{Na}_2\text{SO}_4$  to prevent the precipitation of zinc sulfide when the solution is saturated with hydrogen sulfide (0.10 M  $\text{H}_2\text{S}$ )?

**17.130** A solution is  $1.8 \times 10^{-4}$  M  $\text{Co}^{2+}$  and 0.20 M  $\text{HSO}_4^-$ . The solution also contains  $\text{Na}_2\text{SO}_4$ . What should be the minimum molarity of  $\text{Na}_2\text{SO}_4$  to prevent the precipitation of cobalt(II) sulfide when the solution is saturated with hydrogen sulfide (0.10 M  $\text{H}_2\text{S}$ )?

**17.131** What is the solubility of calcium fluoride in a buffer solution containing 0.45 M  $\text{HCHO}_2$  (formic acid) and

0.20 M  $\text{NaCHO}_2$ ? (*Hint:* Consider the equation  $\text{CaF}_2(\text{s}) + 2\text{H}^+(\text{aq}) \rightleftharpoons \text{Ca}^{2+}(\text{aq}) + 2\text{HF}(\text{aq})$ , and solve the equilibrium problem.)

**17.132** What is the solubility of magnesium fluoride in a buffer solution containing 0.45 M  $\text{HC}_2\text{H}_3\text{O}_2$  (acetic acid) and 0.20 M  $\text{NaC}_2\text{H}_3\text{O}_2$ ? The  $K_{sp}$  for magnesium fluoride is  $6.5 \times 10^{-9}$ . (See the hint for Problem 17.131.)

**17.133** A 67.0-mL sample of 0.350 M  $\text{MgSO}_4$  is added to 45.0 mL of 0.250 M  $\text{Ba}(\text{OH})_2$ . What is the net ionic equation for the reaction that occurs? What are the concentrations of ions in the mixture at equilibrium?

**17.134** A 50.0-mL sample of 0.0150 M  $\text{Ag}_2\text{SO}_4$  is added to 25.0 mL of 0.0100 M  $\text{PbCl}_2$ . What is the net ionic equation for the reaction that occurs? What are the concentrations of ions in the mixture at equilibrium?

## CONTENTS AND CONCEPTS

**18.1** First Law of Thermodynamics: A Review**Spontaneous Processes and Entropy**

A spontaneous process is one that occurs by itself. As we will see, the entropy of a system and its surroundings increases in a spontaneous process.

**18.2** Entropy and the Second Law of Thermodynamics**18.3** Standard Entropies and the Third Law of Thermodynamics**Free-Energy Concept**

In Section 18.2, we showed that the quantity  $\Delta H - T\Delta S$  can function as a criterion for the spontaneity of a reaction at constant temperature,  $T$ , and pressure,  $P$ . By defining a quantity called the free energy  $G = H - TS$ , we find that  $\Delta G$  equals this quantity  $\Delta H - T\Delta S$ , so the free energy gives us a thermodynamic criterion of spontaneity.

**18.4** Free Energy and Spontaneity**18.5** Interpretation of Free Energy**Free Energy and Equilibrium Constants**

The total free energy of the substances in a reaction mixture decreases as the reaction proceeds. As we discuss, the standard free-energy change for a reaction is related to its equilibrium constant.

**18.6** Relating  $\Delta G^\circ$  to the Equilibrium Constant**18.7** Change of Free Energy with Temperature

**U**rea,  $\text{NH}_2\text{CONH}_2$ , is an important industrial chemical. It is used to make synthetic resins for adhesives and melamine plastics (Figure 18.1). Its major use, however, is as a nitrogen fertilizer for plants. Urea is produced by reacting ammonia with carbon dioxide. We can write the overall reaction as:

Suppose you want to determine whether this or some other reaction could be useful for the industrial preparation of urea. Some of your immediate questions might be the following: Does the reaction naturally go in the direction it is written? Will the reaction mixture contain a sufficient amount of the product at equilibrium? We addressed these questions in the preceding chapters by looking at the equilibrium constant. Now we want to discuss these questions from the point of view of thermodynamics.

*Thermodynamics* is the study of the relationship between heat and other forms of energy involved in a chemical or physical process. With only heat measurements of substances, you can answer the questions just posed. You can predict the natural direction of a chemical reaction, and you can also determine the composition of a reaction mixture at equilibrium. Consider, then, the possibility of reacting  $\text{NH}_3$  and  $\text{CO}_2$  to give urea. Just how do you apply thermodynamics to such a reaction?

### 18.1 First Law of Thermodynamics: A Review

Thermodynamics is described in terms of three laws. *The first law of thermodynamics* is essentially the law of conservation of energy applied to thermodynamic systems. The law of conservation of energy, you may recall, says that the total energy remains constant.

#### Mathematical Statement of the First Law

In a thermodynamic system, the sum of the kinetic and potential energies of the particles making up the system is referred to as its *internal energy*,  $U$ . The internal energy can change as the result of transfers of energy (or energy flows) into or out of the system, and the first law simply says that the change of internal energy equals the sum of these energy transfers.

These transfers, or flows of energy, are of two kinds: heat,  $q$ , and work,  $w$ . If a chemical reaction occurs in the system, *heat of reaction* may evolve or perhaps be absorbed. Energy as heat leaves or enters the system. The system may also do work on the surroundings or have work done on it by the surroundings. *Pressure-volume work* is a common form of work.

$$\text{Pressure-volume work} = -P\Delta V$$

Suppose the volume,  $V$ , of the system increases so that the system pushes against the external pressure of the atmosphere,  $P$ . Effectively the system lifts the atmosphere against gravity and does work on it. In doing this work, energy leaves the system (flows out of it) and goes into the surroundings. Or perhaps the volume of the system decreases so that the external pressure pushes against the system. In this case, work is done on the system; energy flows from the surroundings to the system.

According to the first law of thermodynamics, whenever a thermodynamic system undergoes a physical or chemical change, the change of internal energy,  $\Delta U$ , of the system equals the sum of the heat,  $q$ , and work done,  $w$ , in that physical or chemical change.

$$\Delta U = q + w$$

#### Enthalpy of Reaction

When a physical or chemical change occurs against a constant external pressure, as would happen when the change occurs in a flask open to the atmosphere, it is useful to define the thermodynamic quantity called *enthalpy*,  $H$ . The enthalpy of a system is defined as the system's internal energy plus pressure times volume; it is a state

**Figure 18.1** ▲  
Urea

function since  $U$ ,  $P$ , and  $V$  are state functions. A state function is a property of a system that depends only on its present state, which is determined by variables such as temperature and pressure.

$$H = U + PV$$

With this definition, one can show that the heat involved in a physical or chemical change for a given fixed pressure and temperature simply equals the change in enthalpy for the system.

$$q = \Delta H$$

It is useful to tabulate *standard enthalpies of formation*,  $\Delta H_f^\circ$ , for substances. Appendix C lists values at 25°C and 1 atm pressure for selected substances. Using these values, you can calculate the standard enthalpy change for a reaction, which equals the heat of reaction.

$$\Delta H^\circ = \sum n\Delta H_f^\circ(\text{products}) - \sum m\Delta H_f^\circ(\text{reactants})$$

Consider the reaction between  $\text{NH}_3$  and  $\text{CO}_2$  to produce urea and water, which is the reaction given in the chapter opening.

The standard enthalpies of formation at 25°C for these substances are (in kJ/mol):  $\text{NH}_3(g)$ ,  $-45.9$ ;  $\text{CO}_2(g)$ ,  $-393.5$ ;  $\text{NH}_2\text{CONH}_2(aq)$ ,  $-319.2$ ; and  $\text{H}_2\text{O}(l)$ ,  $-285.8$ . Substituting these values into the equation for the standard enthalpy change yields

$$\Delta H^\circ = [(-319.2 - 285.8) - (-2 \times 45.9 - 393.5)] \text{ kJ} = -119.7 \text{ kJ}$$

From the minus sign of  $\Delta H^\circ$ , you can conclude that heat is evolved. The reaction is exothermic.

## ► Spontaneous Processes and Entropy

Why does a chemical reaction go naturally in a particular direction? To answer this question, we need to look at spontaneous processes. A **spontaneous process** is a *physical or chemical change that occurs by itself*. It requires no continuing external force to make it happen. A rock at the top of a hill rolls down (Figure 18.2, *top*). Heat flows from a hot object to a cold one. An iron object rusts in moist air (Figure 18.3). These processes occur spontaneously, or naturally, without requiring an outside force. They continue until equilibrium is reached. If these processes were to go in the opposite

**Figure 18.2** ►  
Examples of a spontaneous  
and a nonspontaneous  
process

direction, they would be *nonspontaneous*. They would require the application of an external force. The rolling of a rock uphill by itself is not a natural process; it is nonspontaneous (see Figure 18.2, *bottom*). The rock could be moved to the top of the hill, but work would have to be expended. Heat can be made to flow from a cold to a hot object, but a heat pump or refrigerator is needed. Rust can be converted to iron, but the process requires chemical reactions used in the manufacture of iron from its ore (iron oxide).

## 18.2 Entropy and the Second Law of Thermodynamics

When you ask whether a chemical reaction goes in the direction in which it is written, as we did in the chapter opening, you are asking whether the reaction is spontaneous in this direction. The first law of thermodynamics cannot help you answer such a question. It does help you keep track of the various forms of energy in a chemical change, using the constancy of total energy (conservation of energy). But although at one time it was thought that spontaneous reactions must be exothermic ( $\Delta H < 0$ ), many spontaneous reactions are now known to be endothermic ( $\Delta H > 0$ ); recall the reaction shown in Figure 6.1, in which barium hydroxide octahydrate reacts with an ammonium salt.

The second law of thermodynamics, which we will discuss in this section, provides a way to answer questions about the spontaneity of a reaction. The second law is expressed in terms of a quantity called *entropy*.

### Entropy

**Entropy,  $S$ ,** is a thermodynamic quantity that is a measure of how dispersed the energy of a system is among the different possible ways that system can contain energy. When the energy of a thermodynamic system is concentrated in a relatively few energy states, the entropy of the system is low. When that same energy, however, is dispersed or spread out over a great many energy states, the entropy of the system is high. What you will see is that the entropy (energy dispersal) of a system plus its surroundings increases in a spontaneous process.

Let's look at some simple spontaneous processes. Suppose you place a hot cup of coffee on the table. Heat energy from the hot coffee flows slowly to the table and to the air surrounding the cup. In this process, energy spreads out or disperses. The entropy of the system (coffee cup) and its surroundings (table and surrounding air) increases in this spontaneous process.

As a slightly more complicated example, consider a rock at the top of a hill. The rock has potential energy relative to what it would have at the bottom of the hill. Imagine the rock rolling downhill. As it does so, its potential energy changes to kinetic energy, and during its descent atoms of the rock collide with those of the hillside and surrounding air, dispersing energy from the rock to its surroundings. The entropy of the system (rock) plus its surroundings (hillside and surrounding air) increases in this spontaneous process.

As a final example, imagine a flask containing a gas connected to an evacuated flask by a valve or stopcock (Figure 18.4). When the valve is opened, gas in the flask flows into the space of the evacuated flask. In this case, the kinetic energy of the gas molecules spreads out or disperses over the volumes of both flasks. The

**Figure 18.3** ▲

**The rusting of iron in moist air is a spontaneous reaction** This sculpture by Picasso in Chicago (Daley Plaza) was allowed to rust to give a pleasing effect.

**Figure 18.4** ◀

**Expansion of a gas into a vacuum** Initially, the flask on the left contains a gas, whereas the flask on the right is evacuated. Then the valve is opened and gas spontaneously flows into the evacuated flask (the vacuum).

entropy of this system (both flasks) increases in this spontaneous process. In this case, we assume that the surroundings do not participate in the overall change (there is no entropy change in the surroundings); the entropy change occurs entirely within the system.

In each of these spontaneous processes, energy has been dispersed, or spread out. The entropy of the system plus surroundings has increased.

As we will discuss later, the SI unit of entropy is joules per kelvin (J/K). Entropy, like enthalpy, is a state function. That is, the quantity of entropy in a given amount of substance depends only on variables, such as temperature and pressure, that determine the state of the substance. If these variables are fixed, the quantity of entropy is fixed. For example, 1 mol of ice at 0°C and 1 atm pressure has an entropy that has been determined experimentally to be 41 J/K. One mole of liquid water at 0°C and 1 atm has an entropy of 63 J/K. (In the next section, we will describe how you measure these values.) Why is the entropy of liquid water higher than that of solid water (ice)? In an ice crystal, water molecules occupy regular fixed positions in the crystal lattice. Molecules can vibrate or oscillate about these fixed positions, but otherwise are restricted in their motions, and therefore the energies available to them. In the liquid state, water molecules can rotate as well as vibrate internally and can move around somewhat (though not as freely as molecules can move in the gaseous state). Thus, the entropy of liquid water is expected to be higher than that of ice—the energy is dispersed over more available energy states in the liquid.

You calculate the entropy change,  $\Delta S$ , for a process similarly to the way you calculate  $\Delta H$ . If  $S_i$  is the initial entropy and  $S_f$  is the final entropy, the change in entropy is

$$\Delta S = S_f - S_i$$

For the melting of ice to liquid water,

$$\Delta S = (63 - 41) \text{ J/K} = 22 \text{ J/K}$$

When 1 mol of ice melts at 0°C, the water increases in entropy by 22 J/K. The entropy increases, as you expect, because the energy of water becomes more dispersed when it melts.

### ✓ CONCEPT CHECK 18.1

You have a sample of 1.0 mg of solid iodine at room temperature. Later, you notice that the iodine has sublimed (passed into the vapor state). What can you say about the change of entropy of the iodine?

## Second Law of Thermodynamics

A process occurs naturally as a result of the dispersal of energy in the system plus surroundings. We can state this precisely in terms of the **second law of thermodynamics**, which states that *the total entropy of a system and its surroundings always increases for*

*a spontaneous process.* Note that entropy (energy dispersal) is quite different from energy itself. Energy can be neither created nor destroyed during a spontaneous, or natural, process—its total amount remains fixed. But energy is dispersed in a spontaneous process, which means that entropy is produced (or created) during such a process.

For a spontaneous process carried out at a given temperature, the second law can be restated in a form that refers only to the system (and not to the system plus surroundings, as in the previous statement of the second law). We will find this new statement particularly useful in analyzing chemical problems.

Suppose a spontaneous process occurs within a system that is in thermal contact with its surroundings at a given temperature  $T$ —say, a chemical reaction in a flask. As the chemical reaction occurs, entropy is produced (or created) within the system (the flask) as a result of this spontaneous process. At the same time, heat might flow into or out of the system as a result of the thermal contact. (In other words, the reaction may be endothermic or exothermic.) *Heat flow is also a flow of entropy, because it is a dispersal of energy*, either into the flask or outside of it. In general, the entropy change associated with a flow of heat  $q$  at an absolute temperature  $T$  can be shown to equal  $q/T$ . The *net change* of entropy in the system (in the flask) is the entropy created during the spontaneous chemical reaction that occurs plus the entropy change that is associated with the heat flow (entropy flow).

$$\Delta S = \text{entropy created} + \frac{q}{T}$$

It might be helpful to consider an analogy. A baker makes (creates) cookies at her store (the system). She also buys cookies from a wholesaler and sells cookies at her store. The change in number of cookies in her store in any given interval of time equals the number made (number created) plus the number bought minus the number sold (flow of cookies into or out of her store). We obtain an equation similar to the one we wrote for the entropy change,  $\Delta S$ .

Change of cookies in store = cookies created + flow of cookies into or out of store

However, our analogy breaks down if someone eats cookies in the store. Whereas entropy can only be created, cookies can be created and destroyed (eaten).

The quantity of entropy created during a spontaneous process is a positive quantity—the entropy increases as it is created. If we delete “entropy created” from the right side of the equation for  $\Delta S$ , we know that the left side is then greater than the right side:

$$\Delta S > \frac{q}{T}$$

We can now restate the second law as follows:

**Second Law of Thermodynamics:** *For a spontaneous process at a given temperature  $T$ , the change in entropy of the system is greater than the heat divided by the absolute temperature,  $q/T$ .*

### Entropy and Molecular Disorder

Fundamentally, entropy is related to energy dispersal. The energy of a molecular system may at first be concentrated in a few energy states and then later dispersed among many more energy states. In such a case, the entropy of the system increases. You might also say that the molecular system has increased in “disorder,” in the sense that the energy is strewn or distributed over many energy states, rather than concentrated in a few energy states.

Consider the pendulum depicted in Figure 18.5. Suppose you start the pendulum by moving it upward and releasing it. The pendulum begins to swing to and fro.

**Figure 18.5** ▲

**Motion of a pendulum** *A* to *C* depicts the spontaneous motion of the pendulum. *D* to *F* depicts the nonspontaneous motion of a pendulum.

On each swing, it moves through a smaller and smaller arc, eventually coming to rest. While the pendulum is moving, its atoms have a concerted motion, which is the kinetic energy of the pendulum (Figure 18.5a). All of the atoms of the pendulum are moving in the same direction, though with small oscillational motions (or thermal motions) superimposed on this concerted motion. As these atoms collide with molecules of the surrounding air, however, some of this concerted motion is transferred to the random motion of air molecules (Figure 18.5b). Air molecules buffeted by the pendulum begin to move with it, but soon, their motions become random as they collide with many other air molecules. The molecular motion becomes more disordered. Eventually, the pendulum comes to rest with its energy dispersed, partly to the surrounding air (Figure 18.5c). Entropy has increased.

Imagine that you had captured this motion on film or video, and later you show this film in reverse. The pendulum, initially at rest, begins to swing through larger and larger arcs. This motion is clearly not what you would expect to see. A pendulum at rest does not spontaneously begin to move to and fro. Let's look at this process in molecular detail. At first the pendulum is at rest with surrounding molecules of air in random motion (Figure 18.5d). Then, by chance a large number of air molecules gather together to buffet the stationary pendulum (Figure 18.5e). Molecules of air, at first moving randomly, begin to move together, and start the pendulum moving upward (Figure 18.5f). What does thermodynamics have to say

about this process? Note that this process does not violate the first law; energy remains constant; it merely exchanges from one molecule to another. This process does violate the second law, however. Energy dispersed over many energy states (molecules moving randomly) becomes more concentrated in those states in which the molecules move together. A disordered state becomes ordered, and entropy decreases. This process is nonspontaneous.

Let's look at a few other examples. Earlier we considered the cooling of a cup of coffee. Heat moves from the hot coffee to its surroundings. Molecular motion becomes more disordered, in the sense that it is dispersed over a larger volume. Similarly, when a gas flows from a flask into a connected evacuated flask, molecules become more disordered in the sense that they are strewn over a larger volume. When ice melts, water molecules leave an ordered crystal and enter a more disordered liquid state. As a final example, consider the chemical reaction in which dinitrogen tetroxide,  $\text{N}_2\text{O}_4$ , dissociates into two nitrogen dioxide molecules,  $\text{NO}_2$ :

The reaction, in breaking one molecule into two smaller ones, creates more disorder in the sense that the two  $\text{NO}_2$  molecules can now move independently. In each of these changes, molecular disorder increases, as does entropy.

Unfortunately, the picture of entropy as a measure of disorder has been misapplied to situations that are not molecular. For example, imagine your desk with books and papers placed carefully to give an "orderly" arrangement. Later, as you work, your books and papers become strewn about—your desk becomes disordered. This has sometimes been described as a spontaneous process in which entropy increases. Of course, the books and papers do not move spontaneously—you move them. In fact, there is essentially no difference between the thermodynamic entropies of the ordered and disordered desks. All that has happened is that normal-sized objects (books and papers) have been moved by you from human-defined order to human-defined disorder.

Again, fundamentally entropy is related to the dispersal of energy. The entropy of a system can be defined rigorously by the methods of *statistical thermodynamics* in terms of a sum over the energy levels available to the system. The picture of thermodynamic entropy as disorder may sometimes be useful, but it should be applied carefully to molecular systems.

### Entropy Change for a Phase Transition

Certain processes occur at equilibrium or, more precisely, very close to equilibrium. For example, ice at  $0^\circ\text{C}$  is in equilibrium with liquid water at  $0^\circ\text{C}$ . If heat is slowly absorbed by the system, it remains very near equilibrium, but the ice melts. Under these essentially equilibrium conditions, no significant amount of entropy is created. The entropy change results entirely from the absorption of heat. Therefore,

$$\Delta S = \frac{q}{T} \quad \text{(equilibrium process)}$$

Other phase changes, such as the vaporization of a liquid, also occur under equilibrium conditions. ▶

You can use the previous equation to obtain the entropy change for a phase change. Consider the melting of ice. The heat absorbed is the heat of fusion,  $\Delta H_{fus}$ , which is known from experiment to be 6.0 kJ for 1 mol of ice. You get the entropy change for melting by dividing  $\Delta H_{fus}$  by the absolute temperature of the phase transition, 273 K ( $0^\circ\text{C}$ ). Because entropy changes are usually expressed in joules per kelvin, you convert  $\Delta H_{fus}$  to  $6.0 \times 10^3$  J.

$$\Delta S = \frac{\Delta H_{fus}}{T} = \frac{6.0 \times 10^3 \text{ J}}{273 \text{ K}} = 22 \text{ J/K}$$

Note that this is the  $\Delta S$  value we obtained earlier for the conversion of ice to water.

When a system is at equilibrium, a small change in a condition can make the process go in one direction or the other. The process is said to be *reversible*. Think of a two-pan balance in which the weight on each pan has been adjusted to make the balance beam level—that is, so the beam is at equilibrium. A small weight on either pan will tip the scale one way or the other.

**Example 18.1** Calculating the Entropy Change for a Phase Transition**Gaining Mastery Toolbox****Critical Concept 18.1**

The entropy change for an equilibrium process at a given temperature and pressure such as a phase transition equals the enthalpy change divided by the absolute temperature.

**Solution Essentials:**

- Entropy,  $S$
- Enthalpy change for a phase transition (Example:  $\Delta H_{\text{vap}}^\circ$ )
- Phase transition
- Enthalpy of reaction,  $\Delta H$

The heat of vaporization,  $\Delta H_{\text{vap}}$ , of carbon tetrachloride,  $\text{CCl}_4$ , at  $25^\circ\text{C}$  is  $39.4 \text{ kJ/mol}$ .

If 1 mol of liquid carbon tetrachloride at  $25^\circ\text{C}$  has an entropy of  $216 \text{ J/K}$ , what is the entropy of 1 mol of the vapor in equilibrium with the liquid at this temperature?

**Problem Strategy** The entropy change for this equilibrium vaporization is  $\Delta H_{\text{vap}}/T$ . The entropy of the vapor equals the entropy of the liquid plus the entropy change.

**Solution** When liquid  $\text{CCl}_4$  evaporates, it absorbs heat:  $\Delta H_{\text{vap}} = 39.4 \text{ kJ/mol}$  ( $39.4 \times 10^3 \text{ J/mol}$ ) at  $25^\circ\text{C}$ , or  $298 \text{ K}$ . The entropy change,  $\Delta S$ , is

$$\Delta S = \frac{\Delta H_{\text{vap}}}{T} = \frac{39.4 \times 10^3 \text{ J/mol}}{298 \text{ K}} = 132 \text{ J/(mol}\cdot\text{K)}$$

In other words, 1 mol of carbon tetrachloride increases in entropy by  $132 \text{ J/K}$  when it vaporizes. The entropy of 1 mol of the vapor equals the entropy of 1 mol of liquid ( $216 \text{ J/K}$ ) plus  $132 \text{ J/K}$ .

$$\text{Entropy of vapor} = (216 + 132)\text{J/(mol}\cdot\text{K)} = \mathbf{348 \text{ J/(mol}\cdot\text{K)}}$$

Note: This is the entropy at the equilibrium vapor pressure, which differs from  $S^\circ$  (entropy at 1 atm).

**Answer Check** A simple check is to reverse the problem. At equilibrium, the enthalpy change,  $\Delta H$ , equals  $T\Delta S$ .

$$\Delta H = 298 \text{ K} \times 132 \text{ J/(mol}\cdot\text{K)} = 39.3 \times 10^3 \text{ J/mol}$$

This is the enthalpy of vaporization given in the problem statement (within rounding error).

**Exercise 18.1** Liquid ethanol,  $\text{C}_2\text{H}_5\text{OH}(l)$ , at  $25^\circ\text{C}$  has an entropy of  $161 \text{ J/(mol}\cdot\text{K)}$ . If the heat of vaporization,  $\Delta H_{\text{vap}}$ , at  $25^\circ\text{C}$  is  $42.6 \text{ kJ/mol}$ , what is the entropy of the vapor in equilibrium with the liquid at  $25^\circ\text{C}$ ?

See Problems 18.35 and 18.36.

**Criterion for a Spontaneous Reaction**

Now you can see how thermodynamics is applied to the question of whether a reaction is spontaneous. Suppose that you propose a chemical reaction for the preparation of a substance. You also assume that the reaction occurs at constant temperature and pressure. For urea, you propose the reaction

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Is this a spontaneous reaction? That is, does it go left to right as written? You can use the second law in the form  $\Delta S > q/T$  to answer this question if you know both  $\Delta H$  and  $\Delta S$  for the reaction.

Recall that the heat of reaction at constant pressure,  $q_p$ , equals the enthalpy change  $\Delta H$ . The second law for a spontaneous reaction at constant temperature and pressure becomes

$$\Delta S > \frac{q_p}{T} = \frac{\Delta H}{T} \quad (\text{spontaneous reaction, constant } T \text{ and } P)$$

$\Delta S$  is greater than  $\Delta H/T$  for a spontaneous reaction at constant temperature and pressure. Therefore, if you subtract  $\Delta S$  from  $\Delta H/T$ , you get a negative quantity. That is,

$$\frac{\Delta H}{T} - \Delta S < 0 \quad (\text{spontaneous reaction, constant } T \text{ and } P)$$

Multiplying each term of this inequality by the positive quantity  $T$ , you get

$$\Delta H - T\Delta S < 0 \quad (\text{spontaneous reaction, constant } T \text{ and } P)$$

This inequality is important. If you have a table of entropies of substances, you can calculate  $\Delta S$  for the proposed reaction. From Table 6.2, you can also calculate  $\Delta H$ . If  $\Delta H - T\Delta S$  is negative for the reaction, you would predict that it is spontaneous left to right, as written. However, if  $\Delta H - T\Delta S$  is positive, you would predict that the reaction is nonspontaneous in the direction written but spontaneous in the opposite direction. If  $\Delta H - T\Delta S$  is zero, the reaction is at equilibrium.

### 18.3 Standard Entropies and the Third Law of Thermodynamics

To determine experimentally the entropy of a substance, you first measure the heat absorbed by the substance by warming it at various temperatures. That is, you find the heat capacity at different temperatures. ► You then calculate the entropy as we will describe. This determination of the entropy is based on the third law of thermodynamics.

Heat capacity was discussed in Section 6.6.

#### Third Law of Thermodynamics

The **third law of thermodynamics** states that *a substance that is perfectly crystalline at 0 K has an entropy of zero*. This seems reasonable. A perfectly crystalline substance at 0 K should have perfect order. When the temperature is raised, however, the substance increases in entropy as it absorbs heat and energy disperses through it.

You can determine the entropy of a substance at a temperature other than 0 K—say, at 298 K (25°C)—by slowly heating the substance from near 0 K to 298 K. Recall that the entropy change  $\Delta S$  that occurs when heat is absorbed at a temperature  $T$  is  $q/T$ . Suppose you heat the substance from near 0.0 K to 2.0 K, and the heat absorbed is 0.19 J. You find the entropy change by dividing the heat absorbed by the average absolute temperature [ $\frac{1}{2}(0.0 + 2.0)\text{K} = 1.0\text{ K}$ ]. Therefore,  $\Delta S$  equals  $0.19\text{ J}/1.0\text{ K} = 0.19\text{ J/K}$ . This gives you the entropy of the substance at 2.0 K. Now you heat the substance from 2.0 K to 4.0 K, and this time 0.88 J of heat is absorbed. The average temperature is  $\frac{1}{2}(2.0 + 4.0)\text{K} = 3.0\text{ K}$ , and the entropy change is  $0.88\text{ J}/3.0\text{ K} = 0.29\text{ J/K}$ . The entropy of the substance at 4.0 K is  $(0.19 + 0.29)\text{ J/K} = 0.48\text{ J/K}$ . Proceeding this way, you can eventually get the entropy at 298 K. ►

Figure 18.6 shows how the entropy of a substance changes with temperature. Note that the entropy increases gradually as the temperature increases. But when there is a phase change (for example, from solid to liquid), the entropy increases sharply. The entropy change for the phase transition is calculated from the enthalpy of the phase transition, as described earlier (see Example 18.1). The **standard entropy** of a substance or ion (Table 18.1), also called its **absolute entropy**,  $S^\circ$ , is *the entropy value for the standard state of the species* (indicated by the superscript degree sign). For a substance, the standard state is the pure substance at 1 atm pressure. For a species in solution, the standard state is the 1 M solution. Table 18.1 gives standard entropies of various substances at 25°C and 1 atm. Note that the elements have

The process just described is essentially the numerical evaluation of an integral, which you can obtain as follows: The heat absorbed for temperature change  $dT$  is  $C_p(T)dT$ , where  $C_p$  is the heat capacity at constant pressure, and the entropy change is  $C_p(T)dT/T$ . The standard entropy at temperature  $T$  is

$$\int_0^T \frac{C_p(T)dT}{T}$$

Figure 18.6 ◀

**Standard entropy of bromine,  $\text{Br}_2$ , at various temperatures** The entropy rises gradually as the temperature increases, but it jumps sharply at each change of state, say from solid to liquid.

Table 18.1 Standard Entropies (at 25°C)*					
Substance or Ion	$S^\circ$ J/(mol·K)	Substance or Ion	$S^\circ$ J/(mol·K)	Substance or Ion	$S^\circ$ J/(mol·K)

\*See Appendix C for additional values.

nonzero values, unlike standard enthalpies of formation,  $\Delta H_f^\circ$ , which by convention are defined to be zero. The symbol  $S^\circ$ , rather than  $\Delta S^\circ$ , is chosen for standard entropies to emphasize that they originate from the third law. ►

### Entropy Change for a Reaction

Once you determine the standard entropies of all substances in a reaction, you can calculate the change of entropy,  $\Delta S^\circ$ , for the reaction. A sample calculation is described in Example 18.3. Even without knowing values for the entropies of substances, you can sometimes predict the sign of  $\Delta S^\circ$  for a reaction. The entropy usually increases in the following situations:

1. A reaction in which a molecule is broken into two or more smaller molecules.
2. A reaction in which there is an increase in moles of gas. (This may result from a molecule breaking up, in which case Rules 1 and 2 are related.)
3. A process in which a solid changes to liquid or gas or a liquid changes to a gas.

Entropies of substances must be positive. Those for ions, however, can be negative because they are derived in a different way by arbitrarily setting  $S^\circ$  for  $\text{H}_3\text{O}^+(\text{aq})$  equal to zero.

### Example 18.2 Predicting the Sign of the Entropy Change of a Reaction

#### Gaining Mastery Toolbox

##### Critical Concept 18.2

The entropy of a system usually increases during a change that involves one or more of the following processes: a molecule breaks into smaller parts, moles of gas increase, a solid changes to a liquid or a gas, or a liquid changes to a gas. The entropy usually decreases if the change involves a reverse of any of these processes.

##### Solution Essentials:

- Second law of thermodynamics
- Entropy,  $S$

- a. The following equation represents the essential change that takes place during the fermentation of glucose (grape sugar) to ethanol (ethyl alcohol).

Is  $\Delta S^\circ$  positive or negative? Explain.

- b. Do you expect the entropy to increase or decrease in the preparation of urea from  $\text{NH}_3$  and  $\text{CO}_2$ ?

Explain.

- c. What is the sign of  $\Delta S^\circ$  for the following reaction?

**Problem Strategy** Compare the reactants and products in each reaction. Look for the following: molecules breaking into smaller parts or aggregating into larger parts, moles of gas increasing or decreasing, and changes of state. Then apply the three rules preceding this example.

#### Solution

- a. A molecule (glucose) breaks into smaller molecules ( $\text{C}_2\text{H}_5\text{OH}$  and  $\text{CO}_2$ ). Moreover, this results in a gas being released. You predict that  $\Delta S^\circ$  for this reaction is **positive**. That is, the entropy increases.
- b. In this reaction, the moles of gas decrease (by 3 mol), which would decrease the entropy. You predict that the entropy should decrease. That is,  $\Delta S^\circ$  is negative.
- c. Because there is no change in the number of moles of gas, **you cannot predict the sign of  $\Delta S^\circ$  from the rules given.**

**Answer Check** Review the situations listed before this example, and note that the entropy increases whenever a molecule breaks up, moles of gas increase, or a phase change occurs from solid to liquid or from liquid to gas.

**Exercise 18.2** Predict the sign of  $\Delta S^\circ$  for each of the following reactions.

- $\text{CaCO}_3(\text{s}) \longrightarrow \text{CaO}(\text{s}) + \text{CO}_2(\text{g})$
- $\text{CS}_2(\text{l}) \longrightarrow \text{CS}_2(\text{g})$
- $2\text{Hg}(\text{l}) + \text{O}_2(\text{g}) \longrightarrow 2\text{HgO}(\text{s})$
- $2\text{Na}_2\text{O}_2(\text{s}) + 2\text{H}_2\text{O}(\text{l}) \longrightarrow 4\text{NaOH}(\text{aq}) + \text{O}_2(\text{g})$

See Problems 18.39 and 18.40.

It is useful to be able to predict the sign of  $\Delta S^\circ$ . You gain some understanding of the reaction, and you can use the prediction for qualitative work. For quantitative work, however, you need to find the value of  $\Delta S^\circ$ . You can find the standard change of entropy,  $\Delta S^\circ$ , for a reaction by subtracting the standard entropies of reactants from the standard entropies of products, similar to the way you obtained  $\Delta H^\circ$ .

$$\Delta S^\circ = \sum nS^\circ(\text{products}) - \sum mS^\circ(\text{reactants})$$

The next example illustrates the calculations.

### Example 18.3 Calculating $\Delta S^\circ$ for a Reaction

#### Gaining Mastery Toolbox

##### Critical Concept 18.3

You calculate the standard entropy change for a physical or chemical change from the standard entropies of reactants and products similar to the way in which you calculate the standard enthalpy of reaction from standard enthalpies of formation.

$$\Delta S^\circ = \sum n\Delta S^\circ(\text{products}) - \sum m\Delta S^\circ(\text{reactants})$$

##### Solution Essentials:

- Standard entropy,  $S^\circ$
- Entropy,  $S$

Calculate the change of entropy,  $\Delta S^\circ$ , at  $25^\circ\text{C}$  for the reaction in which urea is formed from  $\text{NH}_3$  and  $\text{CO}_2$ .

The standard entropy of  $\text{NH}_2\text{CONH}_2(aq)$  is  $174 \text{ J}/(\text{mol}\cdot\text{K})$ . See Table 18.1 for other values.

**Problem Strategy** The calculation is similar to that used to obtain  $\Delta H^\circ$  from  $\Delta H_f^\circ$  values.

**Solution** It is convenient to put the standard entropy values multiplied by stoichiometric coefficients below the formulas in the balanced equation.

You calculate the entropy change by subtracting the entropy of the reactants from the entropy of the products.

$$\begin{aligned} \Delta S^\circ &= \sum nS^\circ(\text{products}) - \sum mS^\circ(\text{reactants}) \\ &= [(174 + 70) - (2 \times 193 + 214)] \text{ J/K} = -356 \text{ J/K} \end{aligned}$$

**Answer Check** Carefully review your arithmetic. Also, note that moles of gas decrease, so we expect that the entropy decreases (and, thus, the sign should be negative; see Example 18.2b).

**Exercise 18.3** Calculate the change of entropy,  $\Delta S^\circ$ , for the reaction given in Example 18.2a. The standard entropy of glucose,  $\text{C}_6\text{H}_{12}\text{O}_6(s)$ , is  $212 \text{ J}/(\text{mol}\cdot\text{K})$ . See Table 18.1 for other values.

See Problems 18.41 and 18.42.

## ► Free-Energy Concept

At the end of Section 18.2, you saw that the quantity  $\Delta H - T\Delta S$  can serve as a criterion for spontaneity of a reaction at constant temperature and pressure. If the value of this quantity is negative, the reaction is spontaneous. If it is positive, the reaction is nonspontaneous. If it equals zero, the reaction is at equilibrium.

As an application of this criterion, consider the reaction described in the chapter opening, in which urea is prepared from  $\text{NH}_3$  and  $\text{CO}_2$ . The heat of reaction  $\Delta H^\circ$  was calculated from enthalpies of formation in Section 18.1, where we obtained  $-119.7 \text{ kJ}$ . Then, in Example 18.3, we calculated the entropy of reaction  $\Delta S^\circ$  and found a value of  $-356 \text{ J/K}$ , or  $-0.356 \text{ kJ/K}$ . Substitute these values and  $T = 298 \text{ K}$  ( $25^\circ\text{C}$ ) into the expression  $\Delta H^\circ - T\Delta S^\circ$ .

$$\Delta H^\circ - T\Delta S^\circ = (-119.7 \text{ kJ}) - (298 \text{ K})(-0.356 \text{ kJ/K}) = -13.6 \text{ kJ}$$

We see that  $\Delta H^\circ - T\Delta S^\circ$  is a negative quantity, from which we conclude that the reaction is spontaneous under standard conditions.

## 18.4 Free Energy and Spontaneity

It is very convenient to define a new thermodynamic quantity in terms of  $H$  and  $S$  that will be directly useful as a criterion of spontaneity. For this purpose, the American physicist J. Willard Gibbs (1839–1903) introduced the concept of **free energy**,  $G$ , which is *a thermodynamic quantity defined by the equation  $G = H - TS$* . This quantity gives a direct criterion for spontaneity of reaction. ►

As a reaction proceeds at a given temperature and pressure, reactants form products and the enthalpy  $H$  and entropy  $S$  change. These changes in  $H$  and  $S$ , denoted  $\Delta H$  and  $\Delta S$ , result in a change in free energy,  $\Delta G$ , given by the equation

$$\Delta G = \Delta H - T\Delta S$$

Note that the change in free energy,  $\Delta G$ , equals the quantity  $\Delta H - T\Delta S$  that you just saw serves as a criterion for spontaneity of a reaction. Thus, if you can show that  $\Delta G$  for a reaction at a given temperature and pressure is negative, you can predict that the reaction will be spontaneous.

### Standard Free-Energy Change

Recall that for purposes of tabulating thermodynamic data, certain *standard states* are chosen, which are indicated by a superscript degree sign on the symbol of the quantity.

**The standard states are as follows:** For pure liquids and solids, 1 atm pressure; for gases, 1 atm partial pressure; for solutions, 1  $M$  concentration. The temperature is the temperature of interest, usually 25°C (298 K).

The standard free-energy change,  $\Delta G^\circ$ , is the free-energy change that occurs when reactants in their standard states are converted to products in their standard states. Example 18.4 illustrates the calculation of the standard free-energy change,  $\Delta G^\circ$ , from  $\Delta H^\circ$  and  $\Delta S^\circ$ .

$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$$

The quantity  $G$  is called Gibbs energy, Gibbs free energy, or the Gibbs function—hence the symbol  $G$ .

### Example 18.4 Calculating $\Delta G^\circ$ from $\Delta H^\circ$ and $\Delta S^\circ$

#### Gaining Mastery Toolbox

##### Critical Concept 18.4

The standard free-energy change for a physical or chemical change equals the standard enthalpy change minus the absolute temperature times the standard entropy change,  $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$ .

##### Solution Essentials:

- Standard free-energy change,  $\Delta G^\circ$
- Free-energy change,  $\Delta G$
- Standard entropy change,  $\Delta S^\circ$
- Standard enthalpy of formation,  $\Delta H_f^\circ$

What is the standard free-energy change,  $\Delta G^\circ$ , for the following reaction at 25°C?

Use values of  $\Delta H_f^\circ$  and  $S^\circ$  from Tables 6.2 and 18.1.

**Problem Strategy** Calculate  $\Delta H^\circ$  and  $\Delta S^\circ$ , then substitute these values into  $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$  to obtain  $\Delta G^\circ$ .

**Solution** Write the balanced equation and place below each formula the values of  $\Delta H_f^\circ$  and  $S^\circ$  multiplied by stoichiometric coefficients.

You calculate  $\Delta H^\circ$  and  $\Delta S^\circ$  by taking values for products and subtracting values for reactants.

$$\begin{aligned} \Delta H^\circ &= \sum n\Delta H_f^\circ(\text{products}) - \sum m\Delta H_f^\circ(\text{reactants}) \\ &= [2 \times (-45.9) - 0] \text{ kJ} = -91.8 \text{ kJ} \end{aligned}$$

$$\begin{aligned} \Delta S^\circ &= \sum nS^\circ(\text{products}) - \sum mS^\circ(\text{reactants}) \\ &= [2 \times 192.7 - (191.6 + 3 \times 130.6)] \text{ J/K} = -198.0 \text{ J/K} \end{aligned}$$

(continued)

**Example 18.4** (continued)

You now substitute into the equation for  $\Delta G^\circ$  in terms of  $\Delta H^\circ$  and  $\Delta S^\circ$ . Note that you substitute  $\Delta S^\circ$  in units of kJ/K.

$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = -91.8 \text{ kJ} - (298 \text{ K})(-0.1980 \text{ kJ/K}) = \mathbf{-32.8 \text{ kJ}}$$

**Answer Check** Check your arithmetic. You need to be careful about the signs, especially when calculating  $\Delta H$ . Individual enthalpies of formation may be positive or negative. Also, you will be subtracting reactant data from product data.

**Exercise 18.4** Calculate  $\Delta G^\circ$  for the following reaction at 25°C. Use data given in Tables 6.2 and 18.1.

See Problems 18.45 and 18.46.

**Standard Free Energies of Formation**

The **standard free energy of formation**,  $\Delta G_f^\circ$ , of a substance is defined similarly to the standard enthalpy of formation. That is,  $\Delta G_f^\circ$  is *the free-energy change that occurs when 1 mol of substance is formed from its elements in their reference forms (usually the stablest states) at 1 atm and at a specified temperature (usually 25°C)*. (For a species in solution, the standard state is the 1 M solution.) For example, the standard free energy of formation of  $\text{NH}_3(g)$  is the free-energy change for the reaction

The reactants,  $\text{N}_2$  and  $\text{H}_2$ , each at 1 atm, are converted to the product,  $\text{NH}_3$ , at 1 atm pressure. In Example 18.4, you found  $\Delta G^\circ$  for the formation of 2 mol  $\text{NH}_3$  from its elements to be  $-32.8 \text{ kJ}$ . Hence,  $\Delta G_f^\circ(\text{NH}_3) = -32.8 \text{ kJ}/2 \text{ mol} = -16.4 \text{ kJ/mol}$ .

As in the case of standard enthalpies of formation, the standard free energies of formation of elements in their stablest states are assigned the value zero. By tabulating  $\Delta G_f^\circ$  for substances, as in Table 18.2, you can easily calculate  $\Delta G^\circ$  for any reaction involving those substances. You simply subtract the standard free energies of reactants from the standard free energies of products:

$$\Delta G^\circ = \sum n\Delta G_f^\circ(\text{products}) - \sum m\Delta G_f^\circ(\text{reactants})$$

The next example illustrates the calculations.

**Example 18.5** Calculating  $\Delta G^\circ$  from Standard Free Energies of Formation**Gaining Mastery Toolbox****Critical Concept 18.5**

You calculate the standard free-energy change for a physical or chemical change from the standard free energies of formation of reactants and products similar to the way in which you calculate the standard enthalpy of reaction from standard enthalpies of formation.

$$\Delta G^\circ = \sum n\Delta G_f^\circ(\text{products}) - \sum m\Delta G_f^\circ(\text{reactants})$$

**Solution Essentials:**

- Standard free-energy of formation,  $\Delta G_f^\circ$
- Standard free-energy change,  $\Delta G^\circ$
- Free-energy change,  $\Delta G$

Calculate  $\Delta G^\circ$  for the combustion of 1 mol of ethanol,  $\text{C}_2\text{H}_5\text{OH}$ , at 25°C.

Use the standard free energies of formation given in Table 18.2.

**Problem Strategy** Calculate  $\Delta G^\circ$  from  $\Delta G_f^\circ$  values, similar to the way you calculate  $\Delta H^\circ$  from  $\Delta H_f^\circ$ .

**Solution** Write the balanced equation with values of  $\Delta G_f^\circ$  multiplied by stoichiometric coefficients below each formula.

(continued)

**Table 18.2** Standard Free Energies of Formation (at 25°C)\*

Substance or Ion	$\Delta G_f^\circ$ (kJ/mol)	Substance or Ion	$\Delta G_f^\circ$ (kJ/mol)	Substance or Ion	$\Delta G_f^\circ$ (kJ/mol)

**Example 18.5** (continued)

The calculation is

$$\begin{aligned}\Delta G^\circ &= \sum n\Delta G_f^\circ(\text{products}) - \sum m\Delta G_f^\circ(\text{reactants}) \\ &= [2(-394.4) + 3(-228.6) - (-174.9)] \text{ kJ} \\ &= -1299.7 \text{ kJ}\end{aligned}$$

**Answer Check** As in calculating  $\Delta H$  values, you need to be careful of signs. Also, note that you can obtain standard free energies from Appendix C. Just be careful to use the correct column for  $\Delta G^\circ$  values.

**Exercise 18.5** Calculate  $\Delta G^\circ$  at 25°C for the following reaction, using values of  $\Delta G_f^\circ$ .

See Problems 18.49 and 18.50.

 **$\Delta G^\circ$  as a Criterion for Spontaneity**

You have already seen that the quantity  $\Delta G = \Delta H - T\Delta S$  can be used as a criterion for the spontaneity of a reaction. The change of free energy,  $\Delta G$ , should be calculated for the conditions at which the reaction occurs. If the reactants are at standard conditions and give products at standard conditions, the free-energy change you need to look at is  $\Delta G^\circ$ . The calculation is simple, as shown in Example 18.5. For other conditions, you should look at the appropriate  $\Delta G$  value. This would be a more complicated calculation. Nevertheless, the standard free-energy change  $\Delta G^\circ$  is still a useful guide to the spontaneity of reaction in these cases. The following rules are useful in judging the spontaneity of a reaction:

1. When  $\Delta G^\circ$  is a large negative number (more negative than about  $-10$  kJ), the reaction is spontaneous as written, and reactants transform almost entirely to products when equilibrium is reached.
2. When  $\Delta G^\circ$  is a large positive number (larger than about 10 kJ), the reaction is nonspontaneous as written, and reactants do not give significant amounts of products at equilibrium.
3. When  $\Delta G^\circ$  has a small negative or positive value (less than about 10 kJ), the reaction gives an equilibrium mixture with significant amounts of both reactants and products.

**Example 18.6** Interpreting the Sign of  $\Delta G^\circ$ **Gaining Mastery Toolbox****Critical Concept 18.6**

A reaction is spontaneous when  $\Delta G^\circ$  is negative; otherwise, the reaction is nonspontaneous. However, when the standard free-energy change is near zero (from about  $-10$  kJ to 10 kJ), the reaction gives an equilibrium mixture with significant amounts of reactants and products.

**Solution Essentials:**

- Standard free-energy of formation,  $\Delta G_f^\circ$
- Standard free-energy change,  $\Delta G^\circ$
- Standard enthalpy of formation,  $\Delta H_f^\circ$
- Standard enthalpy of reaction,  $\Delta H^\circ$

Calculate  $\Delta H^\circ$  and  $\Delta G^\circ$  for the reaction

Interpret the signs obtained for  $\Delta H^\circ$  and  $\Delta G^\circ$ . Values of  $\Delta H_f^\circ$  (in kJ/mol) are as follows:  $\text{KClO}_3(s)$ ,  $-397.7$ ;  $\text{KCl}(s)$ ,  $-436.7$ . Similarly, values of  $\Delta G_f^\circ$  (in kJ/mol) are as follows:  $\text{KClO}_3(s)$ ,  $-296.3$ ;  $\text{KCl}(s)$ ,  $-408.8$ . Note that  $\text{O}_2(g)$  is the reference form of the element, so  $\Delta H_f^\circ = \Delta G_f^\circ = 0$  for it.

**Problem Strategy** Calculate  $\Delta H^\circ$  and  $\Delta G^\circ$ ; then interpret the signs of these quantities. The interpretation of the sign of  $\Delta H$  was discussed in Chapter 6. As long as  $\Delta G^\circ$  is not close to zero, you can interpret its sign as follows: a negative  $\Delta G^\circ$  means the reactants tend to go mostly to products; a positive  $\Delta G^\circ$  means that the reaction is nonspontaneous as written. When the value of  $\Delta G^\circ$  is close to zero, the reaction gives an equilibrium mixture.

(continued)

**Example 18.6** (continued)**Solution** The problem is set up as follows:

Then,

$$\Delta H^\circ = [2 \times (-436.7) - 2 \times (-397.7)] \text{ kJ} = -78.0 \text{ kJ}$$

$$\Delta G^\circ = [2 \times (-408.8) - 2 \times (-296.3)] \text{ kJ} = -225.0 \text{ kJ}$$

The reaction is exothermic, liberating 78.0 kJ of heat. The large negative value for  $\Delta G^\circ$  indicates that the equilibrium composition is mostly potassium chloride and oxygen.

**Answer Check** Check your arithmetic. Then remember that a negative sign for  $\Delta H^\circ$  means that heat was lost from the system; a large negative sign for  $\Delta G^\circ$  means that products predominate.

**Exercise 18.6** Which of the following reactions are spontaneous in the direction written? See Table 18.2 for data.

See Problems 18.53 and 18.54.

- $\text{C}(\text{graphite}) + 2\text{H}_2(g) \longrightarrow \text{CH}_4(g)$
- $2\text{H}_2(g) + \text{O}_2(g) \longrightarrow 2\text{H}_2\text{O}(l)$
- $4\text{HCN}(g) + 5\text{O}_2(g) \longrightarrow 2\text{H}_2\text{O}(l) + 4\text{CO}_2(g) + 2\text{N}_2(g)$
- $\text{Ag}^+(aq) + \text{I}^-(aq) \longrightarrow \text{AgI}(s)$

**CONCEPT CHECK 18.2**

Consider the reaction of nitrogen,  $\text{N}_2$ , and oxygen,  $\text{O}_2$ , to form nitrogen monoxide,  $\text{NO}$ :

From the standard free energy of formation of  $\text{NO}$ , what can you say about this reaction?

**18.5 Interpretation of Free Energy**

You have seen that the free-energy change serves as a criterion for spontaneity of a chemical reaction. This gives you some idea of what free energy is and how you interpret it. In this section, we will look more closely at the meaning of free energy.

**Maximum Work**

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCH 02-200-203

Theoretically, spontaneous reactions can be used to obtain useful work. By useful work, we mean energy that can be used directly to move objects of normal size. We use the combustion of gasoline to move an automobile, and we use a reaction in a battery to generate electricity to drive a motor. Similarly, biochemical reactions in muscle tissue occur in such a way as to contract muscle fibers and lift a weight.

Often reactions are not carried out in a way that does useful work. The reactants are simply poured together in a reaction vessel, and products are separated from the mixture. As the reaction occurs, the free energy of the system decreases and entropy is produced, but no useful work is obtained.

In principle, if a reaction is carried out to obtain the maximum useful work, no entropy is produced. It can be shown that the maximum useful work,  $w_{max}$ , for a spontaneous reaction is  $\Delta G$ .

$$w_{max} = \Delta G$$

## Life Science

A CHEMIST Looks at . . .

## Coupling of Reactions

Many important processes are thermodynamically unfavorable, or *nonspontaneous*. Assembling many small amino acid molecules into a large protein molecule is an example of a nonspontaneous process. Yet biological organisms do assemble proteins from amino acids. Biological organisms accomplish many similar nonspontaneous processes. How do they do this?

Let's look at a simpler example. We would like to obtain iron metal from iron ore. Here is the equation for the direct decomposition of iron(III) oxide, the iron-containing substance in the iron ore hematite:

This reaction is clearly nonspontaneous, because  $\Delta G^\circ$  is a large positive quantity. The nonspontaneity of this reaction is in agreement with common knowledge. Iron tends to rust (forms iron oxide) in air, by combining with oxygen. You do not expect a rusty wrench to turn spontaneously into shiny iron and oxygen. But this does not mean you cannot change iron(III) oxide to iron metal. It merely means that you have to do work on the iron(III) oxide to reduce it to the metal. You must, in effect, find a way to couple this nonspontaneous reaction to one that is sufficiently spontaneous; that is, you must couple this reaction to one having a more negative  $\Delta G^\circ$ .

Consider the spontaneous reaction of carbon monoxide with oxygen (the burning of CO):

For 3 mol  $\text{O}_2$ ,  $\Delta G^\circ$  is  $-1543 \text{ kJ}$ , which is more negative than for the direct decomposition of 2 mol  $\text{Fe}_2\text{O}_3$  to its elements. Let us add the two reactions:

The net result is to reduce iron(III) oxide to the metal by reacting the oxide with carbon monoxide. This is the reaction that occurs in a blast furnace, where iron ore is commercially reduced to iron.

The concept of the coupling of two chemical reactions, a nonspontaneous reaction with a spontaneous one, to give an overall spontaneous change is a very useful one, especially in biochemistry. Adenosine triphosphate, or ATP, is a molecule containing a triphosphate group. It reacts with water, in the presence of an enzyme (biochemical catalyst), to give adenosine diphosphate, ADP, and a phosphate ion. (Figure 18.7 shows the structure of ATP and ADP.) The reaction has a negative  $\Delta G^\circ$  (and is a spontaneous reaction).

ATP is first synthesized in a living organism; the energy for this synthesis is obtained from food. The spontaneous reaction of ATP with water to give ADP and phosphate ion is then coupled to various nonspontaneous reactions in the organism to accomplish necessary life processes (see Figure 18. 8).

(continued)

The sign of  $w$  (work) is defined so that a negative value means work is obtained from the system (that is, energy is subtracted from the system). You can obtain work from a reaction if its  $\Delta G$  is negative.

The term *free energy* comes from this result. *The free-energy change is the maximum energy available, or free, to do useful work.* As a reaction occurs in such a way as to give the maximum useful work, the free energy decreases and a corresponding quantity of useful work is obtained. ◀

The concept of maximum work from a chemical reaction is an idealization. In any real situation, less than this maximum work is obtained and some entropy is created. When this work is eventually expended, it appears in the environment as additional entropy.

## Free-Energy Change During Reaction

You have seen that the free-energy change is related to the work done during a chemical reaction. Consider the combustion of gasoline in  $\text{O}_2$ . The reaction is

## A CHEMIST Looks at . . . Coupling of Reactions *(continued)*

**Figure 18.7** ▲

**Molecular models of ATP and ADP** The phosphate groups are on the left, with the phosphorus atoms shown in orange, oxygen atoms in red, nitrogen atoms in blue, carbon atoms in gray, and hydrogen atoms in light blue.

**Figure 18.8** ►

**Coupling of reactions in a biological cell** The mitochondria are parts of a cell that obtain energy in the form of ATP from glucose (from food),  $C_6H_{12}O_6$ . ATP molecules are used in various cell processes, such as protein synthesis from amino acids, which occurs in the ribosomes.

■ See Problems 18.101 and 18.102.

spontaneous, so the free-energy change is negative. That is, the free energy of the system changes to a lower value as the reactants are converted to products. Figure 18.9 shows the free-energy change that occurs during this reaction. When the gasoline is burned in a gasoline stove, the decrease in free energy shows up as an increase in entropy of the system and the surroundings. However, when the gasoline is burned in an automobile engine, some of the decrease in free energy shows up as work done. Theoretically, all of the free-energy decrease can be used to do work. This gives the maximum work. In practice, less work is obtained, and the difference appears as an increase of entropy. Ultimately, the work is itself used up—that is, changed to entropy. ►

Look at Figure 18.9 again. At the start of the reaction, the system contains only reactants: gasoline and  $O_2$ . The free energy has a relatively high value. This decreases as the reaction proceeds. The decrease in free energy appears either

What happens in the gasoline engine is complicated, but you need look at only the initial and final states. Reactants at the surrounding temperature and pressure go into the engine, which produces work and heat, and the products leave the engine, eventually reaching the initial temperature and pressure of the reactants.

**Figure 18.9** ▲

**Free-energy change during a spontaneous reaction (combustion of gasoline)** The free energy decreases as the reaction proceeds. At equilibrium, the free energy becomes a minimum, and the equilibrium mixture is mostly products.

**Figure 18.10** ▲

**Free-energy change during a nonspontaneous reaction** The free energy decreases until equilibrium, at which the minimum value is reached. There is very little reaction, however, because the equilibrium mixture is mostly reactants. To change reactants to mostly products is to undergo a nonspontaneous reaction.

as an increase in entropy or as work done. Eventually, the free energy of the system reaches its minimum value. Then the net reaction stops; it comes to equilibrium.

Before we leave this section, consider a reaction in which  $\Delta G^\circ$  is positive. You would predict that the reaction is nonspontaneous. Figure 18.10 shows the free-energy change as the reaction proceeds. Note that there is a small decrease in free energy as the system goes to equilibrium. Some reaction occurs in order to give the equilibrium mixture. But this mixture consists primarily of reactants, because the reaction does not go very far before coming to equilibrium. To change reactants completely to products is a nonspontaneous reaction (shown by the arrow along the curve in Figure 18.10).

## ► Free Energy and Equilibrium Constants

In the previous section, you saw that for any spontaneous reaction, the total free energy of the substances in the reaction mixture decreases as the reaction proceeds (that is, the free-energy change is negative). Earlier, you saw that the standard free-energy change,  $\Delta G^\circ$ , can be used as a criterion for the spontaneity of a reaction. When  $\Delta G^\circ$  is negative, the reaction is spontaneous. We will now describe how the standard free-energy change is related to the equilibrium constant.

### 18.6 Relating $\Delta G^\circ$ to the Equilibrium Constant

One of the most important results of chemical thermodynamics is an equation relating the standard free-energy change for a reaction to the equilibrium constant. Before we look at this equation, we must discuss the thermodynamic form of the equilibrium constant that occurs in that equation.

The **thermodynamic equilibrium constant,  $K$** , is *the equilibrium constant in which the concentrations of gases are expressed in partial pressures in atmospheres, whereas the concentrations of solutes in liquid solutions are expressed in molarities*. For a reaction involving only solutes in liquid solution,  $K$  is identical to  $K_c$ ; for reactions involving only gases,  $K$  equals  $K_p$ . ◀

To be precise,  $K$  is defined in terms of activities, which are dimensionless quantities numerically equal to "effective" concentrations and pressures.

**Example 18.7 Writing the Expression for a Thermodynamic Equilibrium Constant****Gaining Mastery Toolbox****Critical Concept 18.7**

You write the expression for the thermodynamic equilibrium constant with gases expressed as partial pressures and concentrations of solutes as molarities.

**Solution Essentials:**

- Equilibrium-constant expression for gases  $K_p$
- Equilibrium-constant expression  $K_c$

Write expressions for the thermodynamic equilibrium constants for each of the following reactions:

- a. The reaction given in the chapter opening,

- b. The solubility process

**Problem Strategy** The thermodynamic equilibrium constant,  $K$ , has characteristics of  $K_p$  and  $K_c$ . All gases appear in  $K$  as partial pressures; all solutes appear as concentrations. Pure solids and liquids do not appear in the equilibrium constant.

**Solution**

- a. Note that  $\text{H}_2\text{O}$  is a solvent, so it does not appear explicitly in  $K$ . The gases appear in  $K$  as partial pressures, and the solute appears as a molar concentration.

$$K = \frac{[\text{NH}_2\text{CONH}_2]}{P_{\text{NH}_3}^2 P_{\text{CO}_2}}$$

- b. Note that  $\text{AgCl}$  is a solid, so it does not appear explicitly in  $K$ . The solutes appear as molar concentrations.

$$K = [\text{Ag}^+][\text{Cl}^-]$$

This is identical to  $K_{sp}$ .

**Answer Check** Make sure that the products are on top and the reactants are on the bottom of each equilibrium-constant expression. Then check that each reactant and product term is raised to the correct power (equal to the stoichiometric coefficient in the chemical equation).

**Exercise 18.7** Give the expression for  $K$  for each of the following reactions.

See Problems 18.59 and 18.60.

The standard free-energy change,  $\Delta G^\circ$ , for a reaction can be calculated using data from thermodynamic tables. If you want the free-energy change when reactants under nonstandard conditions are changed to products under nonstandard conditions ( $\Delta G$ ), you can obtain it from the standard free-energy change  $\Delta G^\circ$  using the following equation:

$$\Delta G = \Delta G^\circ + RT \ln Q$$

Here  $Q$  is the thermodynamic form of the reaction quotient. It has the same general appearance as the thermodynamic equilibrium constant  $K$ , but the concentrations and partial pressures are those for a mixture at some instant, perhaps at the beginning of a reaction. You obtain  $\Delta G$  from  $\Delta G^\circ$  by adding  $RT \ln Q$ , where  $\ln Q$  is the natural logarithm of  $Q$  ( $\ln Q = 2.303 \log Q$ ). Note that  $\Delta G$  is the change of free energy that occurs when the reaction mixture has the composition expressed by  $Q$ . ▶

You can derive the equation relating  $\Delta G^\circ$  to the equilibrium constant  $K$  from the preceding equation. In the previous section, you saw that as a chemical reaction approaches equilibrium, the free energy decreases and continues to decrease until equilibrium is reached. At equilibrium, the free energy ceases to change; then  $\Delta G = 0$ . Also, the reaction quotient  $Q$  becomes equal to the

Strictly speaking, because the composition changes with reaction,  $\Delta G$  is for an infinitesimal change in  $G$  per infinitesimal change in reaction amounts; that is,  $\Delta G$  equals the slope of the reaction curve (like the curves in Figures 18.9 and 18.10).

equilibrium constant  $K$ . If you substitute  $\Delta G = 0$  and  $Q = K$  into the preceding equation, you obtain

$$0 = \Delta G^\circ + RT \ln K$$

This result is easily rearranged to give the basic equation relating the standard free-energy change to the equilibrium constant.

$$\Delta G^\circ = -RT \ln K$$

The next example illustrates the calculation of a thermodynamic equilibrium constant from the standard free-energy change,  $\Delta G^\circ$ .

### Example 18.8 Calculating $K$ from the Standard Free-Energy Change (Molecular Equation)

#### Gaining Mastery Toolbox

##### Critical Concept 18.8

The standard free-energy change and the thermodynamic equilibrium constant for a reaction at a given temperature are related:  $\Delta G^\circ = -RT \ln K$ .

##### Solution Essentials:

- Thermodynamic equilibrium constant,  $K$
- Standard free-energy change,  $\Delta G^\circ$

Find the value of the equilibrium constant  $K$  at 25°C (298 K) for the reaction

The standard free-energy change,  $\Delta G^\circ$ , at 25°C equals  $-13.6$  kJ. (We calculated this value of  $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$  just before Section 18.4.)

**Problem Strategy** Rearrange the equation  $\Delta G^\circ = -RT \ln K$  to give

$$\ln K = \frac{\Delta G^\circ}{-RT}$$

$\Delta G^\circ$  and  $R$  must be in compatible units. You normally express  $\Delta G^\circ$  in joules and set  $R$  equal to  $8.31$  J/(K·mol).

**Solution** Substituting numerical values into this equation,

$$\ln K = \frac{-13.6 \times 10^3}{-8.31 \times 298} = 5.49$$

Hence,

$$K = e^{5.49} = 2.4 \times 10^2$$

Note that although the value of  $K$  indicates that products predominate at equilibrium,  $K$  is only moderately large. You would expect that the composition could be easily shifted toward reactants if you could remove either  $\text{NH}_3$  or  $\text{CO}_2$  (according to Le Châtelier's principle). This is what happens when urea is used as a fertilizer. As  $\text{NH}_3$  is used up, more  $\text{NH}_3$  is produced by the decomposition of urea.

**Answer Check** Make sure that you have expressed  $\Delta G^\circ$  and  $R$  in similar units. If  $\Delta G^\circ$  is given in kJ/mol, whereas  $R$  is given in J/(K·mol), express both in joules or both in kilojoules. (If you always carry units in your calculations, you will not make a mistake in units.) Also, note that  $\ln$  is the natural logarithm, and its inverse or antilogarithm is the exponential function. Thus, the inverse of  $\ln x$  is  $e^x$ .

**Exercise 18.8** Use the data from Table 18.2 to obtain the equilibrium constant  $K_p$  at 25°C for the reaction

Note that values of  $\Delta G_f^\circ$  are needed for  $\text{CaCO}_3$  and  $\text{CaO}$ , even though the substances do not appear in  $K_p = P_{\text{CO}_2}$ .

See Problems 18.61, 18.62, 18.63, and 18.64.

The method of calculating  $K$  from  $\Delta G^\circ$  also works for net ionic equations. In Example 18.9, you obtain a solubility product constant from thermodynamic data.

**Example 18.9 Calculating  $K$  from the Standard Free-Energy Change (Net Ionic Equation)****Gaining Mastery Toolbox****Critical Concept 18.9**

The standard free-energy change and the thermodynamic equilibrium constant for a reaction at a given temperature are related:  $\Delta G^\circ = -RT \ln K$ .

**Solution Essentials:**

- Thermodynamic equilibrium constant,  $K$
- Standard free-energy change,  $\Delta G^\circ$

Calculate the equilibrium constant  $K_{sp}$  at 25°C for the reaction

using standard free energies of formation.

**Problem Strategy** This is similar to the preceding example, except that you must first calculate  $\Delta G_f^\circ$  for the ionic equation. Note that  $K_{sp}$  equals  $K$ , the thermodynamic equilibrium constant.

**Solution** You first calculate  $\Delta G^\circ$ . Writing  $\Delta G_f^\circ$  values below the formulas in the equation gives

Hence,

$$\begin{aligned} \Delta G^\circ &= [(77.1 - 131.3) - (-109.8)] \text{ kJ} \\ &= 55.6 \text{ kJ (or } 55.6 \times 10^3 \text{ J)} \end{aligned}$$

You now substitute numerical values into the equation relating  $\ln K$  and  $\Delta G^\circ$ .

$$\ln K = \frac{\Delta G^\circ}{-RT} = \frac{55.6 \times 10^3}{-8.31 \times 298} = -22.45$$

Therefore,

$$K = e^{-22.45} = \mathbf{1.8 \times 10^{-10}}$$

**Answer Check** When you calculate  $\Delta G^\circ$ , be careful of signs. In this example, note that the last term in calculating  $\Delta G^\circ$  has a minus sign before  $-109.8$ , which gives  $+109.8$ .

**Exercise 18.9** Calculate the solubility product constant for  $\text{Mg}(\text{OH})_2$  at 25°C. The  $\Delta G_f^\circ$  values (in kJ/mol) are as follows:  $\text{Mg}^{2+}(aq)$ ,  $-454.8$ ;  $\text{OH}^-(aq)$ ,  $-157.3$ ;  $\text{Mg}(\text{OH})_2(s)$ ,  $-833.7$ .

See Problems 18.65 and 18.66.

You can understand the use of  $\Delta G^\circ$  as a criterion for spontaneity by looking at its relationship to the equilibrium constant,  $\Delta G^\circ = -RT \ln K$ . When the equilibrium constant is greater than 1,  $\ln K$  is positive and  $\Delta G^\circ$  is negative. Similarly, when the equilibrium constant is less than 1,  $\ln K$  is negative and  $\Delta G^\circ$  is positive. This agrees with the first two rules listed at the end of Section 18.4. You can get the third rule by substituting  $\Delta G^\circ = \pm 10 \times 10^3 \text{ J}$  into  $\Delta G^\circ = -RT \ln K$  and solving for  $K$ . You find that  $K$  is between 0.018 and 57. In this range, the equilibrium mixture contains significant amounts of reactants as well as products.

 **CONCEPT CHECK 18.3**

The following reaction is spontaneous in the direction given.

Suppose you are given a vessel containing an equilibrium mixture of A, B, C, and D, and you increase the concentration of C by increasing its partial pressure.

- How is the standard free-energy change,  $\Delta G^\circ$ , affected by the addition of C to the vessel?
- How is the free-energy change,  $\Delta G$ , affected by the addition of C to the vessel?

**Table 18.3** Effect of Temperature on the Spontaneity of Reactions

$\Delta H^\circ$	$\Delta S^\circ$	$\Delta G^\circ$	Description*	Example
–	+	–	Spontaneous at all $T$	$\text{C}_6\text{H}_{12}\text{O}_6(s) \longrightarrow 2\text{C}_2\text{H}_5\text{OH}(l) + 2\text{CO}_2(g)$
+	–	+	Nonspontaneous at all $T$	$3\text{O}_2(g) \longrightarrow 2\text{O}_3(g)$
–	–	+ or –	Spontaneous at low $T$ ; nonspontaneous at high $T$	$2\text{NH}_3(g) + \text{CO}_2(g) \longrightarrow \text{NH}_2\text{CONH}_2(aq) + \text{H}_2\text{O}(l)$
+	+	+ or –	Nonspontaneous at low $T$ ; spontaneous at high $T$	$\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}(s) + 2\text{NH}_4\text{NO}_3(s) \longrightarrow \text{Ba}(\text{NO}_3)_2(aq) + 2\text{NH}_3(g) + 10\text{H}_2\text{O}(l)$

\*The terms *low temperature* and *high temperature* are relative. For a particular reaction, *high temperature* could mean room temperature.

of the terms  $\Delta H^\circ$  and  $-T\Delta S^\circ$ . The reaction is spontaneous at room temperature but would be nonspontaneous at a sufficiently low temperature. Table 18.3 summarizes this discussion.

#### CONCEPT CHECK 18.4

Consider the decomposition of dinitrogen tetroxide,  $\text{N}_2\text{O}_4$ , to nitrogen dioxide,  $\text{NO}_2$ :

How would you expect the spontaneity of the reaction to behave with temperature change?

### Calculation of $\Delta G^\circ$ at Various Temperatures

As an application of the method of calculating  $\Delta G^\circ$  at various temperatures, assuming  $\Delta H^\circ$  and  $\Delta S^\circ$  are constant, look at the following reaction:

At  $25^\circ\text{C}$ ,  $\Delta G^\circ$  equals  $+130.9$  kJ, and the equilibrium partial pressure of  $\text{CO}_2$  calculated from this is  $1.1 \times 10^{-23}$  atm. The very small value of this partial pressure shows

### Example 18.10 Calculating $\Delta G^\circ$ and $K$ at Various Temperatures

#### Gaining Mastery Toolbox

##### Critical Concept 18.10

You can estimate the free-energy change for a reaction at a temperature  $T$  from the standard enthalpy and standard entropy changes at  $25^\circ\text{C}$ :  
 $\Delta G_T^\circ = \Delta H^\circ - T\Delta S^\circ$ .

##### Solution Essentials:

- Relation between standard free-energy change and equilibrium constant,  $\Delta G^\circ = -RT \ln K$
- Standard free-energy change,  $\Delta G^\circ$
- Free-energy change,  $\Delta G$
- Standard entropy change,  $\Delta S^\circ$
- Standard enthalpy of reaction,  $\Delta H^\circ$

a. What is  $\Delta G^\circ$  at  $1000^\circ\text{C}$  for the following reaction?

Is this reaction spontaneous at  $1000^\circ\text{C}$  and 1 atm?

b. What is the value of  $K_p$  at  $1000^\circ\text{C}$  for this reaction? What is the partial pressure of  $\text{CO}_2$ ?

#### Problem Strategy

- Calculate  $\Delta H^\circ$  and  $\Delta S^\circ$  at  $25^\circ\text{C}$  using standard enthalpies of formation and standard entropies. Then substitute into the equation for  $\Delta G_T^\circ$ .
- Use the value of  $\Delta G_T^\circ$  to find  $K$  ( $= K_p$ ), as in Example 18.8.

(continued)

**Example 18.10** (continued)**Solution**

a. From Tables 6.2 and 18.1, you have

You calculate  $\Delta H^\circ$  and  $\Delta S^\circ$  from these values.

$$\Delta H^\circ = [(-635.1 - 393.5) - (-1206.9)] \text{ kJ} = 178.3 \text{ kJ}$$

$$\Delta S^\circ = [(38.2 + 213.7) - (92.9)] \text{ J/K} = 159.0 \text{ J/K}$$

Now you substitute  $\Delta H^\circ$ ,  $\Delta S^\circ$  ( $= 0.1590 \text{ kJ/K}$ ), and  $T$  ( $= 1273 \text{ K}$ ) into the equation for  $\Delta G_T^\circ$ .

$$\Delta G_T^\circ = \Delta H^\circ - T\Delta S^\circ = 178.3 \text{ kJ} - (1273 \text{ K})(0.1590 \text{ kJ/K}) = \mathbf{-24.1 \text{ kJ}}$$

Because  $\Delta G_T^\circ$  is negative, the reaction should be **spontaneous** at  $1000^\circ\text{C}$  and 1 atm.

b. Substitute the value of  $\Delta G^\circ$  at 1273 K, which equals  $-24.1 \times 10^3 \text{ J}$ , into the equation relating  $\ln K$  and  $\Delta G^\circ$ .

$$\ln K = \frac{\Delta G^\circ}{-RT} = \frac{-24.1 \times 10^3}{-8.31 \times 1273} = 2.278$$

$$K = K_p = e^{2.278} = \mathbf{9.8}$$

$K_p = P_{\text{CO}_2}$ , so the partial pressure of  $\text{CO}_2$  is **9.8 atm**.

**Answer Check** The things to be careful of have been noted before: watch the signs in calculating  $\Delta H^\circ$  and  $\Delta S^\circ$ , and always use compatible units. Usually,  $\Delta H^\circ$  is given in kJ, whereas  $\Delta S^\circ$  is given in J/K. Here, we converted the units for  $\Delta S^\circ$  to kJ/K. As long as you carry units in your calculations, you will detect any error in choice of units that you might make.

**Exercise 18.10** The thermodynamic equilibrium constant for the vaporization of water,

is  $K_p = P_{\text{H}_2\text{O}}$ . Use thermodynamic data to calculate the vapor pressure of water at  $45^\circ\text{C}$ . Compare your answer with the value given in Appendix B.

See Problems 18.67 and 18.68.

that  $\text{CaCO}_3$  is quite stable at room temperature. In the next example, you will see how  $\Delta G^\circ$  and  $K_p$  for this reaction change at higher temperature.

You can use the ideas described in this section to find the temperature at which a reaction such as the decomposition of  $\text{CaCO}_3$  changes from nonspontaneous to spontaneous under standard conditions (1 atm for reactants and products). At this temperature,  $\Delta G^\circ$  equals zero.

$$\Delta G^\circ = 0 = \Delta H^\circ - T\Delta S^\circ$$

Solving for  $T$  gives

$$T = \frac{\Delta H^\circ}{\Delta S^\circ}$$

For the decomposition of  $\text{CaCO}_3$ , using values obtained in Example 18.10, you get

$$T = \frac{178.3 \text{ kJ}}{0.1590 \text{ kJ/K}} = 1121 \text{ K} (848^\circ\text{C})$$

Thus,  $\text{CaCO}_3$  should be stable to thermal decomposition to  $\text{CaO}$  and  $\text{CO}_2$  at 1 atm until heated to  $848^\circ\text{C}$ . This is only approximate, of course, because you assumed that  $\Delta H^\circ$  and  $\Delta S^\circ$  are constant with temperature.

	<p><b>Exercise 18.11</b> To what temperature must magnesium carbonate be heated to decompose it to <math>\text{MgO}</math> and <math>\text{CO}_2</math> at 1 atm? Is this higher or lower than the temperature required to decompose <math>\text{CaCO}_3</math>? Values of <math>\Delta H_f^\circ</math> (in <math>\text{kJ/mol}</math>) are as follows: <math>\text{MgO}(s)</math>, <math>-601.2</math>; <math>\text{MgCO}_3(s)</math>, <math>-1111.7</math>. Values of <math>S^\circ</math> (in <math>\text{J/K}</math>) are as follows: <math>\text{MgO}(s)</math>, <math>26.9</math>; <math>\text{MgCO}_3(s)</math>, <math>65.9</math>. Data for <math>\text{CO}_2</math> are given in Tables 6.2 and 18.1.</p>	See Problems 18.69 and 18.70.
--	---	-------------------------------

## A Checklist for Review

### Summary of Facts and Concepts

Entropy,  $S$ , is a thermodynamic measure of energy dispersal in a system. According to the *second law of thermodynamics*, the total entropy of a system and its surroundings increases for a *spontaneous process*, one that occurs of its own accord. For a spontaneous reaction at constant  $T$  and  $P$ , you can show that the entropy change  $\Delta S$  is greater than  $\Delta H/T$ . For an equilibrium process, such as a phase transition,  $\Delta S = \Delta H/T$ . The standard entropy  $S^\circ$  of a substance is determined by measuring the heat absorbed in warming it at increasing temperatures at 1 atm. The method depends on the *third law of thermodynamics*, which states that perfectly crystalline substances at 0 K have zero entropy.

Free energy,  $G$ , is defined as  $H - TS$ . The change in free energy,  $\Delta G$ , for a reaction at constant  $T$  and  $P$  equals  $\Delta H - T\Delta S$ , which is negative for a spontaneous change. Standard free-energy changes,  $\Delta G^\circ$ , can be calculated from  $\Delta H_f^\circ$  and  $S^\circ$  values or from standard free energies of formation,  $\Delta G_f^\circ$ .  $\Delta G_f^\circ$  for a substance is the standard free-energy change for the formation of the substance

from the elements in their stablest states. The standard free-energy change,  $\Delta G^\circ$ , serves as a *criterion for spontaneity* of a reaction. A negative value means the reaction is spontaneous. A value of zero means the reaction is at equilibrium. A positive value means the reaction is nonspontaneous.

The free-energy change,  $\Delta G$ , is related to the *maximum work* that can be done by a reaction. This maximum work equals  $\Delta G$ . A nonspontaneous reaction can be made to go by coupling it with a reaction that has a negative  $\Delta G$ , so that  $\Delta G$  for the overall result is negative. The reaction with the negative  $\Delta G$  does work on the nonspontaneous reaction.

The *thermodynamic equilibrium constant*,  $K$ , can be calculated from the standard free-energy change by the relationship  $\Delta G^\circ = -RT \ln K$ .  $\Delta G^\circ$  at various temperatures can be obtained by using the approximation that  $\Delta H^\circ$  and  $\Delta S^\circ$  are temperature independent. Therefore,  $\Delta G^\circ$ , which equals  $\Delta H^\circ - T\Delta S^\circ$ , can be easily calculated for any  $T$ .

### Learning Objectives

#### 18.1 First Law of Thermodynamics: A Review

- Recall the statement of the first law of thermodynamics.
- Recall the definition of enthalpy.
- Recall that the heat of reaction at constant pressure equals the enthalpy change.
- Recall how to calculate the enthalpy of reaction from standard enthalpies of formation.

### Important Terms

#### 18.2 Entropy and the Second Law of Thermodynamics

- Define *spontaneous process*.
- Define *entropy*.
- Relate entropy to disorder in a molecular system (energy dispersal).
- State the *second law of thermodynamics* in terms of system plus surroundings.
- State the second law of thermodynamics in terms of the system only.

**spontaneous process**  
**entropy,  $S$**   
**second law of thermodynamics**

- Calculate the entropy change for a phase transition. **Example 18.1**
- Describe how  $\Delta H - T\Delta S$  functions as a criterion of a spontaneous reaction.

### 18.3 Standard Entropies and the Third Law of Thermodynamics

- State the *third law of thermodynamics*.
- Define *standard entropy (absolute entropy)*.
- State the situations in which the entropy usually increases.
- Predict the sign of the entropy change of a reaction. **Example 18.2**
- Express the standard change of entropy of a reaction in terms of standard entropies of products and reactants.
- Calculate  $\Delta S^\circ$  for a reaction. **Example 18.3**

**third law of thermodynamics**  
**standard (absolute) entropy**

### 18.4 Free Energy and Spontaneity

- Define *free energy, G*.
- Define the *standard free-energy change*.
- Calculate  $\Delta G^\circ$  from  $\Delta H^\circ$  and  $\Delta S^\circ$ . **Example 18.4**
- Define the *standard free energy of formation,  $\Delta G_f^\circ$* .
- Calculate  $\Delta G^\circ$  from standard free energies of formation. **Example 18.5**
- State the rules for using  $\Delta G^\circ$  as a criterion for spontaneity.
- Interpret the sign of  $\Delta G^\circ$ . **Example 18.6**

**free energy, G**  
**standard free energy of formation,  $\Delta G_f^\circ$**

### 18.5 Interpretation of Free Energy

- Relate the free-energy change to maximum useful work.
- Describe how the free energy changes during a chemical reaction.

### 18.6 Relating $\Delta G^\circ$ to the Equilibrium Constant

- Define the *thermodynamic equilibrium constant, K*.
- Write the expression for a thermodynamic equilibrium constant. **Example 18.7**
- Indicate how the free-energy change of a reaction and the reaction quotient are related.
- Relate the standard free-energy change to the thermodynamic equilibrium constant.
- Calculate  $K$  from the standard free-energy change (molecular equation). **Example 18.8**
- Calculate  $K$  from the standard free-energy change (net ionic equation). **Example 18.9**

**thermodynamic equilibrium constant, K**

### 18.7 Change of Free Energy with Temperature

- Describe how  $\Delta G^\circ$  at a given temperature ( $\Delta G_T^\circ$ ) is approximately related to  $\Delta H^\circ$  and  $\Delta S^\circ$  at 25°C.
- Describe how the spontaneity or nonspontaneity of a reaction is related to each of the four possible combinations of signs of  $\Delta H^\circ$  and  $\Delta S^\circ$ .
- Calculate  $\Delta G^\circ$  and  $K$  at various temperatures. **Example 18.10**

## Key Equations

$$\Delta S > \frac{q}{T} \quad (\text{spontaneous process})$$

$$\Delta S = \frac{q}{T} \quad (\text{equilibrium process})$$

$$\Delta S^\circ = \sum nS^\circ(\text{products}) - \sum mS^\circ(\text{reactants})$$

$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$$

$$\Delta G^\circ = \sum n\Delta G_f^\circ(\text{products}) - \sum m\Delta G_f^\circ(\text{reactants})$$

$$\Delta G = \Delta G^\circ + RT \ln Q$$

$$\Delta G^\circ = -RT \ln K$$

$$\Delta G_T^\circ = \Delta H^\circ - T\Delta S^\circ \quad (\text{approximation for } \Delta G_T^\circ)$$

## Questions and Problems

## Self-Assessment and Review Questions

**Key:** These questions test your understanding of the ideas you worked with in the chapter. These problems vary in difficulty and often can be used for the basis of discussion.

**18.1** What is a spontaneous process? Give three examples of spontaneous processes. Give three examples of nonspontaneous processes.

**18.2** Which contains greater entropy, a quantity of frozen benzene or the same quantity of liquid benzene at the same temperature? Explain in terms of the dispersal of energy in the substance.

**18.3** State the second law of thermodynamics.

**18.4** The entropy change  $\Delta S$  for a phase transition equals  $\Delta H/T$ , where  $\Delta H$  is the enthalpy change. Why is it that the entropy change for a system in which a chemical reaction occurs spontaneously does not equal  $\Delta H/T$ ?

**18.5** Describe how the standard entropy of hydrogen gas at 25°C can be obtained from heat measurements.

**18.6** Describe what you would look for in a reaction involving gases in order to predict the sign of  $\Delta S^\circ$ . Explain.

**18.7** Define the free energy  $G$ . How is  $\Delta G$  related to  $\Delta H$  and  $\Delta S$ ?

**18.8** What is meant by the standard free-energy change  $\Delta G^\circ$  for a reaction? What is meant by the standard free energy of formation  $\Delta G_f^\circ$  of a substance?

**18.9** Explain how  $\Delta G^\circ$  can be used to decide whether a chemical equation is spontaneous in the direction written.

**18.10** What is the useful work obtained in the ideal situation in which a chemical reaction with free-energy change  $\Delta G$  is run so that it produces no entropy?

**18.11** Give an example of a chemical reaction used to obtain useful work.

**18.12** How is the concept of coupling of reactions useful in explaining how a nonspontaneous change could be made to occur?

**18.13** Explain how the free energy changes as a spontaneous reaction occurs. Show by means of a diagram how  $G$  changes with the extent of reaction.

**18.14** Explain how an equilibrium constant can be obtained from thermal data alone (that is, from measurements of heat only).

**18.15** Discuss the different sign combinations of  $\Delta H^\circ$  and  $\Delta S^\circ$  that are possible for a process carried out at constant temperature and pressure. For each combination, state

whether the process must be spontaneous or not, or whether both situations are possible. Explain.

**18.16** Consider a reaction in which  $\Delta H^\circ$  and  $\Delta S^\circ$  are positive. Suppose the reaction is nonspontaneous at room temperature. How would you estimate the temperature at which the reaction becomes spontaneous?

**18.17** Which of the following are true about the process of water making the transition from the liquid to the gaseous state at 110°C?

- a  $\Delta G > 0$ ,  $\Delta H < 0$ , and  $\Delta S = 0$
- b  $\Delta G < 0$ ,  $\Delta H > 0$ , and  $\Delta S < 0$
- c  $\Delta G > 0$ ,  $\Delta H > 0$ , and  $\Delta S > 0$
- d  $\Delta G < 0$ ,  $\Delta H < 0$ , and  $\Delta S > 0$
- e  $\Delta G < 0$ ,  $\Delta H > 0$ , and  $\Delta S > 0$

**18.18** You run a reaction that has a negative entropy change and is exothermic. Assuming that the entropy and enthalpy do not change with temperature, you could predict that as you increase the temperature:

- I. the equilibrium shifts to favor the reaction products.
- II. the reaction becomes more spontaneous.
- III.  $\Delta G$  for the reaction increases (becomes more positive).

- a I only
- b II only
- c III only
- d I and III only
- e II and III only

**18.19** A reaction has a  $\Delta G = -10.0$  kJ and a  $\Delta H = -20.0$  kJ. If  $\Delta S = -1.82 \times 10^3$  J/K, what was the temperature at which the reaction occurred?

- a 6.04 K
- b  $6.04 \times 10^{-3}$  K
- c  $5.49 \times 10^{-3}$  K
- d 5.49 K
- e 8.55 K

**18.20** Given the following information at 25°C, calculate  $\Delta G^\circ$  at 25°C for the reaction

Substance	$\Delta H_f^\circ$ (kJ/mol)	$S^\circ$ (J/mol·K)
A(g)	191	244
B(g)	70.8	300
C(g)	-197	164

- a -956 kJ
- b 956 kJ
- c -346 kJ
- d 346 kJ
- e  $-1.03 \times 10^3$  kJ

## Concept Explorations

**Key:** Concept explorations are comprehensive problems that provide a framework that will enable you to explore and learn many of the critical concepts and ideas in each chapter. If you master the concepts associated with these explorations, you will have a better understanding of many important chemistry ideas and will be more successful in solving all types of chemistry problems. These problems are well suited for group work and for use as in-class activities.

### 18.21 Thermodynamics and Spontaneous Processes

Consider a sample of water at 25°C in a beaker in a room at 50°C.

- What change do you expect to observe in the water sample? Would this be a spontaneous process or not?
- What are the enthalpy and entropy changes for this change in the water sample? (Just indicate the sign of the changes.) Explain your answers.
- Does the entropy of the water increase or decrease during the change? How do you know?
- Is there a change in free energy for the water sample? If so, indicate the sign of the free-energy change and explain how you arrived at your answer.

Consider the same sample of water, but starting at 75°C in a room at 50°C.

- What change would you observe in the water sample? Would this change be a spontaneous process or not?
- What are the enthalpy and entropy changes for the water sample? (Just indicate the sign of the changes.) Explain your answers.
- Does the entropy of the water increase or decrease during the change? How do you know?
- Is there a change in free energy for the water sample? If so, indicate the sign of the free-energy change and explain how you arrived at your answer.

Finally, consider the same sample of water, starting at 50°C in a room at 50°C.

- What would you observe in the water sample? Is this a spontaneous process?

- What are the enthalpy and entropy changes for the water sample? (Just indicate the sign of the changes.) Be sure to justify your answer.
- Did the entropy of the water increase or decrease during the change? How do you know?
- Can you determine the exact free-energy change of the water in this case? If you can make this determination, what is the significance of this value?

### 18.22 Free Energy and the Equilibrium Constant

You place the substance A(g) in a container. Consider the following reaction under standard conditions to produce the substance B(g):

For this reaction as written, the equilibrium constant is a very large, positive number.

- When A(g) reacts to give B(g), does the standard free energy ( $G^\circ$ ) of the reaction change as the reaction proceeds or does it remain constant? Explain.
- When A(g) reacts to give B(g), does the free energy ( $G$ ) of the reaction change as the reaction proceeds, or does it remain constant? Explain.
- Is this reaction spontaneous? How do you know?
- When the reaction reaches equilibrium, is the following statement true:  $\Delta G^\circ = \Delta G = 0$ ? If not, what can you say about the values of  $\Delta G^\circ$  and  $\Delta G$  when equilibrium has been reached?
- When the reaction has reached equilibrium, what can you say about the composition of the reaction mixture? Is it mostly A(g), is it mostly B(g), or is it something close to equal amounts of A(g) and B(g)?
- Now consider running the reaction in reverse:  $B(g) \rightarrow A(g)$ . For the reaction as written, what can you say about  $\Delta G^\circ$ ,  $\Delta G$ , the equilibrium constant, and the composition of the reaction mixture at equilibrium? Also, is the reaction spontaneous in this direction?

## Conceptual Problems

**Key:** These problems are designed to check your understanding of the concepts associated with some of the main topics presented in each chapter. A strong conceptual understanding of chemistry is the foundation for both applying chemical knowledge and solving chemical problems. These problems vary in level of difficulty and often can be used as a basis for group discussion.

**18.23** For each of the following statements, indicate whether it is true or false.

- A spontaneous reaction always releases heat.
- A spontaneous reaction is always a fast reaction.
- The entropy of a system always increases for a spontaneous change.
- The entropy of a system and its surroundings always increases for a spontaneous change.
- The free energy of a system always increases for a spontaneous change.

**18.24** Which of the following are spontaneous processes?

- A cube of sugar dissolves in a cup of hot tea.
- A rusty crowbar turns shiny.
- Butane from a lighter burns in air.
- A clock pendulum, initially stopped, begins swinging.
- Hydrogen and oxygen gases bubble out from a glass of pure water.

**18.25** For each of the following series of pairs, indicate which one of the pair has the greater quantity of entropy.

- 1.0 mol of carbon dioxide gas at 20°C, 1 atm, or 2.0 mol of carbon dioxide gas at 20°C, 1 atm
- 1.0 mol of butane liquid at 20°C, 10 atm, or 1.0 mol of butane gas at 20°C, 10 atm
- 1.0 mol of solid carbon dioxide at -80°C, 1 atm, or 1.0 mol of solid carbon dioxide at -90°C, 1 atm
- 25 g of solid bromine at -7°C, 1 atm, or 25 g of bromine vapor at -7°C, 1 atm

**18.26** Predict the sign of the entropy change for each of the following processes.

- A drop of food coloring diffuses throughout a glass of water.
- A tree leafs out in the spring.
- Flowers wilt and stems decompose in the fall.
- A lake freezes over in the winter.
- Rainwater on the pavement evaporates.

**18.27** Hypothetical elements A(g) and B(g) are introduced into a container and allowed to react according to the reaction  $A(g) + 2B(g) \longrightarrow AB_2(g)$ . The container depicts the reaction mixture after equilibrium has been attained.

- Is the value of  $\Delta S$  for the reaction positive, negative, or zero?
- Is the value of  $\Delta H$  for the reaction positive, negative, or zero?
- Prior to equilibrium, is the value of  $\Delta G$  for the reaction positive, negative, or zero?
- At equilibrium, is the value of  $\Delta G$  for the reaction positive, negative, or zero?

**18.28** Here is a simple experiment. Take a rubber band and stretch it. (Is this a spontaneous process? How does the Gibbs free energy change?) Place the rubber band against your lips; note how warm the rubber band has become. (How does the enthalpy change?) According to polymer chemists, the rubber band consists of long, coiled molecules. On stretching the rubber band, these long molecules uncoil and align themselves in a more ordered state. Show how the experiment given here is in accord with this molecular view of the rubber band.

**18.29** Hypothetical elements X(g) and Y(g) are introduced into a container and allowed to react according to the reaction:  $X(g) + Y(g) \longrightarrow XY(g)$ . The container depicts the reaction mixture after equilibrium has been attained.

Next, the volume of the container is doubled by rapidly moving the plunger upward.

- How will this volume change affect the equilibrium constant of the reaction?
- Immediately after the volume change, how does  $Q$  compare to the equilibrium constant and which way will the reaction proceed?
- Immediately after the volume change, are the values of  $\Delta G$  and  $\Delta S$  positive, negative, or zero for the forward reaction?

**18.30** Describe how you would expect the spontaneity ( $\Delta G^\circ$ ) for each of the following reactions to behave with a change of temperature.

- Phosgene,  $\text{COCl}_2$ , the starting material for the preparation of polyurethane plastics, decomposes as follows:

- Chlorine is added to ethylene to produce dichloroethane, a solvent:

## Practice Problems

**Key:** These problems are for practice in applying problem-solving skills. They are divided by topic, and some are keyed to exercises (see the ends of the exercises). The problems are arranged in matching pairs; the odd-numbered problem of each pair is listed first, and its answer is given in the back of the book.

### Entropy Changes

**18.31** Chloroform,  $\text{CHCl}_3$ , is a solvent and has been used as an anesthetic. The heat of vaporization of chloroform at its boiling point ( $61.2^\circ\text{C}$ ) is  $29.6 \text{ kJ/mol}$ . What is the entropy change when  $5.10 \text{ mol}$   $\text{CHCl}_3$  vaporizes at its boiling point?

**18.32** Diethyl ether (known simply as ether),  $(\text{C}_2\text{H}_5)_2\text{O}$ , is a solvent and anesthetic. The heat of vaporization of diethyl ether at its boiling point ( $35.6^\circ\text{C}$ ) is  $26.7 \text{ kJ/mol}$ . What is the entropy change when  $1.34 \text{ mol}$   $(\text{C}_2\text{H}_5)_2\text{O}$  vaporizes at its boiling point?

**18.33** The enthalpy change when liquid methanol,  $\text{CH}_3\text{OH}$ , vaporizes at  $25^\circ\text{C}$  is  $38.0 \text{ kJ/mol}$ . What is the entropy

change when  $1.00 \text{ mol}$  of vapor in equilibrium with liquid condenses to liquid at  $25^\circ\text{C}$ ? The entropy of this vapor at  $25^\circ\text{C}$  is  $255 \text{ J/(mol}\cdot\text{K)}$ . What is the entropy of the liquid at this temperature?

**18.34** The heat of vaporization of carbon disulfide,  $\text{CS}_2$ , at  $25^\circ\text{C}$  is  $27.2 \text{ kJ/mol}$ . What is the entropy change when  $1.00 \text{ mol}$  of vapor in equilibrium with liquid condenses to liquid at  $25^\circ\text{C}$ ? The entropy of this vapor at  $25^\circ\text{C}$  is  $243 \text{ J/(mol}\cdot\text{K)}$ . What is the entropy of the liquid at this temperature?

**18.35** Predict the sign of  $\Delta S^\circ$ , if possible, for each of the following reactions. If you cannot predict the sign for any reaction, state why.

- $\text{HCl}(g) + \text{NH}_3(g) \longrightarrow \text{NH}_4\text{Cl}(s)$
- $\text{N}_2(g) + 3\text{H}_2(g) \longrightarrow 2\text{NH}_3(g)$
- $2\text{SO}_2(g) + \text{O}_2(g) \longrightarrow 2\text{SO}_3(g)$
- $\text{CH}_3\text{OH}(l) + \frac{3}{2}\text{O}_2(g) \longrightarrow \text{CO}_2(g) + 2\text{H}_2\text{O}(g)$

**18.36** Predict the sign of  $\Delta S^\circ$ , if possible, for each of the following reactions. If you cannot predict the sign for any reaction, state why.

## 635c

## Thermodynamics and Equilibrium

**18.37** Calculate  $\Delta S^\circ$  for the following reactions, using standard entropy values.

**18.38** Calculate  $\Delta S^\circ$  for the following reactions, using standard entropy values.

**18.39** Calculate  $\Delta S^\circ$  for the reaction

See Table 18.1 for values of standard entropies. Does the entropy of the chemical system increase or decrease as you expect? Explain.

**18.40** What is the change in entropy,  $\Delta S^\circ$ , for the reaction

See Table 18.1 for values of standard entropies. Does the entropy of the chemical system increase or decrease as you expect? Explain.

### Free-Energy Change and Spontaneity

**18.41** Using enthalpies of formation (Appendix C), calculate  $\Delta H^\circ$  for the following reaction at  $25^\circ\text{C}$ . Also calculate  $\Delta S^\circ$  for this reaction from standard entropies at  $25^\circ\text{C}$ . Use these values to calculate  $\Delta G^\circ$  for the reaction at this temperature.

**18.42** Using enthalpies of formation (Appendix C), calculate  $\Delta H^\circ$  for the following reaction at  $25^\circ\text{C}$ . Also calculate  $\Delta S^\circ$  for this reaction from standard entropies at  $25^\circ\text{C}$ . Use these values to calculate  $\Delta G^\circ$  for the reaction at this temperature.

**18.43** The free energy of formation of one mole of compound refers to a particular chemical equation. For each of the following, write that equation.

**18.44** The free energy of formation of one mole of compound refers to a particular chemical equation. For each of the following, write that equation.

**18.45** Calculate the standard free energy of the following reactions at  $25^\circ\text{C}$ , using standard free energies of formation.

**18.46** Calculate the standard free energy of the following reactions at  $25^\circ\text{C}$ , using standard free energies of formation.

**18.47** On the basis of  $\Delta G^\circ$  for each of the following reactions, decide whether the reaction is spontaneous or nonspontaneous as written. Or, if you expect an equilibrium mixture with significant amounts of both reactants and products, say so.

**18.48** For each of the following reactions, state whether the reaction is spontaneous or nonspontaneous as written or is easily reversible (that is, is a mixture with significant amounts of reactants and products).

**18.49** Calculate  $\Delta H^\circ$  and  $\Delta G^\circ$  for the following reactions at  $25^\circ\text{C}$ , using thermodynamic data from Appendix C; interpret the signs of  $\Delta H^\circ$  and  $\Delta G^\circ$ .

**18.50** Calculate  $\Delta H^\circ$  and  $\Delta G^\circ$  for the following reactions at  $25^\circ\text{C}$ , using thermodynamic data from Appendix C; interpret the signs of  $\Delta H^\circ$  and  $\Delta G^\circ$ .

### Maximum Work

**18.51** Consider the reaction of 2 mol  $\text{H}_2(g)$  at  $25^\circ\text{C}$  and 1 atm with 1 mol  $\text{O}_2(g)$  at the same temperature and pressure to produce liquid water at these conditions. If this reaction is run in a controlled way to generate work, what is the maximum useful work that can be obtained? How much entropy is produced in this case?

**18.52** Consider the reaction of 1 mol  $\text{H}_2(g)$  at  $25^\circ\text{C}$  and 1 atm with 1 mol  $\text{Br}_2(l)$  at the same temperature and pressure to produce gaseous  $\text{HBr}$  at these conditions. If this reaction is run in a controlled way to generate work, what is the maximum useful work that can be obtained? How much entropy is produced in this case?

**18.53** What is the maximum work that could be obtained from 4.95 g of zinc metal in the following reaction at  $25^\circ\text{C}$ ?

**18.54** What is the maximum work that could be obtained from 3.65 g of zinc metal in the following reaction at  $25^\circ\text{C}$ ?

### Calculation of Equilibrium Constants

**18.55** Give the expression for the thermodynamic equilibrium constant for each of the following reactions.

- a  $\text{CO}(g) + \text{H}_2\text{O}(g) \rightleftharpoons \text{CO}_2(g) + \text{H}_2(g)$   
 b  $\text{Mg}(\text{OH})_2(s) \rightleftharpoons \text{Mg}^{2+}(aq) + 2\text{OH}^-(aq)$   
 c  $2\text{Li}(s) + 2\text{H}_2\text{O}(l) \rightleftharpoons 2\text{Li}^+(aq) + 2\text{OH}^-(aq) + \text{H}_2(g)$

**18.56** Write the expression for the thermodynamic equilibrium constant for each of the following reactions.

- a  $\text{CO}(g) + 2\text{H}_2(g) \rightleftharpoons \text{CH}_3\text{OH}(g)$   
 b  $2\text{Ag}^+(aq) + \text{CrO}_4^{2-}(aq) \rightleftharpoons \text{Ag}_2\text{CrO}_4(s)$   
 c  $\text{CaCO}_3(s) + 2\text{H}^+(aq) \rightleftharpoons \text{Ca}^{2+}(aq) + \text{H}_2\text{O}(l) + \text{CO}_2(g)$

**18.57** What is the standard free-energy change  $\Delta G^\circ$  at 25°C for the following reaction? Obtain necessary information from Appendix C.

What is the value of the thermodynamic equilibrium constant  $K$ ?

**18.58** What is the standard free-energy change  $\Delta G^\circ$  at 25°C for the following reaction? See Table 18.2 for data.

Calculate the value of the thermodynamic equilibrium constant  $K$ .

**18.59** Calculate the standard free-energy change and the equilibrium constant  $K_p$  for the following reaction at 25°C. See Table 18.2 for data.

**18.60** Calculate the standard free-energy change and the equilibrium constant  $K_p$  for the following reaction at 25°C. See Appendix C for data.

**18.61** Obtain the equilibrium constant  $K_c$  at 25°C from the free-energy change for the reaction

See Appendix C for data.

**18.62** Calculate the equilibrium constant  $K_c$  at 25°C from the free-energy change for the following reaction:

See Appendix C for data.

### Free Energy and Temperature Change

**18.63** Use data given in Tables 6.2 and 18.1 to obtain the value of  $K_p$  at 1000°C for the reaction

Carbon monoxide is known to form during combustion of carbon at high temperatures. Do the data agree with this? Explain.

**18.64** Use data given in Tables 6.2 and 18.1 to obtain the value of  $K_p$  at 2000°C for the reaction

Nitric oxide is known to form in hot flames in air, which is a mixture of  $\text{N}_2$  and  $\text{O}_2$ . It is present in auto exhaust from this reaction. Are the data in agreement with this result? Explain.

**18.65** Sodium carbonate,  $\text{Na}_2\text{CO}_3$ , can be prepared by heating sodium hydrogen carbonate,  $\text{NaHCO}_3$ .

Estimate the temperature at which  $\text{NaHCO}_3$  decomposes to products at 1 atm. See Appendix C for data.

**18.66** Oxygen was first prepared by heating mercury(II) oxide,  $\text{HgO}$ .

Estimate the temperature at which  $\text{HgO}$  decomposes to  $\text{O}_2$  at 1 atm. See Appendix C for data.

## General Problems

**Key:** These problems provide more practice but are not divided by topic or keyed to exercises. Each section ends with essay questions, each of which is color coded to refer to the *A Chemist Looks at Life Science* (pink) chapter essay on which it is based. Odd-numbered problems and the even-numbered problems that follow are similar; answers to all odd-numbered problems except the essay questions are given in the back of the book.

**18.67** Find the sign of  $\Delta S^\circ$  for the reaction

The reaction is endothermic and nonspontaneous at 25°C. Explain the spontaneity of the reaction in terms of enthalpy and entropy changes as the temperature increases.

**18.68** The combustion of acetylene,  $\text{C}_2\text{H}_2$ , is a spontaneous reaction given by the equation

As expected for a combustion, the reaction is exothermic. What is the sign of  $\Delta H^\circ$ ? What do you expect for the sign

of  $\Delta S^\circ$ ? Explain the spontaneity of the reaction in terms of the enthalpy and entropy changes.

**18.69** Estimate the value of  $\Delta H^\circ$  for the following reaction from bond energies (Table 9.5).

Is the reaction exothermic or endothermic? Note that the reaction involves the breaking of symmetrical molecules ( $\text{H}_2$  and  $\text{Cl}_2$ ) and the formation of a less symmetrical product ( $\text{HCl}$ ). From this, would you expect  $\Delta S^\circ$  to be positive or negative? Comment on the spontaneity of the reaction in terms of the changes in enthalpy and entropy.

**18.70** Compare the energies of the bonds broken and those formed (see Table 9.5) for the reaction

From this, conclude whether the reaction is exothermic or endothermic. What is the sign of  $\Delta S^\circ$ ? Explain. The reaction is spontaneous at 25°C. Explain this in terms of the enthalpy and entropy changes.

**18.71** Acetic acid,  $\text{CH}_3\text{COOH}$ , freezes at  $16.6^\circ\text{C}$ . The heat of fusion,  $\Delta H_{\text{fus}}$ , is  $69.0 \text{ J/g}$ . What is the change of entropy,  $\Delta S$ , when 1 mol of liquid acetic acid freezes to the solid?

**18.72** Acetone,  $\text{CH}_3\text{COCH}_3$ , boils at  $56^\circ\text{C}$ . The heat of vaporization of acetone at this temperature is  $29.1 \text{ kJ/mol}$ . What is the entropy change when 1 mol of liquid acetone vaporizes at  $56^\circ\text{C}$ ?

**18.73** Without doing any calculations, decide what the sign of  $\Delta S^\circ$  will be for each of the following reactions.

- a**  $2\text{LiOH}(aq) + \text{CO}_2(g) \longrightarrow \text{Li}_2\text{CO}_3(aq) + \text{H}_2\text{O}(l)$   
**b**  $(\text{NH}_4)_2\text{Cr}_2\text{O}_7(s) \longrightarrow \text{N}_2(g) + 4\text{H}_2\text{O}(g) + \text{Cr}_2\text{O}_3(s)$   
**c**  $2\text{N}_2\text{O}_5(g) \longrightarrow 4\text{NO}_2(g) + \text{O}_2(g)$   
**d**  $\text{O}_2(g) + 2\text{F}_2(g) \longrightarrow 2\text{OF}_2(g)$

**18.74** For each of the following reactions, decide whether there is an increase or a decrease in entropy. Why do you think so? (No calculations are needed.)

- a**  $\text{N}_2(g) + 3\text{H}_2(g) \longrightarrow 2\text{NH}_3(g)$   
**b**  $\text{NH}_4\text{Cl}(s) \longrightarrow \text{NH}_3(g) + \text{HCl}(g)$   
**c**  $\text{CO}(g) + 2\text{H}_2(g) \longrightarrow \text{CH}_3\text{OH}(l)$   
**d**  $\text{Li}_3\text{N}(s) + 3\text{H}_2\text{O}(l) \longrightarrow 3\text{LiOH}(aq) + \text{NH}_3(g)$

**18.75** The following equation shows how nitrogen dioxide reacts with water to produce nitric acid:

Predict the sign of  $\Delta S^\circ$  for this reaction.

**18.76** Ethanol burns in air or oxygen according to the equation

Predict the sign of  $\Delta S^\circ$  for this reaction.

**18.77** Acetic acid in vinegar results from the bacterial oxidation of ethanol.

What is  $\Delta S^\circ$  for this reaction? Use standard entropy values. (See Appendix C for data.)

**18.78** Methanol is produced commercially from carbon monoxide and hydrogen.

What is  $\Delta S^\circ$  for this reaction? Use standard entropy values.

**18.79** Is the following reaction spontaneous as written? Explain. Do whatever calculation is needed to answer the question.

**18.80** Is the following reaction spontaneous as written? Explain. Do whatever calculation is needed to answer the question.

**18.81** The reaction

is nonspontaneous at room temperature but becomes spontaneous at a much higher temperature. What can you conclude from this about the signs of  $\Delta H^\circ$  and  $\Delta S^\circ$ , assuming that the enthalpy and entropy changes are not greatly affected by the temperature change? Explain your reasoning.

**18.82** The reaction

is spontaneous at room temperature but becomes nonspontaneous at a much higher temperature. From this fact alone, obtain the signs of  $\Delta H^\circ$  and  $\Delta S^\circ$ , assuming that  $\Delta H^\circ$  and  $\Delta S^\circ$  do not change much with temperature. Explain your reasoning.

**18.83** Calculate  $\Delta G^\circ$  at  $25^\circ\text{C}$  for the reaction

See Appendix C for values of  $\Delta G_f^\circ$ . What is the value of the solubility product constant,  $K_{\text{sp}}$ , for this reaction at  $25^\circ\text{C}$ ?

**18.84** Calculate  $\Delta G^\circ$  at  $25^\circ\text{C}$  for the reaction

See Appendix C for values of  $\Delta G_f^\circ$ . What is the value of the solubility product constant,  $K_{\text{sp}}$ , for this reaction at  $25^\circ\text{C}$ ?

**18.85** Consider the decomposition of phosgene,  $\text{COCl}_2$ .

Calculate  $\Delta H^\circ$  and  $\Delta S^\circ$  at  $25^\circ\text{C}$  for this reaction. See Appendix C for data. What is  $\Delta G^\circ$  at  $25^\circ\text{C}$ ? Assume that  $\Delta H^\circ$  and  $\Delta S^\circ$  are constant with respect to a change of temperature. Now calculate  $\Delta G^\circ$  at  $800^\circ\text{C}$ . Compare the two values of  $\Delta G^\circ$ . Briefly discuss the spontaneity of the reaction at  $25^\circ\text{C}$  and at  $800^\circ\text{C}$ .

**18.86** Consider the reaction

Calculate  $\Delta H^\circ$ ,  $\Delta S^\circ$ , and  $\Delta G^\circ$  at  $25^\circ\text{C}$  for this reaction. Assume  $\Delta H^\circ$  and  $\Delta S^\circ$  are constant with respect to a change of temperature. Now calculate  $\Delta G^\circ$  at  $650^\circ\text{C}$ . Compare the two values of  $\Delta G^\circ$ . Briefly discuss the spontaneity of the reaction at  $25^\circ\text{C}$  and at  $650^\circ\text{C}$ .

**18.87 a** From a consideration of the following reactions, calculate  $\Delta H_f^\circ$  for methane,  $\text{CH}_4(g)$ .

**b** From appropriate entropy data, calculate  $\Delta S^\circ$  for the formation of methane from the elements.

**c** Using the information from above, calculate  $\Delta G_f^\circ$  for methane at  $25^\circ\text{C}$ .

**18.88 a** From a consideration of the following reactions, calculate  $\Delta H_f^\circ$  for ethane,  $\text{C}_2\text{H}_6(g)$ .

$$\Delta H^\circ = -204 \text{ kJ}$$

$$\Delta H^\circ = -348 \text{ kJ}$$

- b** From appropriate entropy data, calculate  $\Delta S^\circ$  for the formation of ethane from the elements.
- c** Using the information from above, calculate  $\Delta G_f^\circ$  for ethane at 25°C.

**18.89** For the reaction

the value of  $\Delta G^\circ$  is  $-702.2$  kJ at 25°C. Other data are as follows:

	$\Delta H_f^\circ$ (kJ/mol) at 25°C	$S^\circ$ (J/mol·K) at 25°C
CH <sub>3</sub> OH(l)	-238.7	126.8
H <sub>2</sub> O(l)	-285.8	70.0
CO <sub>2</sub> (g)	-393.5	213.7

Calculate the standard entropy,  $S^\circ$ , per mole of O<sub>2</sub>(g).

**18.90** For the reaction

the value of  $\Delta G^\circ$  is  $-618.8$  kJ/mol at 25°C. Other data are as follows:

	$\Delta H_f^\circ$ (kJ/mol) at 25°C	$S^\circ$ (J/mol·K) at 25°C
HCHO	-117.0	219.0
H <sub>2</sub> O(g)	-241.8	188.7
CO <sub>2</sub> (g)	-393.5	213.7
O <sub>3</sub> (g)	142.7	?

Calculate the entropy,  $S^\circ$ , per mole of O<sub>3</sub>(g).

**18.91** Tin(IV) oxide can be reacted with either hydrogen or carbon to form tin and water vapor or carbon dioxide, respectively. See Appendix C for data.

- a** Calculate  $\Delta H^\circ$  and  $\Delta S^\circ$  at 25°C for the reaction of SnO<sub>2</sub> with H<sub>2</sub> and for the reaction of SnO<sub>2</sub> with C.
- b** At what temperature will each of these processes become spontaneous?
- c** Industrially, which process is preferred? Why?

**18.92** Tungsten is usually produced by the reduction of WO<sub>3</sub> with hydrogen:

Consider the following data:

	WO <sub>3</sub> (s)	H <sub>2</sub> O(g)
$\Delta H_f^\circ$ (kJ/mol)	-839.9	-241.8
$\Delta G_f^\circ$ (kJ/mol)	-763.1	-228.6

- a** Is  $K > 1$  or  $< 1$  at 25°C? Explain your answer.
- b** What is the value of  $\Delta S^\circ$  at 25°C?
- c** What is the temperature at which  $\Delta G^\circ$  equals zero for this reaction at 1 atm pressure?
- d** What is the driving force of this reaction?

**18.93** For the decomposition of formic acid,

$\Delta H^\circ = +29$  kJ/mol at 25°C.

- a** Does the tendency of this reaction to proceed to a state of minimum energy favor the formation of water and carbon monoxide or formic acid? Explain.

- b** Does the tendency of this reaction to proceed to a state of maximum entropy favor the formation of products or reactants? Explain.

**18.94** **a** Why are some reactions exothermic and others endothermic?

- b** Discuss the driving force in a spontaneous reaction that is highly exothermic and in one that is endothermic.

**18.95** For the reaction

$\Delta H^\circ$  and  $\Delta G^\circ$  are negative and  $\Delta S^\circ$  is positive.

- a** At equilibrium, will reactants or products predominate? Why?
- b** Why must the reaction system be heated in order to produce copper(I) sulfide?

**18.96** For the reaction

the products have a lower free energy than the reactants.

- a** Predict the sign of the entropy change for this reaction. Explain.
- b** Predict whether reactants or products would predominate in an equilibrium mixture. Why?
- c** How can you account for the fact that a mixture of the reactants must be heated in the presence of a catalyst in order to produce products?

**18.97** When 1.000 g of gaseous butane, C<sub>4</sub>H<sub>10</sub>, is burned at 25°C and 1.00 atm pressure, H<sub>2</sub>O(l) and CO<sub>2</sub>(g) are formed with the evolution of 49.50 kJ of heat.

- a** Calculate the molar enthalpy of formation of butane. (Use enthalpy of formation data for H<sub>2</sub>O and CO<sub>2</sub>.)
- b**  $\Delta G_f^\circ$  of butane is  $-17.2$  kJ/mol. What is  $\Delta G^\circ$  for the combustion of 1 mol butane?
- c** From a and b, calculate  $\Delta S^\circ$  for the combustion of 1 mol butane.

**18.98** When 1.000 g of ethylene glycol, C<sub>2</sub>H<sub>6</sub>O<sub>2</sub>, is burned at 25°C and 1.00 atmosphere pressure, H<sub>2</sub>O(l) and CO<sub>2</sub>(g) are formed with the evolution of 19.18 kJ of heat.

- a** Calculate the molar enthalpy of formation of ethylene glycol. (It will be necessary to use data from Appendix C.)
- b**  $\Delta G_f^\circ$  of ethylene glycol is  $-322.5$  kJ/mol. What is  $\Delta G^\circ$  for the combustion of 1 mol ethylene glycol?
- c** What is  $\Delta S^\circ$  for the combustion of 1 mol ethylene glycol?

**18.99** **a** Calculate  $K_1$  at 25°C for phosphoric acid:

	H <sub>3</sub> PO <sub>4</sub> (aq)	H <sup>+</sup> (aq)	H <sub>2</sub> PO <sub>4</sub> <sup>-</sup> (aq)
$\Delta H_f^\circ$ (kJ/mol)	-1288.3	0	-1285
$S^\circ$ (J/mol·K)	158.2	0	89

- b** Which thermodynamic factor is the most significant in accounting for the fact that phosphoric acid is a weak acid? Why?

**18.100** **a** Calculate  $K_1$  at 25°C for sulfurous acid:

	H <sub>2</sub> SO <sub>3</sub> (aq)	H <sup>+</sup> (aq)	HSO <sub>3</sub> <sup>-</sup> (aq)
$\Delta H_f^\circ$ (kJ/mol)	-608.8	0	-626.2
$S^\circ$ (J/mol·K)	232.2	0	139.8

**b** Which thermodynamic factor is the most significant in accounting for the fact that sulfurous acid is a weak acid? Why?

**18.101** The direct reaction of iron(III) oxide,  $\text{Fe}_2\text{O}_3$ , to give iron and oxygen gas is a nonspontaneous reaction; normally, iron combines with oxygen to give rust (the oxide). Yet we do change iron(III) oxide, as iron ore, into iron metal. How is this possible? Explain.

**18.102** Adenosine triphosphate (ATP) is often referred to as a biological “energy” source. What does this mean?

Explain how ATP is used in biological organisms to produce proteins from amino acids.

## Strategy Problems

**Key:** As noted earlier, all of the practice and general problems are matched pairs. This section is a selection of problems that are not in matched-pair format. These challenging problems require that you employ many of the concepts and strategies that were developed in the chapter. In some cases, you will have to integrate several concepts and operational skills in order to solve the problem successfully.

**18.103** Consider the reaction in which hydrazine vapor decomposes to its elements:

Use data from Appendix C to answer the following questions.

- What is the standard enthalpy change for this reaction at  $25^\circ\text{C}$ ?
- Calculate the standard entropy change at  $25^\circ\text{C}$ . Does the sign of the entropy change agree with what you would expect? Explain.
- Describe the spontaneity or nonspontaneity of the reaction at various temperatures.
- What happens to  $\Delta G^\circ$  as you lower the temperature? Would this reaction give greater product at higher or at lower temperature? Explain.

**18.104** Consider the reaction for the formation of  $\text{H}_2\text{O}(g)$  from its elements. Use the data in Appendix C to answer the following questions.

- What is the standard enthalpy of formation of  $\text{H}_2\text{O}(g)$  at  $25^\circ\text{C}$ ?
- What is the standard entropy of formation of  $\text{H}_2\text{O}(g)$  at  $25^\circ\text{C}$ ?
- Use these values to calculate the standard free energy of formation of  $\text{H}_2\text{O}(g)$  at  $25^\circ\text{C}$ . Check this value against the one given in Appendix C.
- A student obtained  $\Delta G_f^\circ$  for  $\text{H}_2\text{O}(g)$  by calculating  $\Delta H_f^\circ - TS^\circ$ , using  $\Delta H_f^\circ$  and  $S^\circ$  for  $\text{H}_2\text{O}(g)$  from Appendix C. Is this correct? Explain.

**18.105** Acetone,  $\text{CH}_3\text{COCH}_3$ , is a fragrant liquid that is used as a solvent for lacquers, paint removers, and nail polish remover. It burns in oxygen to give carbon dioxide and water:

If the standard free-energy change for this reaction is  $-1739 \text{ kJ/mol}$ , what is the standard free energy of formation of acetone? Use data from Appendix C.

**18.106** Cobalt(II) chloride hexahydrate,  $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ , is a bright pink compound, but in the presence of very dry air it loses water vapor to the air to produce the light blue

anhydrous salt  $\text{CoCl}_2$ . Calculate the standard free-energy change for the reaction at  $25^\circ\text{C}$ :

Here are some thermodynamic data at  $25^\circ\text{C}$ :

	$\Delta H_f^\circ$ (kJ/mol)	$\Delta G_f^\circ$ (kJ/mol)	$S^\circ$ (J/mol·K)
$\text{CoCl}_2(s)$	-313.	-270.	109.
$\text{CoCl}_2 \cdot 6\text{H}_2\text{O}(s)$	-2115.	-1725.	343.

What is the partial pressure of water vapor in equilibrium with the anhydrous salt and the hexahydrate at  $25^\circ\text{C}$ ? (Give the value in mmHg.) What is the relative humidity of air that has this partial pressure of water? The relative humidity of a sample of air is

$$\text{Relative humidity} = \frac{\text{partial pressure of H}_2\text{O}(g) \text{ in air}}{\text{vapor pressure of water}} \times 100\%$$

What do you expect to happen to the equilibrium partial pressure over the hexahydrate as the temperature is raised? Explain.

**18.107** An experimenter placed 1.000 mol of  $\text{H}_2$  and 1.000 mol of  $\text{I}_2$  in a 1.000-L flask. The substances reacted to produce hydrogen iodide:

When the contents of the flask came to equilibrium at  $458^\circ\text{C}$ , the experimenter found that it contained 0.225 mol  $\text{H}_2$ , 0.225 mol  $\text{I}_2$ , and 1.550 mol  $\text{HI}$ .

- Calculate the standard free-energy change for the reaction at  $458^\circ\text{C}$ .
- Assume that the standard enthalpy change for the reaction at  $458^\circ\text{C}$  is the same as it is at  $298^\circ\text{C}$ . Calculate the standard entropy change for the reaction at  $458^\circ\text{C}$ .

**18.108** Hydrogen gas and iodine vapor react to produce hydrogen iodide gas:

Calculate the free-energy change  $\Delta G$  for the following two conditions, at  $25^\circ\text{C}$ . Which one is closer to equilibrium? Explain.

- The partial pressures of  $\text{H}_2(g)$ ,  $\text{I}_2(g)$ , and  $\text{HI}(g)$  are each  $\frac{1}{3}$  atm.
- The partial pressures of  $\text{H}_2(g)$  and  $\text{I}_2(g)$  are each  $\frac{1}{3}$  atm; the partial pressure of  $\text{HI}(g)$  is  $\frac{1}{90}$  atm.

**18.109** Silver carbonate,  $\text{Ag}_2\text{CO}_3$ , is a light yellow compound that decomposes when heated to give silver oxide and carbon dioxide:

A researcher measured the partial pressure of carbon dioxide over a sample of silver carbonate at 220°C and found that it was 1.37 atm. Calculate the partial pressure of carbon dioxide at 25°C. The standard enthalpies of formation of silver carbonate and silver oxide at 25°C are  $-505.9$  kJ/mol and  $-31.05$  kJ/mol, respectively. Make any reasonable assumptions in your calculations. State the assumptions that you make, and note why you think they are reasonable.

**18.110** Sulfur is produced in volcanic gases by the reaction of hydrogen sulfide with sulfur dioxide:

A particular sample of volcanic gas at 1.00 atm has a partial pressure of sulfur dioxide of 89 mmHg. If this gas at 1170°C also contains hydrogen sulfide and water vapor in equilibrium with rhombic sulfur, what is the ratio of the partial pressure of water vapor to the partial pressure of hydrogen sulfide? Use any reasonable approximations.

**18.111** Adenosine triphosphate, ATP, is used as a free-energy source by biological cells. (See the essay on page 624.) ATP hydrolyzes in the presence of enzymes to give ADP:

Consider a hypothetical biochemical reaction of molecule A to give molecule B:

**a** Calculate the ratio  $[\text{B}]/[\text{A}]$  at 25°C at equilibrium.

**b** Now consider this reaction “coupled” to the reaction for the hydrolysis of ATP:

If a cell maintains a high ratio of ATP to ADP and  $\text{H}_2\text{PO}_4^-$  by continuously making ATP, the conversion of A to B can be made highly spontaneous. A characteristic value of this ratio is

$$\frac{[\text{ATP}]}{[\text{ADP}][\text{H}_2\text{PO}_4^-]} = 500$$

Calculate the ratio  $[\text{B}]/[\text{A}]$  in this case and compare it with the uncoupled reaction. Compared with the uncoupled reaction, how much larger is this ratio when coupled to the hydrolysis of ATP?

**18.112** A car has been fitted with an internal combustion engine that uses propane as a fuel.

What is the maximum work that you can obtain from 1.00 kg of propane,  $\text{C}_3\text{H}_8$ ? Suppose the car is driving uphill. What is the maximum height, in miles, that the car could go to, assuming that the car’s mass is 4000. lb? The work done in moving a mass,  $m$ , up to a height  $h$  is  $mgh$ , where  $g$  is the constant acceleration of gravity (equal to  $9.81 \text{ m/s}^2$ ).

**18.113** Given the following information, calculate the standard free energy of formation of  $\text{OH}^-(aq)$  at 25°C and compare the value you calculate with that given in Table 18.2. At 25°C, the pH of pure water is 7.00 and the free

energy of formation of  $\text{H}_2\text{O}(aq)$  is  $-231.71$  kJ/mol. Note that  $\Delta G_f^\circ$  for  $\text{H}^+(aq)$  equals zero by convention.

**18.114** A quantity of strong acid is added to pure water to give a solution that is  $0.100 \text{ M H}^+$ . Calculate  $Q$  for the following reaction just as the  $\text{H}^+$  ion is added and before equilibrium is established.

What is the value of the free-energy change,  $\Delta G$ , for this reaction starting from these nonstandard conditions?

**18.115** Sodium acetate crystallizes from a supersaturated solution (see Figure 12.4). What can you say about the sign of  $\Delta G^\circ$ ? What would you expect for the sign of  $\Delta S^\circ$ ? What about the sign of  $\Delta H^\circ$ ? Is the crystallization exothermic or endothermic? Explain your answers.

**18.116** According to a source, lithium peroxide ( $\text{Li}_2\text{O}_2$ ) decomposes to lithium oxide ( $\text{Li}_2\text{O}$ ) and oxygen gas at about 195°C. If the standard enthalpy change for this decomposition is 33.9 kJ/mol, what would you give as an estimate for the standard entropy change for this reaction? Explain.

**18.117** Tetrachloromethane (carbon tetrachloride),  $\text{CCl}_4$ , has a normal boiling point of 76.7°C and an enthalpy of vaporization,  $\Delta H_{\text{vap}}^\circ$ , of 29.82 kJ/mol. Estimate the entropy of vaporization,  $\Delta S_{\text{vap}}^\circ$ . Estimate the free energy of vaporization,  $\Delta G_{\text{vap}}^\circ$ , at 25°C.

**18.118** Ammonia,  $\text{NH}_3$ , is produced from its elements in the industrial Haber process. Calculate  $\Delta H^\circ$ ,  $\Delta G^\circ$ , and  $\Delta S^\circ$  at 25°C. See Appendix C for data. The industrial process is run at temperatures around 450°C. Would the equilibrium yield be more or less at 25°C? Explain. Estimate the equilibrium constant  $K_p$  at 450°C.

**18.119** A truck weighing 1600 kg uses natural gas as fuel. Natural gas is mainly methane,  $\text{CH}_4$ , and though it is normally a gas, it is stored in a tank as compressed liquid. Assume that the fuel is methane gas and that it burns completely in the engine to carbon dioxide gas and water vapor. What is the maximum work that 1.00 mol  $\text{CH}_4(g)$  can do if it burns at 25°C? What would be the maximum height that this truck could travel up a hill on 1.00 m<sup>3</sup> of liquid methane fuel? The density of liquid methane is 416 kg/m<sup>3</sup>. (Note that the potential energy of a mass  $m$  raised to a height  $h$  is  $mgh$ , where  $g$  is the acceleration of gravity and equals  $9.81 \text{ m/s}^2$ .)

**18.120** Consider the reaction of methane,  $\text{CH}_4(g)$ , with oxygen,  $\text{O}_2(g)$ , to produce carbon dioxide,  $\text{CO}_2(g)$ , and water,  $\text{H}_2\text{O}(l)$ , taking place in a closed container. What is the entropy change at 25°C due to the reaction of 1.00 mol  $\text{CH}_4$  in the container? When this reaction occurs, heat is produced. Suppose this heat leaves the container at 25°C. What is the entropy that flows out of the container as a result of this heat flow? What is the net change of entropy of the container and its surroundings?

**18.121** Hydrogen gas is important industrially and has been used as a fuel. Water is an obvious source of hydrogen, but it requires free energy to break water into its elements. What is the standard free-energy change for the reaction at 25°C:

Is this reaction spontaneous or not? One way to obtain the free energy needed for the production of hydrogen is to effectively couple this reaction to one that is quite

spontaneous. Consider the reaction in which carbon reacts with oxygen to form carbon monoxide:

What is the standard free-energy change for this reaction at 25°C? Is the reaction spontaneous or not? See if you can effectively couple these two reactions to get one that is spontaneous and would be useful as a way to manufacture hydrogen. What is the standard free-energy change for this reaction?

**18.122** Coal is used as a fuel in some electric-generating plants. Coal is a complex material, but for simplicity we may consider it to be a form of carbon. The energy that can be derived from a fuel is sometimes compared with the enthalpy of the combustion reaction:

Calculate the standard enthalpy change for this reaction at 25°C. Actually, only a fraction of the heat from this reaction is available to produce electric energy. In electric

generating plants, this reaction is used to generate heat for a steam engine, which turns the generator. Basically the steam engine is a type of heat engine in which steam enters the engine at high temperature ( $T_h$ ), work is done, and the steam then exits at a lower temperature ( $T_l$ ). The maximum fraction,  $f$ , of heat available to produce useful energy depends on the difference between these temperatures (expressed in kelvins),  $f = (T_h - T_l)/T_h$ . What is the maximum heat energy available for useful work from the combustion of 1.00 mol of  $\text{C}(s)$  to  $\text{CO}_2(g)$ ? (Assume the value of  $\Delta H^\circ$  calculated at 25°C for the heat obtained in the generator.) It is possible to consider more efficient ways to obtain useful energy from a fuel. For example, methane can be burned in a fuel cell to generate electricity directly. The maximum useful energy obtained in these cases is the maximum work, which equals the free-energy change. Calculate the standard free-energy change for the combustion of 1.00 mol of  $\text{C}(s)$  to  $\text{CO}_2(g)$ . Compare this value with the maximum obtained with the heat engine described here.

## Capstone Problems

**Key:** The problems under this heading combine skills, strategies, and concepts learned in previous chapters with those introduced in the current one.

**18.123** Hydrogen bromide dissociates into its gaseous elements,  $\text{H}_2$  and  $\text{Br}_2$ , at elevated temperatures. Calculate the percent dissociation at 317°C and 1.00 atm. What would be the percent dissociation at 317°C and 10.0 atm? Use data from Appendix C and any reasonable approximation to obtain  $K$ .

**18.124** Hydrogen gas and iodine gas react to form hydrogen iodide. If 0.500 mol  $\text{H}_2$  and 1.00 mol  $\text{I}_2$  are placed in a closed 10.0-L vessel, what is the mole fraction of HI in the mixture when equilibrium is reached at 205°C? Use data from Appendix C and any reasonable approximations to obtain  $K$ .

**18.125** A 20.0-L vessel is filled with 1.00 mol of ammonia,  $\text{NH}_3$ . What percent of ammonia dissociates to the elements if equilibrium is reached at 402°C? Use data from Appendix C and make any reasonable approximations to obtain  $K$ .

**18.126** A 25.0-L vessel is filled with 0.0100 mol CO and 0.0300 mol  $\text{H}_2$ . How many moles of  $\text{CH}_4$  and how many moles of  $\text{H}_2\text{O}$  are produced when equilibrium is reached at 785°C? Use data from Appendix C and make any reasonable approximations to obtain  $K$ .

**18.127**  $K_a$  for acetic acid at 25.0°C is  $1.754 \times 10^{-5}$ . At 55.0°C,  $K_a$  is  $1.625 \times 10^{-5}$ . What are  $\Delta H^\circ$  and  $\Delta S^\circ$  for the ionization of acetic acid?

**18.128**  $K_{sp}$  for silver chloride at 25.0°C is  $1.782 \times 10^{-10}$ . At 35.0°C,  $K_{sp}$  is  $4.159 \times 10^{-10}$ . What are  $\Delta H^\circ$  and  $\Delta S^\circ$  for the reaction?

- 19.10** Aqueous Electrolysis
- 19.11** Stoichiometry of Electrolysis

The first battery was invented by Alessandro Volta about 1800. He assembled a pile consisting of pairs of zinc and silver disks separated by paper disks soaked in salt water. With a tall pile, he could detect a weak electric shock when he touched the two ends of the pile. Later Volta showed that any two different metals could be used to make such a voltaic pile (Figure 19.1).

A battery cell that became popular during the nineteenth century was constructed in 1836 by the English chemist John Frederick Daniell. This cell used zinc and copper. The basic principle was that of Volta's battery pile, but each metal was surrounded by a solution of the metal ion, and the solutions were kept separate by a porous ceramic barrier. Each metal with its solution was a half-cell; a zinc half-cell and a copper half-cell made up one voltaic cell. This construction became the standard form of such cells, which exploit the spontaneous chemical reaction

to generate electrical energy.

Today many different kinds of batteries are in use. They include miniature button batteries for pocket calculators and watches, as well as larger batteries to power electric cars or to store the energy from the solar collectors of communications satellites. But all such batteries operate on the same general principles of Volta's pile or Daniell's cell. In this chapter, we will look at the general principles involved in setting up a chemical reaction as a battery. We will answer such questions as the following: What voltage can you expect from a particular battery? How can you relate the battery voltage to the equilibrium constant for the reaction?

## ▶ Half-Reactions

A voltaic cell employs a spontaneous oxidation–reduction reaction as a source of energy. It is constructed to separate the reaction physically into two half-reactions, one involving oxidation and the other reduction, with electrons moving from the oxidation half-reaction through the external circuit to the reduction half-reaction. ▶

### 19.1 Balancing Oxidation–Reduction Reactions in Acidic and Basic Solutions

In Chapter 4 (Section 4.6), we introduced the *half-reaction method* of balancing simple oxidation–reduction reactions. We now extend this method to reactions that occur in acidic or basic solutions. The steps used to balance these equations successfully are built upon those presented in Chapter 4. Keep in mind that oxidation–reduction reactions involve a transfer of electrons from one species to another. For example, in the reaction described in the chapter opener, zinc metal becomes zinc(II) ion: each zinc atom loses two electrons, and each copper(II) ion becomes copper metal (copper ion gains two electrons).

In this chapter, we will represent the hydronium ion,  $\text{H}_3\text{O}^+(aq)$ , by its simpler notation  $\text{H}^+(aq)$ , which chemists call the hydrogen ion. In the chapters that focused on acid–base reactions, we stressed proton transfer in solution, so we adopted the hydronium-ion notation. Here, we shift our focus to the electron-transfer aspect of certain reactions, so we adopt the simpler hydrogen-ion notation. Remember, however, that this is simply a notation change. It does not change the chemistry.

#### Skeleton Oxidation–Reduction Equations

To tackle more complex oxidation–reduction reactions in acidic and basic solutions, we need to review and discuss the essential information required to describe an

Figure 19.1 ▲

**Lemon battery** Zinc and copper strips in a lemon generate a voltage.

© Cengage Learning

You may wish to review Sections 4.5 and 4.6.

oxidation–reduction reaction, which is called a *skeleton equation*. To set up the skeleton equation and then balance it, you need answers to the following questions:

1. What species is being oxidized (or, what is the reducing agent)? What species is being reduced (or, what is the oxidizing agent)?
2. What species result from the oxidation and reduction?
3. Does the reaction occur in acidic or basic solution?

For example, iron(II) ion may be oxidized easily by a number of oxidizing agents to yield the iron(III) ion. Permanganate ion in acidic, aqueous solution is a strong oxidizing agent and can oxidize  $\text{Fe}^{2+}$  to  $\text{Fe}^{3+}$ . In the process of oxidizing the iron(II) ion, the permanganate ion ( $\text{MnO}_4^-$ ) is reduced to manganese(II) ion ( $\text{Mn}^{2+}$ ). We can express these facts in the following skeleton equation:

We have written oxidation numbers over the appropriate atoms. Note that the skeleton equation is not balanced. Nor is it complete; in an acidic, aqueous solution,  $\text{H}^+(\text{aq})$  and  $\text{H}_2\text{O}(\text{l})$  may be possible reactants or products in the equation. (If this were a basic solution,  $\text{OH}^-$  ion would replace the  $\text{H}^+$  ion.)

### Half-Reaction Method in Acidic and Basic Solutions

Although the preceding skeleton equation is not complete, it does give the essential information about the oxidation–reduction reaction. Moreover, given the skeleton equation, you can complete and balance the equation using the half-reaction method. Let us see how to do that. We first look at balancing oxidation–reduction equations in acidic solution. To balance such equations in basic solution requires additional steps.

#### Steps in Balancing Oxidation–Reduction Equations in Acidic Solution

**Step 1:** Assign oxidation numbers to each atom so you know what is oxidized and what is reduced.

**Step 2:** Split the skeleton equation into two half-reactions, proceeding as follows. Note the species containing the element that increases in oxidation number, and write those species to give the oxidation half-reaction. Similarly, note the species containing the element that decreases in oxidation number, and write the reduction half-reaction.

**Step 3:** Complete and balance each half-reaction.

- a Balance all atoms except O and H.
- b Balance O atoms by adding  $\text{H}_2\text{O}$ 's to one side of the equation.
- c Balance H atoms by adding  $\text{H}^+$  ions to one side of the equation.
- d Balance electric charge by adding electrons ( $\text{e}^-$ ) to the more positive side.

**Step 4:** Combine the two half-reactions to obtain the final balanced oxidation–reduction equation.

- a Multiply each half-reaction by a factor such that when the half-reactions are added, the electrons cancel. (Electrons cannot appear in the final equation.)
- b Simplify the balanced equation by canceling species that occur on both sides, and reduce the coefficients to the smallest whole numbers. Check that the equation is indeed balanced.

Let us see how we would apply this method to the skeleton equation we wrote for the oxidation of iron(II) ion by permanganate ion in acidic solution. We have already determined the elements that change oxidation number (**Step 1**). We now write the incomplete equation representing the oxidation half-reaction. Iron(II) is oxidized to iron(III) ion. Therefore, following **Step 2**, we write

Note that the equation is balanced in Fe as it stands (**Step 3a**). **Steps 3b and 3c** require that the half-reaction be balanced in O and H. However, since these atoms do not

appear in the half-reaction, we can ignore those steps. Then (Step 3d) you need to balance the half-reaction in electric charge. You do that by adding one electron to the more positive side.

Check that the half-reaction is balanced in Fe and in electric charge. Note that electrons are lost, as you expect for oxidation.

Now let us look at the reduction half-reaction. From the skeleton equation, you write the species containing the atom for which the oxidation number decreases (Step 2):

The equation is balanced in Mn as it stands (Step 3a). For Step 3b, you add four  $\text{H}_2\text{O}$ 's to the right side of the equation to balance the O atoms. (Water is present, since this is an aqueous solution.)

Step 3c says to balance the H atoms by adding  $\text{H}^+$  ions. (Hydrogen ions are present, since this is an acidic solution.) You add eight  $\text{H}^+$  ions to the left side of the equation.

Finally, you balance the half-reaction in electric charge by adding electrons to the more positive side of the equation (Step 3d). Note that the left side has a charge of  $(-1 + 8) = +7$ , whereas the right side has a charge of  $+2$ . So you add five electrons to the left side:

Check that this half-reaction is balanced in the different kinds of atoms and in electric charge. Note that electrons are gained, as you expect for reduction.

In Step 4a, you need to multiply each half-reaction by a factor such that when the two half-reactions are added, the electrons cancel. You multiply the oxidation half-reaction by 5 (the number of electrons in the reduction half-reaction) and multiply the reduction half-reaction by 1 (the number of electrons in the oxidation half-reaction). Then you add the two half-reactions:

After canceling electrons, the equation is in simplest form (Step 4b). The final balanced equation is

You can write this equation in terms of the hydronium-ion notation,  $\text{H}_3\text{O}^+(aq)$ , if you wish, by changing  $8\text{H}^+(aq)$  to  $8\text{H}_3\text{O}^+(aq)$  and adding  $8\text{H}_2\text{O}(l)$  to the other side of the equation to give a total of  $12\text{H}_2\text{O}(l)$ .

The following example further illustrates the half-reaction method.

### Example 19.1 Balancing Equations by the Half-Reaction Method (Acidic Solution)

#### Gaining Mastery Toolbox

##### Critical Concept 19.1

When an oxidation–reduction reaction occurs, there will be elements that change oxidation state. Oxidation numbers, introduced in Chapter 4, are used to

Zinc metal reacts with nitric acid,  $\text{HNO}_3$ , to produce a number of products, depending on how dilute the acid solution is. In a concentrated solution, zinc reduces nitrate ion to ammonium ion; zinc is oxidized to zinc ion,  $\text{Zn}^{2+}$ . Write the net ionic equation for this reaction.

(continued)

**Example 19.1** (continued)

track the oxidation states of elements involved in chemical reactions. For acidic solutions, there are excess protons ( $\text{H}^+$ ) available to balance the chemical equation.

**Solution Essentials:**

- Half-reaction-balancing method for acidic solutions
- Skeleton oxidation–reduction equations
- Balanced oxidation–reduction reaction
- Half-reaction
- Oxidation numbers
- Oxidation–reduction reaction

**Problem Strategy** From the word statement of the problem, you write the skeleton equation representing the essential features of the oxidation–reduction reaction. Then, assign oxidation numbers to the atoms (Step 1) and separate the skeleton equation into two incomplete half-reactions (Step 2). Now complete and balance each half-reaction (Step 3). (Balance the half-reaction in all elements except O and H; then balance O atoms, then H atoms, and finally electric charge.) In Step 4, you combine the half-reactions to eliminate electrons and simplify the result.

**Solution** Note that nitric acid is a strong acid, so it exists in solution as  $\text{H}^+$  and  $\text{NO}_3^-$  ions. For the skeleton equation, write just the  $\text{NO}_3^-$  ion, because you will be adding  $\text{H}^+$  later as needed to balance the equation. The skeleton equation, with oxidation numbers for those atoms that change values (following Step 1), is

Now you separate this equation into two incomplete half-reactions (Step 2). Note that zinc is oxidized (increases in oxidation number), and nitrogen is reduced (decreases in oxidation number). The two incomplete half-reactions are

The oxidation half-reaction is balanced in Zn, as it stands (Step 3a). There are no O or H atoms, so you can ignore Steps 3b and 3c. Following (Step 3d, you add electrons to the more positive side to balance the charge.

The reduction half-reaction is balanced in N (Step 3a) but is not complete in either O or H. Therefore, you add three  $\text{H}_2\text{O}$ 's to the right side to balance O atoms (Step 3b) and add ten  $\text{H}^+$  ions to the left side to balance the four H atoms in the  $\text{NH}_4^+$  ion and the six H atoms in the  $\text{H}_2\text{O}$ 's you just added (Step 3c).

Now, you add electrons to the more positive side to balance the charge.

Check that the half-reaction is balanced in charge, as well as in the different kinds of atoms.

Finally (Step 4a), you multiply the two half-reactions by factors so that when added, the electrons cancel. You multiply the oxidation half-reaction by 4 and the reduction half-reaction by 1:

The equation requires no further simplification beyond canceling electrons (Step 4b). The net ionic equation is

**Example 19.1** (continued)

**Answer Check** After you have completed the process for balancing this type of equation, you can perform a final check of your answer by making sure that you have both mass and charge balance.

**Exercise 19.1** Iodic acid,  $\text{HIO}_3$ , can be prepared by reacting iodine,  $\text{I}_2$ , with concentrated nitric acid. The skeleton equation is

Balance this equation.

See Problems 19.35 and 19.36.

To balance an oxidation–reduction equation in basic solution, you begin by balancing the equation *as if it were a reaction in acidic solution*. Then, you add the following steps. ►

### Additional Steps for Balancing Oxidation–Reduction Equations in Basic Solution

**Step 5:** Note the number of  $\text{H}^+$  ions in the equation. Add this number of  $\text{OH}^-$  ions to both sides of the equation.

**Step 6:** Simplify the equation by noting that  $\text{H}^+$  reacts with  $\text{OH}^-$  to give  $\text{H}_2\text{O}$ . Cancel any  $\text{H}_2\text{O}$ 's that occur on both sides of the equation and reduce the equation to simplest terms.

You can apply Steps 5 and 6 to the individual half-reactions, rather than to the overall equation. Although this is more work, it does yield the complete half-reactions, which can be useful in discussing batteries (later in this chapter).

The following example illustrates how to apply these rules.

**Example 19.2 Balancing Equations by the Half-Reaction Method (Basic Solution)****Gaining Mastery Toolbox****Critical Concept 19.2**

When an oxidation–reduction reaction occurs, there will be elements that change oxidation state. Oxidation numbers, introduced in Chapter 4, are used to track the oxidation states of elements involved in chemical reactions. For basic solutions, start the balancing process as if the solution is acidic. In the final balancing step, use excess hydroxide ions ( $\text{OH}^-$ ) to balance the chemical equation.

**Solution Essentials:**

- Half-reaction-balancing method for basic solutions
- Half-reaction-balancing method for acidic solutions
- Skeleton oxidation–reduction equations
- Balanced oxidation–reduction reaction
- Half-reaction
- Oxidation numbers
- Oxidation–reduction reaction

Permanganate ion oxidizes sulfite ion in basic solution according to the following skeleton equation:

Use the half-reaction method to complete and balance this equation.

**Problem Strategy** First complete and balance this equation as if it were in acid solution, as in the previous example. Then, following **Step 5**, add as many  $\text{OH}^-$  ions to both sides of the equation as there are  $\text{H}^+$  ions. After noting that each  $\text{H}^+$  ion reacts with an  $\text{OH}^-$  ion to give  $\text{H}_2\text{O}$ , simplify the equation (**Step 6**).

**Solution** After balancing the equation as if it were in acid solution, you obtain the following:

Following **Step 5**, you add  $2\text{OH}^-$  to both sides of the equation.

You replace  $2\text{H}^+ + 2\text{OH}^-$  by  $2\text{H}_2\text{O}$  on the left side, then cancel one of these with the  $\text{H}_2\text{O}$  on the right side. The balanced equation for the reaction in basic solution is

**Answer Check** Just as in balancing oxidation–reduction reactions in acidic solution, as a final check, be certain that the masses and charges balance in the equation.

**Exercise 19.2** Balance the following equation using the half-reaction method.

See Problems 19.36 and 19.37.

## ▶ Voltaic Cells

The next several sections describe battery cells, or voltaic cells (also called galvanic cells). These are a kind of electrochemical cell. An **electrochemical cell** is a system consisting of electrodes that dip into an electrolyte and in which a chemical reaction either uses or generates an electric current. A **voltaic**, or **galvanic**, cell is an electrochemical cell in which a spontaneous reaction generates an electric current. An **electrolytic cell** is an electrochemical cell in which an external energy source drives an otherwise nonspontaneous reaction. In the next sections, we will discuss the basic principles behind voltaic cells and then explore some of their commercial uses.

### 19.2 Construction of Voltaic Cells

A voltaic cell consists of two *half-cells* that are electrically connected. Each **half-cell** is the portion of an electrochemical cell in which a half-reaction takes place. A simple half-cell can be made from a metal strip that dips into a solution of its metal ion. An example is the zinc–zinc ion half-cell (often called simply a zinc electrode), which consists of a zinc metal strip dipping into a solution of a zinc salt. Another simple half-cell consists of a copper metal strip dipping into a solution of a copper salt (copper electrode).

In a voltaic cell, two half-cells are connected in such a way that electrons flow from one metal electrode to another through an external circuit, and ions flow from one half-cell to another through an internal cell connection. Figure 19.2 illustrates an atomic view of a voltaic cell consisting of a zinc electrode and a copper electrode. As long as there is an external circuit, electrons can flow through it from one electrode to another. Because zinc tends to lose electrons more readily than copper, zinc atoms on the surface of the zinc electrode lose electrons to produce zinc ions. These electrons flow through the external circuit to the copper electrode, where they react with the copper ions in that half-cell to deposit copper metal atoms. The net result is that zinc metal reacts with copper ions to produce zinc ions and copper metal, and an electric current flows through the external circuit.

The two half-cells must be connected internally to allow ions to flow between them. As zinc ions continue to be produced, the zinc ion solution begins to build

**Figure 19.2** ▲

**Atomic view of a voltaic cell** In the half-cell on the left, a zinc metal atom loses two electrons. These flow through the zinc electrode to the external circuit, then to the copper electrode in the half-cell on the right. Negative charge on the copper electrode (from the electrons) attracts a copper ion, which reacts with the electrons on the electrode to form a copper metal atom. The internal connection, discussed later in the text, allows ions to flow between the two half-cells; it is required to maintain charge balance.

up a positive charge. Similarly, as copper ions plate out as copper metal, the solution builds up a negative charge. The half-cell reactions will stop unless positive ions can move from the zinc half-cell to the copper half-cell, and negative ions from the copper half-cell can move to the zinc half-cell. It is necessary that these ion flows occur without mixing of the zinc ion and copper ion solutions. If copper ion were to come in contact with the zinc metal, for example, direct reaction would occur without an electric current being generated. The voltage would drop, and the battery would run down quickly.

Figure 19.3a shows the two half-cells of a voltaic cell connected by a salt bridge. A **salt bridge** is a tube of an electrolyte in a gel that is connected to the two half-cells of a voltaic cell; the salt bridge allows the flow of ions but prevents the mixing of the different solutions that would allow direct reaction of the cell reactants. In Figure 19.3b, the half-cells are connected externally so that an electric current flows. Figure 19.3c shows an actual setup of the zinc–copper cell.

The two half-cell reactions, as noted earlier, are

Figure 19.3 ◀

A zinc–copper voltaic cell

The first half-reaction, in which a species loses electrons, is the oxidation half-reaction. *The electrode at which oxidation occurs* is called the **anode**. The second half-reaction, in which a species gains electrons, is the reduction half-reaction. *The electrode at which reduction occurs* is called the **cathode**. These definitions of anode and cathode hold for all electrochemical cells, including electrolytic cells.

Note that the sum of the two half-reactions

is *the net reaction that occurs in the voltaic cell*; it is called the **cell reaction**.

Once you know which electrode is the anode and which is the cathode, you can determine the direction of electron flow in the external portion of the circuit. Electrons are given up by the anode (from the oxidation half-reaction) and thus flow from it, whereas electrons are used up by the cathode (by the reduction half-reaction) and so flow into this electrode. The anode in a voltaic cell has a negative sign, because electrons flow from it. The cathode in a voltaic cell has a positive sign. Look again at Figure 19.3b and note the labeling of the electrodes as anode and cathode; also note the direction of electron flow in the external circuit and the signs of the electrodes. Note too the migration of ions in the solutions. The following example further illustrates these points about a voltaic cell.

### Example 19.3 Sketching and Labeling a Voltaic Cell

#### Gaining Mastery Toolbox

##### Critical Concept 19.3

An electrochemical cell is composed of two half-cells. Each half-reaction is contained in a separate half-cell. Electrons flow from the anode (oxidation) to the cathode (reduction).

##### Solution Essentials:

- Anode and cathode
- Salt bridge
- Half-cell
- Voltaic cell
- Electrochemical cell
- Balanced oxidation–reduction reaction
- Half-reaction
- Oxidation–reduction reaction

A voltaic cell is constructed from a half-cell in which a cadmium rod dips into a solution of cadmium nitrate,  $\text{Cd}(\text{NO}_3)_2$ , and another half-cell in which a silver rod dips into a solution of silver nitrate,  $\text{AgNO}_3$ . The two half-cells are connected by a salt bridge. Silver ion is reduced during operation of the voltaic cell. Draw a sketch of the cell. Label the anode and cathode, showing the corresponding half-reactions at these electrodes. Indicate the electron flow in the external circuit (with a lightbulb), the signs of the electrodes, and the direction of cation migration in the half-cells.

**Problem Strategy** The problem states that silver ion is reduced during the cell operation, so we know that silver is the cathode. If silver is the cathode, then cadmium must be the anode. With this information we can then write the half-reactions. The half-reactions provide all of the information we need to draw a complete sketch of the cell.

**Solution** Because silver ion is reduced at the silver electrode, the silver electrode is the cathode. The half-reaction is

The cadmium electrode must be the anode (the electrode at which oxidation occurs); the half-reaction is

Now that you have labeled the electrodes, you can see that the electron flow in the external circuit is from the cadmium electrode (anode) to the silver electrode (cathode). Positive ions will flow in the solution portion of the circuit opposite to the direction of the electrons. **The sketch for this cell, including the labeling, is given in Figure 19.4.**

(continued)

**Example 19.3** (continued)**Figure 19.4** ▲

**Cell described in the example** A voltaic cell consisting of cadmium and silver electrodes.

**Answer Check** Make sure that the direction of electron flow is consistent with the half-reactions; the electrons always flow *from* the material undergoing oxidation.

**Exercise 19.3** A voltaic cell consists of a silver–silver ion half-cell and a nickel–nickel(II) ion half-cell. Silver ion is reduced during operation of the cell. Sketch the cell, labeling the anode and cathode and indicating the corresponding electrode reactions. Show the direction of electron flow in the external circuit and the direction of cation movement in the half-cells.

See Problems 19.43 and 19.44.

**✓ CONCEPT CHECK 19.1**

If you were to construct a wet cell and decided to replace the salt bridge with a piece of copper wire, would the cell produce a sustainable current? Explain your answer.

## 19.3 Notation for Voltaic Cells

It is convenient to have a shorthand way of designating particular voltaic cells. The cell described earlier, consisting of a zinc metal–zinc ion half-cell and a copper metal–copper ion half-cell, is written

In this notation, the anode, or oxidation half-cell, is always written on the left; the cathode, or reduction half-cell, is written on the right. The two electrodes are electrically connected by means of a salt bridge, denoted by two vertical bars.

**Figure 19.5** ▲

**A hydrogen electrode** Hydrogen gas bubbles over a platinum surface, where the half-reaction  $2\text{H}^+(aq) + 2e^- \rightleftharpoons \text{H}_2(g)$  occurs.

The cell terminals are at the extreme ends in this cell notation, and a single vertical bar indicates a phase boundary—say, between a solid terminal and the electrode solution. For the anode of the same cell, you have

When the half-reaction involves a gas, an inert material such as platinum serves as a terminal and as an electrode surface on which the half-reaction occurs. The platinum catalyzes the half-reaction but otherwise is not involved in it. Figure 19.5 shows a hydrogen electrode; hydrogen bubbles over a platinum plate that is immersed in an acidic solution. The cathode half-reaction is

The notation for the hydrogen electrode, written as a cathode, is

To write such an electrode as an anode, you simply reverse the notation:

Here are several additional examples of this notation for electrodes (written as cathodes). A comma separates ions present in the same solution. We will write the cathode with oxidized species before reduced species, in the same order as in the half-reaction.

<i>Cathode</i>	<i>Cathode Reaction</i>
$\text{Cl}_2(g)   \text{Cl}^-(aq)   \text{Pt}$	$\text{Cl}_2(g) + 2e^- \rightleftharpoons 2\text{Cl}^-(aq)$
$\text{Fe}^{3+}(aq), \text{Fe}^{2+}(aq)   \text{Pt}$	$\text{Fe}^{3+}(aq) + e^- \rightleftharpoons \text{Fe}^{2+}(aq)$
$\text{Cd}^{2+}(aq)   \text{Cd}(s)$	$\text{Cd}^{2+}(aq) + 2e^- \rightleftharpoons \text{Cd}(s)$

**Exercise 19.4** Write the notation for a cell in which the electrode reactions are

See Problems  
19.49 and 19.50.

You can write the overall cell reaction from the cell notation by first writing the appropriate half-cell reactions, multiplying as necessary, and then summing so that the electrons cancel. Example 19.4 shows how this is done.

### Example 19.4 Writing the Cell Reaction from the Cell Notation

#### Gaining Mastery Toolbox

##### Critical Concept 19.4

Cell notation fully describes the half-reactions of a voltaic cell. This notation can include the phases of the substances, ion concentrations, and gas pressures. The anode half-cell reaction is always represented on the left.

##### Solution Essentials:

- Cell notation
- Anode and cathode
- Salt bridge

a. Write the cell reaction for the voltaic cell

b. Write the cell reaction for the voltaic cell

**Problem Strategy** The cell notation gives the species involved in each half-reaction. Complete and balance each half-reaction, and then multiply by factors so that when you add the half-reactions, the electrons cancel. The result is the cell reaction.

(continued)

**Example 19.4** (continued)

- Half-cell
- Voltaic cell
- Electrochemical cell
- Balanced oxidation–reduction reaction
- Half-reaction
- Oxidation–reduction reaction

**Solution**

a. The half-cell reactions are

Multiplying the anode reaction by 2 and then summing the half-cell reactions gives

b. The half-cell reactions are

and the cell reaction is

**Answer Check** Always make sure that you multiplied the half-reactions by the correct coefficients to ensure that the electrons cancel.

**Exercise 19.5** Give the overall cell reaction for the voltaic cell

See Problems 19.53 and 19.54.

To fully specify a voltaic cell, it is necessary to give the concentrations of solutions or ions and the pressure of gases. In the cell notation, these are written within parentheses for each species. For example,

**19.4 Cell Potential**

Work is needed to move electrons in a wire or to move ions through a solution to an electrode. The situation is analogous to pumping water from one point to another. Work must be expended to pump the water. The analogy may be extended. Water moves from a point at high pressure to a point at low pressure. Thus, a pressure difference is required. The work expended in moving water through a pipe depends on the volume of water and the pressure difference. The situation with electricity is similar. An electric charge moves from a point at high electric potential (high electrical pressure) to a point at low electric potential (low electrical pressure). The work needed to move an electric charge through a conductor depends on the total charge moved and the potential difference. **Potential difference** is the difference in electric potential (electrical pressure) between two points. You measure this quantity in volts. The **volt, V**, is the SI unit of potential difference. The electrical work expended in moving a charge through a conductor is

$$\text{Electrical work} = \text{charge} \times \text{potential difference}$$

Corresponding SI units for the terms in this equation are

$$\text{Joules} = \text{coulombs} \times \text{volts}$$

The **Faraday constant,  $F$** , is the magnitude of charge on one mole of electrons; it equals  $9.6485 \times 10^4$  C per mole of electrons (96,485 C/mol  $e^-$ ). The *faraday* is a unit of charge equal to  $9.6485 \times 10^4$  C. In moving this quantity of charge (1 faraday of charge) from one electrode to another, the numerical value of the work done by a voltaic cell is the product of the faraday constant  $F$  times the potential

Figure 19.6 ▲

**A digital voltmeter** A digital voltmeter draws negligible current, so it can be used to measure cell potential.

difference between the electrodes. The work  $w$  is the negative of this, because the voltaic cell loses energy as it does work on the surroundings.

$$w = -F \times \text{potential difference}$$

In the normal operation of a voltaic cell, the potential difference (voltage) across the electrodes is less than the maximum possible voltage of the cell. One reason for this is that it takes energy or work to drive a current through the cell itself. The decrease in cell voltage as current is drawn reflects this energy expenditure within the cell; and the greater the current, the lower the voltage. Thus, the cell voltage has its maximum value only when no current flows. The situation is analogous to measuring the difference between the pressure of water in a faucet and that of the outside atmosphere. You expect this difference to be higher if you measure it by a device that does not require you to run water from the faucet. When you do run water, the pressure difference drops.

The maximum potential difference between the electrodes of a voltaic cell is referred to as the **cell potential** or **electromotive force (emf)** of the cell, or  $E_{\text{cell}}$ . It can be measured by an electronic digital voltmeter (Figure 19.6).

You can also determine which electrode of a cell is the anode and which is the cathode from this measurement. The digital voltmeter gives the reading with a sign attached, from which you can deduce the sign, or polarity, of each electrode. The anode of a voltaic cell has negative polarity, and the cathode has positive polarity.

We can now write an expression for the maximum work obtainable from a voltaic cell. Let  $n$  be the number of moles of electrons transferred in the overall cell equation. The maximum electrical work of a voltaic cell for molar amounts of reactants (according to the cell equation *as written*) is

$$w_{\text{max}} = -nFE_{\text{cell}}$$

Here  $E_{\text{cell}}$  is the cell potential, and  $F$  is the Faraday constant,  $9.6485 \times 10^4 \text{ C/mol e}^-$ .

### Example 19.5 Calculating the Quantity of Work from a Given Amount of Cell Reactant

#### Gaining Mastery Toolbox

##### Critical Concept 19.5

The equation for the maximum electrical work ( $w_{\text{max}} = -nFE_{\text{cell}}$ ) is only for the molar amounts of reactants in the balanced chemical equation. Balancing the electrochemical equation will provide the values of  $n$  and  $E_{\text{cell}}$  for the equation and the subsequent calculation of  $w_{\text{max}}$ . If the amount of reactants is *not* the same as that in the balanced electrochemical equation, then the maximum work must be calculated using the quantities of reactant consumed.

##### Solution Essentials:

- Maximum electrical work of voltaic cell ( $w_{\text{max}} = -nFE_{\text{cell}}$ )
- Cell potential
- Balanced oxidation–reduction reaction
- Half-reaction

The cell potential of a particular voltaic cell with the cell reaction

is 0.650 V. Calculate the maximum electrical work of this cell when 0.500 g  $\text{H}_2$  is consumed.

**Problem Strategy** We can determine the maximum work of a cell by using the formula  $w_{\text{max}} = -nFE_{\text{cell}}$ , where  $E_{\text{cell}}$  is given in the problem,  $F$  is the Faraday constant, and  $n$  is the number of moles of electrons transferred in the overall cell equation. To get  $n$ , you split the cell reaction into half-reactions, multiplying each by a factor so that when added together, they give the cell reaction. Then  $n$  equals the number of moles of electrons in either half-reaction.

**Solution** The half-reactions are

$n$  equals 2, and the maximum work for the reaction as written is

$$\begin{aligned} w_{\text{max}} &= -nFE_{\text{cell}} = -2 \text{ mol e}^- \times 96,485 \text{ C/mol e}^- \times 0.650 \text{ V} \\ &= -1.25 \times 10^5 \text{ V} \cdot \text{C} \\ &= -1.25 \times 10^5 \text{ J} \end{aligned}$$

(continued)

**Example 19.5** (continued)

(Remember that a joule is equal to a volt-coulomb. Also, note that the negative sign means work is done by the cell—that is, energy is lost by the cell.) For 0.500 g H<sub>2</sub>, the maximum work is

$$0.500 \text{ g H}_2 \times \frac{1 \text{ mol H}_2}{2.02 \text{ g H}_2} \times \frac{-1.25 \times 10^5 \text{ J}}{1 \text{ mol H}_2} = -3.09 \times 10^4 \text{ J}$$

Note that the conversion factor  $-1.25 \times 10^5 \text{ J/1 mol H}_2$  is determined by the chemical equation as written. In the equation, 1 mol H<sub>2</sub> reacts, and the maximum work produced is  $-1.25 \times 10^5 \text{ J}$ .

**Answer Check** The maximum work per mole should be in the range of values expected for  $\Delta G$ , which is on the order of tens to hundreds of kilojoules per mole, as it is here. You should be suspicious of any values that you obtain that lie outside this range.

**Exercise 19.6** What is the maximum electrical work that can be obtained from 6.54 g of zinc metal that reacts in a Daniell cell, described in the chapter opening, whose cell potential is 1.10 V? (Assume that there is an excess of copper ions in solution.) The overall cell reaction is

See Problems 19.57, 19.58, 19.59, and 19.60.

## 19.5 Standard Cell Potentials and Standard Electrode Potentials

A cell potential is a measure of the driving force of the cell reaction. This reaction occurs in the cell as separate half-reactions: an oxidation half-reaction and a reduction half-reaction. The general forms of these half-reactions are

You can imagine that the cell potential is composed of a contribution from the anode (whose value depends on the ability of the oxidation half-reaction to lose electrons) and a contribution from the cathode (whose value depends on the ability of the reduction half-reaction to gain electrons). We call these contributions the *oxidation potential* and the *reduction potential*, respectively. Then

$$E_{\text{cell}} = \text{oxidation potential} + \text{reduction potential}$$

A reduction potential is a measure of the tendency for an oxidized species to gain electrons in the reduction half-reaction (in other words, a measure of the ability of the species to act as an oxidizing agent). If you can construct a table of reduction potentials, you will have a list of strengths of oxidizing agents, in addition to having a way of calculating cell potentials.

You can look at an oxidation half-reaction as the reverse of a corresponding reduction half-reaction. The oxidation potential for an oxidation half-reaction equals the negative of the reduction potential for the reverse half-reaction (which is a reduction).

$$\text{Oxidation potential for a half-reaction} = -\text{reduction potential for the reverse half-reaction}$$

This means that in practice you need to tabulate only oxidation potentials or reduction potentials. The choice, by convention, is to tabulate reduction potentials. We call these *electrode potentials*, and we denote them by the symbol  $E$  (without the subscript cell, as in  $E_{\text{cell}}$ ).

Consider the zinc–copper cell described earlier.

The half-reactions are

The first half-reaction is an oxidation. If you write  $E_{\text{Zn}}$  for the electrode potential corresponding to the reduction half-reaction  $\text{Zn}^{2+}(aq) + 2e^{-} \longrightarrow \text{Zn}(s)$ , then  $-E_{\text{Zn}}$  is the potential for the oxidation half-reaction  $\text{Zn}(s) \longrightarrow \text{Zn}^{2+}(aq) + 2e^{-}$ . The copper half-reaction is a reduction. Write  $E_{\text{Cu}}$  for the electrode potential.

The cell potential is the sum of the potentials for the reduction and oxidation half-reactions. For the cell we have been describing, the cell potential is the sum of the reduction potential (electrode potential) for the copper half-cell and the oxidation potential (negative of the electrode potential) for the zinc half-cell.

$$E_{\text{cell}} = E_{\text{Cu}} + (-E_{\text{Zn}}) = E_{\text{Cu}} - E_{\text{Zn}}$$

Note that the cell potential equals the difference between the two electrode potentials. You can think of the electrode potential as the electric potential on the electrode, and you obtain the cell potential as a potential difference in which you subtract the anode potential from the cathode potential.

$$E_{\text{cell}} = E_{\text{cathode}} - E_{\text{anode}}$$

The electrode potential is an *intensive property*. This means that its value is independent of the amount of species in the reaction. Thus, the electrode potential for the half-reaction

is the same as for

### Tabulating Standard Electrode Potentials

The cell potential of a voltaic cell depends on the concentrations of substances and the temperature of the cell. For purposes of tabulating electrochemical data, it is usual to choose thermodynamic standard-state conditions for voltaic cells. The **standard cell potential**,  $E_{\text{cell}}^{\circ}$ , is the *emf of a voltaic cell operating under standard-state conditions (solute concentrations are each 1 M, gas pressures are each 1 atm, and the temperature has a specified value—usually 25°C)*. Note the superscript degree sign ( $^{\circ}$ ), which signifies standard-state conditions. ◀

If you can derive a table of electrode potentials, you can calculate cell potentials from them. This provides a great advantage over tabulating cell potentials. From a small table of electrode potentials, you can obtain all the cell potentials you could construct from pairs of electrodes. For instance, a table of 40 electrode potentials would give the cell potentials of nearly 800 voltaic cells.

However, it is not possible to measure the potential of a single electrode; only the cell potentials of cells can be measured. What you can do is measure the cell potentials of cells constructed from various electrodes connected in turn to one particular electrode, which you choose as a reference. You arbitrarily assign this reference electrode a potential equal to zero and obtain the potentials for the other electrodes by measuring the cell potentials. By convention, the reference chosen for comparing electrode potentials is the *standard hydrogen electrode*, and it is assigned a potential of 0.00 V. This is an electrode like that pictured earlier in Figure 19.5 operating under standard-state conditions.

The **standard electrode potential**,  $E^{\circ}$ , is the *electrode potential when the concentrations of solutes are 1 M, the gas pressures are 1 atm, and the temperature has a*

To be precise, the standard-state conditions are those in which the activities (ideal concentrations) of solutes and gases equal 1. This is equivalent to 1 M only for ideal solutions. Because of the strong attractions between ions, substantial deviations from ideal conditions exist in electrolyte solutions, except when very dilute. We will ignore these deviations here.

*specified value (usually 25°C)*. The superscript degree sign ( $^\circ$ ) signifies standard-state conditions.

To understand how standard electrode potentials are obtained, look at how you would find the standard electrode potential,  $E^\circ$ , for the zinc electrode. You connect a standard zinc electrode to a standard hydrogen electrode. When you measure the cell potential with a voltmeter, you obtain 0.76 V, with the zinc electrode acting as the anode.

Now write the cell potential in terms of the electrode potentials. The cell is

and the half-reactions with corresponding half-cell potentials (oxidation or reduction potentials) are

The cell potential is the sum of the half-cell potentials.

$$E_{\text{cell}} = E_{\text{H}_2}^\circ + (-E_{\text{Zn}}^\circ)$$

Substitute 0.76 V for the cell potential and 0.00 V for the standard hydrogen electrode potential. This gives  $E_{\text{Zn}}^\circ = -0.76$  V.

Proceeding in this way, you can obtain the electrode potential for a series of half-cell reactions. Table 19.1 lists standard electrode potentials for selected half-cells at 25°C.

### Strengths of Oxidizing and Reducing Agents

Standard electrode potentials are useful in determining the strengths of oxidizing and reducing agents under standard-state conditions. Because electrode potentials are reduction potentials, those reduction half-reactions in Table 19.1 with the larger (that is, more positive) electrode potentials have the greater tendency to go left to right as written. A reduction half-reaction has the general form

The oxidized species acts as an oxidizing agent. Consequently, *the strongest oxidizing agents in a table of standard electrode potentials are the oxidized species corresponding to half-reactions with the largest (most positive)  $E^\circ$  values.*

Those reduction half-reactions with lower (that is, more negative) electrode potentials have a greater tendency to go right to left. That is,

The reduced species acts as a reducing agent. Consequently, *the strongest reducing agents in a table of standard electrode potentials are the reduced species corresponding to half-reactions with the smallest (most negative)  $E^\circ$  values.*

The first two and the last two entries in Table 19.1 are as follows:

The strongest oxidizing agents are the species on the left side in the last two entries in the table (given here in red). The strongest reducing agents are the species on the right side in the first two entries in the table (given here in blue).

**Table 19.1** Standard Electrode (Reduction) Potentials in Aqueous Solution at 25°C\*

Cathode (Reduction) Half-Reaction	Standard Potential, $E^\circ$ (V)

\*See Appendix I for a more extensive table.

**Example 19.6 Determining the Relative Strengths of Oxidizing and Reducing Agents****Gaining Mastery Toolbox****Critical Concept 19.6**

The strongest oxidizing agents are *reactants* at the bottom of the table of standard electrode potentials (Table 19.1), while the strongest reducing agents are *products* at the top of the table. A strong oxidizing agent is favored to gain electrons during an electrochemical reaction. A strong reducing agent is favored to lose electrons during an electrochemical reaction.

**Solution Essentials:**

- Table of Standard Electrode (Reduction) Potentials (Table 19.1)
- Standard electrode potential
- Half-reaction
- Oxidation–reduction reaction
- Oxidizing agent
- Reducing agent

- a. Order the following oxidizing agents by increasing strength under standard-state conditions:  $\text{Cl}_2(g)$ ,  $\text{H}_2\text{O}_2(aq)$ ,  $\text{Fe}^{3+}(aq)$ .
- b. Order the following reducing agents by increasing strength under standard-state conditions:  $\text{H}_2(g)$ ,  $\text{Al}(s)$ ,  $\text{Cu}(s)$ .

**Problem Strategy**

- a. Read down the table of electrode potentials, picking out the reduction half-reactions in which the species of interest occur as reactants. The order from *top to bottom* in which these species occur in the table is the order of increasing oxidizing power.
- b. Read down the table of electrode potentials, picking out the reduction half-reactions in which the species of interest occur as products. The order from *bottom to top* in which these species occur in the table is the order of increasing reducing strength.

**Solution**

- a. The half-reactions and corresponding electrode potentials are as follows:

The order by increasing oxidizing strength is  $\text{Fe}^{3+}(aq)$ ,  $\text{Cl}_2(g)$ ,  $\text{H}_2\text{O}_2(aq)$ .

- b. The half-reactions and corresponding electrode potentials are

The order by increasing reducing strength is  $\text{Cu}(s)$ ,  $\text{H}_2(g)$ ,  $\text{Al}(s)$ .

**Answer Check** To consistently get this type of problem right, make certain that you understand that the strongest oxidizing agents are those species that are most likely to undergo reduction, and the strongest reducing agents are the least likely to undergo reduction.

**Exercise 19.7** Which is the stronger oxidizing agent,  $\text{NO}_3^-(aq)$  in acidic solution (to  $\text{NO}$ ) or  $\text{Ag}^+(aq)$ ?

See Problems 19.61, 19.62, 19.63, and 19.64.

You can use a table of electrode potentials to predict the direction of spontaneity of an oxidation–reduction reaction. You need note only the relative strengths of the oxidizing agents on the left and right sides of the equation. The stronger oxidizing agent will be on the reactant side when the equation is written as a spontaneous reaction. (Alternatively, you can look at the reducing agents; the stronger reducing agent will be on the reactant side of the spontaneous reaction.)

**Example 19.7 Determining the Direction of Spontaneity from Electrode Potentials****Gaining Mastery Toolbox****Critical Concept 19.7**

Spontaneous reactions have the species undergoing reduction with the more positive standard electron potential. Only when the reaction is written in such a way that the oxidizing agent (the species undergoing reduction) is strong enough to remove electrons from the reducing agent (the species undergoing oxidation) will a spontaneous reaction occur.

Consider the reaction

Does the reaction go spontaneously in the direction indicated, under standard conditions?

**Problem Strategy** Find the oxidizing agents in the equation; one is on the left side and the other on the right side. Locate these oxidizing agents in a table of electrode potentials. (The oxidizing agent is on the left side of the reduction half-reaction.) The stronger oxidizing agent is the one involved in the half-reaction with the more positive standard electrode potential.

(continued)

**Example 19.7** (continued)**Solution Essentials:**

- Table of Standard Electrode (Reduction) Potentials (Table 19.1)
- Standard electrode potential
- Spontaneous reaction
- Half-reaction
- Oxidation–reduction reaction
- Oxidizing agent
- Reducing Agent

**Solution** In this reaction,  $\text{Zn}^{2+}$  is the oxidizing agent on the left side;  $\text{Fe}^{3+}$  is the oxidizing agent on the right side. The corresponding standard electrode potentials are

The stronger oxidizing agent is the one involved in the half-reaction with the more positive standard electrode potential, so  $\text{Fe}^{3+}$  is the stronger oxidizing agent. The reaction is **nonspontaneous** as written.

**Answer Check** When writing the half-reactions for comparison, make sure that you have noted the correct sign of  $E^{\circ}$  for each reaction.

**Exercise 19.8** Does the following reaction occur spontaneously in the direction indicated, under standard conditions?

See Problems 19.65 and 19.66.

**Calculating Cell Potentials**

When calculating cell potential values, chemists employ two approaches, both of which rely on using standard reduction potential values. One approach requires that you combine half-reactions and their standard potential values (reduction and oxidation); the other involves using an equation to calculate the difference between standard reduction potentials. The advantage of the first approach is that while determining a cell potential value, you will develop a complete understanding of the half-reactions that are taking place in the cell, identification of the species that are undergoing oxidation and reduction, as well as the number of electrons involved in the balanced oxidation–reduction reaction. The second approach involves determination of the anode and cathode in the reaction and using an equation with the appropriate reduction potentials. The advantage of this approach is that you can quickly calculate the cell potential from tabulated standard reduction potential values and that you are calculating the cell potential by difference.

**Calculating Cell Potentials by Addition of Half-Reactions and Standard Potentials** Consider a voltaic cell constructed from a cadmium electrode and a silver electrode having the following reduction half-reactions and corresponding standard electrode potentials (reduction potentials):

You will need to reverse one of these half-reactions to obtain the oxidation part of the cell reaction. The cell reaction is spontaneous, with the stronger reducing agent on the left. This will be Cd, because it is the reactant in the half-reaction with the more negative electrode potential. Therefore, you reverse the first half-reaction, as well as the sign of the half-cell potential (to obtain the oxidation potential, which equals  $-E_{\text{Cd}}^{\circ}$ ).

To obtain the cell reaction, you must multiply the half-reactions by factors so that when the half-reactions are added together, the electrons cancel. This does not

affect the half-cell potentials, which do not depend on amount of substance. You multiply the second half-reaction by 2 and then add.

The cell potential,  $E_{\text{cell}}^{\circ}$ , is 1.20 V. The cell diagram is

Suppose that at the beginning of this problem, you had mistakenly reversed the silver half-reaction, instead of correctly reversing the cadmium half-reaction. Then your work would have looked like the following:

The corresponding cell notation would have been

Everything is simply the reverse of the correct result. At this point, you realize your mistake, because the cell potential is found to be negative. A negative potential merely indicates that the cell reaction is nonspontaneous as written. To obtain the spontaneous reaction and a positive cell potential, you simply reverse both half-reactions and corresponding half-cell potentials. (You would also reverse the cell notation.) This changes the sign of the cell potential.

**Calculation of Cell Potentials Using Standard Reduction Potentials** Note that in the case of the cadmium–silver cell above, the cell potential equals the standard electrode potential of the cathode minus the standard electrode potential of the anode. Thus, alternatively, you can calculate any cell potential using the equation

$$E_{\text{cell}}^{\circ} = E_{\text{cathode}}^{\circ} - E_{\text{anode}}^{\circ}$$

Applying this equation to our example, you obtain

$$E_{\text{cell}}^{\circ} = E_{\text{Ag}}^{\circ} - E_{\text{Cd}}^{\circ} = 0.80 \text{ V} - (-0.40 \text{ V}) = 1.20 \text{ V}$$

### Example 19.8 Calculating the Cell Potential from Standard Potentials

#### Gaining Mastery Toolbox

##### Critical Concept 19.8

A voltaic cell always has a positive standard cell potential. When employing the addition of half-reaction approach, the half-reactions must be combined in such a way that the sum of the half-cell potentials add up to a voltage greater than zero. Direct calculation of the standard cell potential can be accomplished by using the equation

$$E_{\text{cell}}^{\circ} = E_{\text{cathode}}^{\circ} - E_{\text{anode}}^{\circ}$$

##### Solution Essentials:

- Standard cell potential ( $E_{\text{cell}}^{\circ}$ )
- Direct calculation of standard cell potential ( $E_{\text{cell}}^{\circ} = E_{\text{cathode}}^{\circ} - E_{\text{anode}}^{\circ}$ )
- Table of Standard Electrode (Reduction) Potentials (Table 19.1)

Calculate the standard cell potential of the following voltaic cell at 25°C using standard electrode potentials.

What is the cell reaction?

**Problem Strategy** From a table of electrode potentials, write the two reduction half-reactions and standard electrode potentials for the cell. The cell notation assumes that the anode (the oxidation half-cell) is on the left. Change the direction of this half-reaction and the sign of its electrode potential. (Assuming that the cell notation was written correctly, you change the direction of the half-reaction corresponding to the smaller, or more negative, electrode potential.) Multiply the half-reactions (but not the electrode potentials) by factors so that when the half-reactions are added, the electrons cancel. The sum of the half-reactions is the cell reaction. Add the electrode potentials to get the cell potential.

An alternative strategy is to apply the equation

$$E_{\text{cell}}^{\circ} = E_{\text{cathode}}^{\circ} - E_{\text{anode}}^{\circ}$$

(continued)

**Example 19.8** (continued)

- Cell notation
- Voltaic cell
- Anode and cathode
- Balanced oxidation–reduction reaction
- Half-reaction

**Solution (Both Approaches)** The reduction half-reactions and standard electrode potentials are

You reverse the first half-reaction and its half-cell potential to obtain

You obtain the cell potential by adding the half-cell potentials. Because you also want the cell reaction, you multiply the first half-reaction by 2 and the second half-reaction by 3, so that when the half-reactions are added, the electrons cancel. The addition of half-reactions is displayed below. The cell potential is **1.25 V**.

Alternatively, you can calculate the cell potential from the formula

$$E_{\text{cell}}^{\circ} = E_{\text{cathode}}^{\circ} - E_{\text{anode}}^{\circ}$$

to obtain

$$\begin{aligned} E_{\text{cell}}^{\circ} &= E_{\text{Fe}}^{\circ} - E_{\text{Al}}^{\circ} \\ &= -0.41 \text{ V} - (-1.66 \text{ V}) \\ &= 1.25 \text{ V} \end{aligned}$$

**Answer Check** If the problem states that the cell is voltaic, the cell potential should always be positive as it is here. If you calculate a negative cell potential for a voltaic cell, it is likely that you reversed the half-reactions or mislabeled the anode and cathode.

**Exercise 19.9** Using standard electrode potentials, calculate  $E_{\text{cell}}^{\circ}$  at 25°C for the following cell.

See Problems 19.69 and 19.70.

**CONCEPT CHECK 19.2**

Let us define the reduction of  $\text{I}_2$  to  $\text{I}^{-}$  ions,  $\text{I}_2(\text{s}) + 2\text{e}^{-} \longrightarrow 2\text{I}^{-}(\text{aq})$ , as the standard reduction reaction with  $E^{\circ} = 0.00 \text{ V}$ . We then construct a new standard reduction table based on this definition.

- What would be the new standard reduction potential of  $\text{H}^{+}$ ?
- Would using a new standard reduction table change the *measured* value of a freshly prepared voltaic cell made from Cu and Zn? (Assume you have the appropriate solutions and equipment to construct the cell.)
- Would the calculated voltage for the cell in part b be different if you were using the values presented in Table 19.1? Do the calculations to justify your answer.

## 19.6 Equilibrium Constants from Cell Potentials

Some of the most important results of electrochemistry are the relationships among cell potential, free-energy change, and equilibrium constant. Recall that the free-energy change  $\Delta G$  for a reaction equals the maximum useful work of the reaction (Section 18.5).

$$\Delta G = w_{\max}$$

For a voltaic cell, this work is the electrical work,  $-nFE_{\text{cell}}$  (where  $n$  is the number of moles of electrons transferred in a reaction), so when the reactants and products are in their standard states, you have

$$\Delta G^\circ = -nFE_{\text{cell}}^\circ$$

With this equation, cell potential measurements become an important source of thermodynamic information. Alternatively, thermodynamic data can be used to calculate cell potentials. These calculations are shown in the following examples.

### Example 19.9 Calculating the Free-Energy Change from Electrode Potentials

#### Gaining Mastery Toolbox

##### Critical Concept 19.9

A spontaneous chemical reaction will have a standard cell potential ( $E_{\text{cell}}^\circ$ ) that is a positive number (voltaic cell). The standard cell potential,  $E_{\text{cell}}^\circ$ , is related to the standard free-energy change,  $\Delta G^\circ$ , of a chemical reaction by the equation  $\Delta G^\circ = -nFE_{\text{cell}}^\circ$ .

##### Solution Essentials:

- Free-energy change of electrochemical reaction ( $\Delta G^\circ = -nFE_{\text{cell}}^\circ$ )
- Direct calculation of standard cell potential ( $E_{\text{cell}}^\circ = E_{\text{cathode}}^\circ - E_{\text{anode}}^\circ$ )
- Table of Standard Electrode (Reduction) Potentials (Table 19.1)
- Voltaic cell
- Standard free energy ( $\Delta G^\circ$ )
- Balanced oxidation–reduction reaction
- Half-reaction

Using standard electrode potentials, calculate the standard free-energy change at 25°C for the reaction

**Problem Strategy** Substitute into  $\Delta G^\circ = -nFE_{\text{cell}}^\circ$ . Use a table of standard electrode potentials to obtain  $E_{\text{cell}}^\circ$ . The cell reaction equals the sum of the half-reactions after they have been multiplied by factors so that the electrons cancel in the summation. Note that  $n$  is the number of moles of electrons involved in each half-reaction.

**Solution** The half-reactions, corresponding half-cell potentials, and their sums are displayed below.

Note that each half-reaction involves the transfer of two moles of electrons; hence,  $n = 2$ . Also,  $E_{\text{cell}}^\circ = 1.56 \text{ V}$ , and the faraday constant,  $F$ , is  $9.6485 \times 10^4 \text{ C/mol } e^-$ . Therefore,

$$\Delta G^\circ = -nFE_{\text{cell}}^\circ = -2 \text{ mol } e^- \times 96,485 \text{ C/mol } e^- \times 1.56 \text{ V} = -3.01 \times 10^5 \text{ J}$$

Recall that (coulombs)  $\times$  (volts) = joules. Thus, the standard free-energy change is **−301 kJ**.

**Answer Check** Free energies of reaction are generally on the order of tens to hundreds of kilojoules, as shown in this answer. Values outside of this range would indicate that you probably made a calculation error.

**Exercise 19.10** What is  $\Delta G^\circ$  at 25°C for the reaction

For data, see Table 19.1.

See Problems 19.73 and 19.74.

**Example 19.10** Calculating the Cell Potential from Free-Energy Change**Gaining Mastery Toolbox****Critical Concept 19.10**

The standard cell potential,  $E_{\text{cell}}^{\circ}$ , is related to the standard free energy change,  $\Delta G^{\circ}$ , of a chemical reaction by the equation  $\Delta G^{\circ} = -nFE_{\text{cell}}^{\circ}$ . For a spontaneous reaction,  $\Delta G^{\circ} < 0$ , and  $E_{\text{cell}}^{\circ} > 0$ .

**Solution Essentials:**

- Free-energy change of electrochemical reaction: ( $\Delta G^{\circ} = -nFE_{\text{cell}}^{\circ}$ )
- Direct calculation of standard cell potential ( $E_{\text{cell}}^{\circ} = E_{\text{cathode}}^{\circ} - E_{\text{anode}}^{\circ}$ )
- Table of Standard Electrode (Reduction) Potentials (Table 19.1)
- Voltaic cell
- Standard free energy ( $\Delta G^{\circ}$ )
- Balanced oxidation–reduction reaction
- Half-reaction

Suppose the reaction of zinc metal and chlorine gas is utilized in a voltaic cell in which zinc ions and chloride ions are formed in aqueous solution.

Calculate the standard potential for this cell at 25°C from standard free energies of formation (see Appendix C).

**Problem Strategy** Calculate  $\Delta G^{\circ}$  and substitute it and the value of  $n$  into the equation  $\Delta G^{\circ} = -nFE_{\text{cell}}^{\circ}$ . Solve for  $E_{\text{cell}}^{\circ}$ .

**Solution** Write the equation with  $\Delta G_f^{\circ}$ 's beneath.

Hence,

$$\begin{aligned} \Delta G^{\circ} &= \sum n\Delta G_f^{\circ}(\text{products}) - \sum m\Delta G_f^{\circ}(\text{reactants}) \\ &= [-147.0 + 2 \times (-131.3)] \text{ kJ} \\ &= -410 \text{ kJ} = -4.10 \times 10^5 \text{ J} \end{aligned}$$

You obtain  $n$  by splitting the reaction into half-reactions.

Each half-reaction involves the transfer of two moles of electrons, so  $n = 2$ . Now you substitute into

$$\begin{aligned} \Delta G^{\circ} &= -nFE_{\text{cell}}^{\circ} \\ -4.10 \times 10^5 \text{ J} &= -2 \text{ mol } e^{-} \times 96,485 \text{ C/mol } e^{-} \times E_{\text{cell}}^{\circ} \end{aligned}$$

Solving for  $E_{\text{cell}}^{\circ}$ , you get  $E_{\text{cell}}^{\circ} = 2.12 \text{ V}$ .

**Answer Check** Because this problem describes a voltaic cell, we should expect the value of  $E_{\text{cell}}^{\circ}$  to be positive.

**Exercise 19.11** Use standard free energies of formation (Appendix C) to obtain the standard cell potential of a cell at 25°C with the reaction

See Problems 19.77 and 19.78.

The measurement of cell potentials gives you yet another way to obtain equilibrium constants. Combining the previous equation,  $\Delta G^{\circ} = -nFE_{\text{cell}}^{\circ}$ , with the equation  $\Delta G^{\circ} = -RT \ln K$  from Section 18.6, you get

$$nFE_{\text{cell}}^{\circ} = RT \ln K$$

or

$$E_{\text{cell}}^{\circ} = \frac{RT}{nF} \ln K = \frac{2.303 RT}{nF} \log K$$

Substituting values for the constants  $R$  and  $F$  at 25°C gives the equation

$$E_{\text{cell}}^{\circ} = \frac{0.0592}{n} \log K \quad (\text{values in volts at } 25^{\circ}\text{C})$$

Figure 19.7 summarizes the various relationships among  $K$ ,  $\Delta G^{\circ}$ , and  $E_{\text{cell}}^{\circ}$ . ◀

The next example illustrates calculation of the thermodynamic equilibrium constant from the cell potential.

This formula is typically written using the common logarithm (base 10) function as it is shown here. The factor 2.303 allows for conversion between the common logarithm and base  $e$  logarithm ( $2.303 \log x = \ln x$ ).

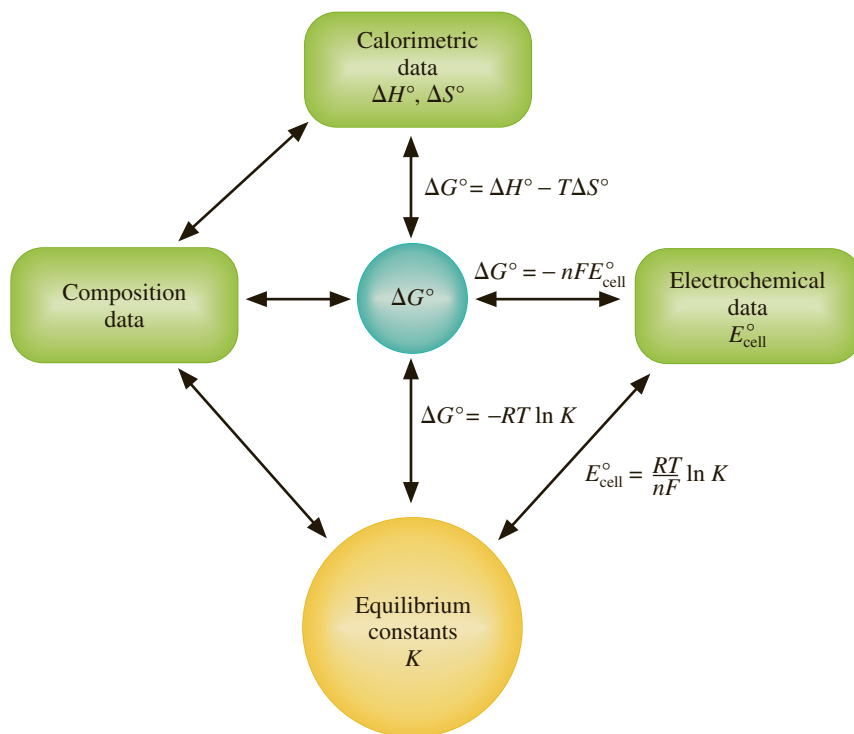

Figure 19.7 ◀

The relationships among  $K$ ,  $\Delta G^\circ$ , and  $E^\circ_{\text{cell}}$ . The diagram shows how composition data, calorimetric data, and electrochemical data are related.

### Example 19.11 Calculating the Equilibrium Constant from Cell Potential

#### Gaining Mastery Toolbox

##### Critical Concept 19.11

For a spontaneous chemical reaction, the equilibrium constant will have a value greater than 1. Under standard conditions, the standard cell potential is related to the equilibrium constant by the equation  $E^\circ_{\text{cell}} = \frac{0.0592}{n} \log K$ .

##### Solution Essentials:

- Relationship between the standard cell potential and the equilibrium constant ( $E^\circ_{\text{cell}} = \frac{0.0592}{n} \log K$ )
- Standard cell potential ( $E^\circ_{\text{cell}}$ )
- Cell notation
- Equilibrium constant

The standard cell potential for the following voltaic cell is 1.10 V:

Calculate the equilibrium constant  $K_c$  for the reaction

**Problem Strategy** Substitute the standard cell potential into the equation relating this quantity to the thermodynamic equilibrium constant,  $K$ . Solve for  $K$ . Note that  $K = K_c$ .

**Solution** The reaction corresponds to the one for the voltaic cell. Note that  $n = 2$ . Substituting into the equation relating  $E^\circ_{\text{cell}}$  and  $K$  gives

$$1.10 = \frac{0.0592}{2} \log K_c$$

Solving for  $\log K_c$ , you find

$$\log K_c = 37.2$$

Now take the antilog of both sides:

$$K_c = \text{antilog}(37.2) = 1.6 \times 10^{37}$$

The number of significant figures in the answer equals the number of decimal places in 37.2 (one). Thus

$$K_c = 2 \times 10^{37}$$

**Answer Check** Whenever the cell potential is a positive number (voltaic cell), you should calculate an equilibrium constant greater than 1.

**Exercise 19.12** Calculate the equilibrium constant  $K_c$  for the following reaction from standard electrode potentials.

See Problems 19.81 and 19.82.

Nernst also formulated the third law of thermodynamics, for which he received the Nobel Prize in 1920.

## 19.7 Dependence of Cell Potential on Concentration

The cell potential of a cell depends on the concentrations of ions and on gas pressures. For that reason, cell potentials provide a way to measure ion concentrations. The pH meter, for example, depends on the variation of cell potential with hydrogen-ion concentration. You can relate cell potentials for various concentrations of ions and various gas pressures to standard electrode potentials by means of an equation first derived by the German chemist Walther Nernst (1864–1941). ◀

### Nernst Equation

Recall that the free-energy change,  $\Delta G$ , is related to the standard free-energy change,  $\Delta G^\circ$ , by the following equation (Section 18.6):

$$\Delta G = \Delta G^\circ + RT \ln Q$$

Here  $Q$  is the thermodynamic reaction quotient. The reaction quotient has the form of the equilibrium constant, except that the concentrations and gas pressures are those that exist in a reaction mixture at a given instant. You can apply this equation to a voltaic cell. In that case, the concentrations and gas pressures are those that exist in the cell at a particular instant. If you substitute  $\Delta G = -nFE_{\text{cell}}$  and  $\Delta G^\circ = -nFE_{\text{cell}}^\circ$  into this equation, you obtain

$$-nFE_{\text{cell}} = -nFE_{\text{cell}}^\circ + RT \ln Q$$

This result rearranges to give the **Nernst equation**, an equation relating the cell potential to its standard cell potential and the reaction quotient.

$$E_{\text{cell}} = E_{\text{cell}}^\circ - \frac{RT}{nF} \ln Q \quad \text{or} \quad E_{\text{cell}} = E_{\text{cell}}^\circ - \frac{2.303 RT}{nF} \log Q$$

If you substitute 298 K (25°C) for the temperature in the Nernst equation and put in values for  $R$  and  $F$ , you get (using common logarithms)

$$E_{\text{cell}} = E_{\text{cell}}^\circ - \frac{0.0592}{n} \log Q \quad (\text{values in volts at } 25^\circ\text{C})$$

You can show from the Nernst equation that the cell potential,  $E_{\text{cell}}$ , decreases as the cell reaction proceeds. As the reaction occurs in the voltaic cell, the concentrations of products increase and the concentrations of reactants decrease. Therefore,  $Q$  and  $\log Q$  increase. The second term in the Nernst equation,  $(0.0592/n) \log Q$ , increases, so that the difference  $E_{\text{cell}}^\circ - (0.0592/n) \log Q$  decreases. Thus, the cell potential,  $E_{\text{cell}}$ , becomes smaller. Eventually the cell potential goes to zero, and the cell reaction comes to equilibrium.

As an example of the computation of the reaction quotient, consider the following voltaic cell:

The cell reaction is

and the expression for the equilibrium constant is

$$K = \frac{[\text{Cd}^{2+}]P_{\text{H}_2}}{[\text{H}^+]^2}$$

Note that the hydrogen-gas concentration is given here in terms of the pressure (in atmospheres). The expression for the reaction quotient has the same form as  $K$ ,

except that the values for the ion concentrations and hydrogen-gas pressures are those that exist in the cell. ► Hence,

$$Q = \frac{[\text{Cd}^{2+}]P_{\text{H}_2}}{[\text{H}^+]^2} = \frac{0.0100 \times 1.00}{(1.00)^2} = 0.0100$$

The next example illustrates a complete calculation of cell potential from the ion concentrations in a voltaic cell.

We have omitted subscript *i*'s on the concentrations and pressures in *Q* to simplify the notation.

### Example 19.12 Calculating the Cell Potential for Nonstandard Conditions

#### Gaining Mastery Toolbox

##### Critical Concept 19.12

The cell potential ( $E_{\text{cell}}$ ) is the cell potential when the reaction is run under nonstandard conditions. Nonstandard conditions are when the temperature, concentration(s), or gas pressures differ from 298 K, 1.0 *M*, and 1.00 atm, respectively. Le Châtelier's principle can be used to estimate the effect that concentration and gas pressure changes will have on the cell potential.

##### Solution Essentials:

- Nernst Equation at 298 K (25°C)  
( $E_{\text{cell}} = E_{\text{cell}}^{\circ} - \frac{0.0592}{n} \log Q$ )
- Standard cell potential ( $E_{\text{cell}}^{\circ}$ )
- Cell potential ( $E_{\text{cell}}$ )
- Reaction quotient (*Q*)
- Balanced oxidation–reduction reaction

What is the cell potential of the following voltaic cell at 25°C?

The standard cell potential of this cell is 1.10 V.

**Problem Strategy** From the cell reaction, deduce the value of *n*; then calculate *Q*. Now substitute *n*, *Q*, and  $E_{\text{cell}}^{\circ}$  into the Nernst equation to obtain  $E_{\text{cell}}$ .

**Solution** The cell reaction is

The number of moles of electrons transferred is two; hence, *n* = 2. The reaction quotient is

$$Q = \frac{[\text{Zn}^{2+}]}{[\text{Cu}^{2+}]} = \frac{1.00 \times 10^{-5}}{0.100} = 1.00 \times 10^{-4}$$

The standard cell potential is 1.10 V, so for this reaction running at 25°C, the Nernst equation becomes

$$\begin{aligned} E_{\text{cell}} &= E_{\text{cell}}^{\circ} - \frac{0.0592}{n} \log Q \\ &= 1.10 - \frac{0.0592}{2} \log (1.0 \times 10^{-4}) \\ &= 1.10 - (-0.12) = 1.22 \text{ V} \end{aligned}$$

The cell potential is **1.22 V**.

**Answer Check** Whenever you perform a calculation involving nonstandard cell concentrations, you can use Le Châtelier's principle to see if your answer is reasonable. Recall that standard cell concentrations are equivalent and are 1.00 *M*. At standard concentrations, the cell potential is 1.10 V. In this problem, the concentration of the product ( $\text{Zn}^{2+}$ ) is  $1.0 \times 10^{-5} M$ , whereas the concentration of the reactant ( $\text{Cu}^{2+}$ ) is 0.100 *M*. With these concentrations, we would expect this spontaneous reaction to be shifted toward products, thereby resulting in a value of  $E_{\text{cell}}$  greater than the standard value, which is what we observe.

**Exercise 19.13** What is the cell potential of the following voltaic cell at 25°C?

See Problems 19.85 and 19.86.

## Determination of pH

The pH of a solution can be obtained very accurately from cell potential measurements, using the Nernst equation to relate cell potential to pH. To see how this is done, suppose you have a test solution whose pH you would like to determine. You set up a voltaic cell as follows: You use the test solution as the electrolyte for a hydrogen

electrode and bubble in hydrogen gas at 1 atm. (The hydrogen electrode is shown in Figure 19.5.) Now connect this hydrogen electrode to a standard zinc electrode to give the following cell:

The cell reaction is

The cell potential depends on the hydrogen-ion concentration of the test solution, according to the Nernst equation. The standard cell potential of the cell equals 0.76 V, and

$$Q = \frac{[\text{Zn}^{2+}]P_{\text{H}_2}}{[\text{H}^+]^2} = \frac{1}{[\text{H}^+]^2}$$

Substituting into the Nernst equation, you obtain

$$E_{\text{cell}} = 0.76 - \frac{0.0592}{2} \log \frac{1}{[\text{H}^+]^2} = 0.76 + 0.0592 \log [\text{H}^+]$$

where  $[\text{H}^+]$  is the hydrogen-ion concentration of the test solution.

To obtain the relationship between the cell potential ( $E_{\text{cell}}$ ) and pH, you substitute the following into the preceding equation: ◀

$$\text{pH} = -\log [\text{H}^+]$$

The result is

$$E_{\text{cell}} = 0.76 - 0.0592 \text{ pH}$$

Which you can rearrange to give the pH directly in terms of the cell potential:

$$\text{pH} = \frac{0.76 - E_{\text{cell}}}{0.0592}$$

In this way, measurement of the cell potential gives you the pH of the solution.

The hydrogen electrode is seldom employed in routine laboratory work, because it is awkward to use. It is often replaced by a *glass electrode*. This compact electrode (see Figure 19.8) consists of a silver wire coated with silver chloride immersed in a solution of dilute hydrochloric acid. The electrode solution is separated from the test solution by a thin glass membrane, which develops a potential across it depending on the hydrogen-ion concentrations on its inner and outer surfaces. A mercury–mercury(I) chloride (calomel) electrode is often used as the other electrode. The cell potential depends linearly on the pH. In a common arrangement, the cell potential is measured with a voltmeter that reads pH directly (see Figure 15.7).

The glass electrode is an example of an *ion-selective electrode*. Many electrodes have been developed that are sensitive to a particular ion, such as  $\text{K}^+$ ,  $\text{NH}_4^+$ ,  $\text{Ca}^{2+}$ , or  $\text{Mg}^{2+}$ . They can be used to monitor solutions of that ion. It is even possible to measure the concentration of a nonelectrolyte. To measure urea,  $\text{NH}_2\text{CONH}_2$ , in solution, you can use an electrode selective to  $\text{NH}_4^+$  that is coated with a gel containing the enzyme urease. (An enzyme is a biochemical catalyst.) The gel is held in place around the electrode by means of a nylon net. Urease catalyzes the decomposition of urea to ammonium ion, whose concentration is measured.

Keeping in mind that  $\text{H}^+$  is a shorthand representation of  $\text{H}_3\text{O}^+$ , the equation for pH used here is the same as presented in Chapter 15 ( $\text{pH} = -\log [\text{H}_3\text{O}^+]$ ).

**Figure 19.8** ▲

**A glass electrode** *Left:* A small, commercial glass electrode. *Right:* A sketch showing the construction of a glass electrode for measuring hydrogen-ion concentrations.

**Exercise 19.14** What is the nickel(II)-ion concentration in the voltaic cell

if the cell potential is 0.34 V at 25°C?

See Problems 19.89 and 19.90.

**Figure 19.9** ▲

**Leclanché dry cell** The cell has a zinc anode and a graphite rod with a paste of  $\text{MnO}_2$ ,  $\text{ZnCl}_2$ ,  $\text{NH}_4\text{Cl}$ , and  $\text{C}$  as the cathode.

**Figure 19.10** ▲

**A small alkaline dry cell** The anode is zinc powder and the cathode is  $\text{MnO}_2$ , as in the Leclanché cell; however, the electrolyte is  $\text{KOH}$ .

**CONCEPT CHECK 19.3**

Consider a voltaic cell,  $\text{Fe}(s) | \text{Fe}^{2+}(aq) || \text{Cu}^{2+}(aq) | \text{Cu}(s)$ , being run under standard conditions.

- Is  $\Delta G^\circ$  positive or negative for this process?
- Change the concentrations from their standard values in such a way that  $E_{\text{cell}}$  is reduced. Write your answer using the shorthand notation of Section 19.3.

## 19.8 Some Commercial Voltaic Cells

We commonly use voltaic cells as convenient, portable sources of energy. Flashlights and radios are examples of devices that are often powered by the **zinc-carbon**, or **Leclanché, dry cell** (Figure 19.9). *This voltaic cell has a zinc can as the anode; a graphite rod in the center, surrounded by a paste of manganese dioxide, ammonium and zinc chlorides, and carbon black, is the cathode.* The electrode reactions are complicated but are approximately these:

The voltage of this dry cell is initially about 1.5 V, but it decreases as current is drawn off. The voltage also deteriorates rapidly in cold weather.

An **alkaline dry cell** (Figure 19.10) is *similar to the Leclanché cell, but it has potassium hydroxide in place of ammonium chloride.* This cell performs better under current drain and in cold weather. The half-reactions are

A dry cell is not truly “dry,” because the electrolyte is an aqueous paste. Solid-state batteries have been developed, however. One of these is a **lithium-iodine battery**, a voltaic cell in which the anode is lithium metal and the cathode is an  $\text{I}_2$  complex. These solid-state electrodes are separated by a thin crystalline layer of lithium iodide (Figure 19.11). Current is carried through the crystal by diffusion of  $\text{Li}^+$  ions. Although the cell has high resistance and therefore low current, the

**Figure 19.11** ▲

**A solid-state lithium-iodine battery** The anode is lithium metal and the cathode is a complex of iodine,  $\text{I}_2$ ; the electrodes are separated by a thin crystalline layer of lithium iodide. The battery consists of two cells enclosed in a titanium shell.

**Figure 19.12** ▲

**A lead storage battery** Each cell delivers about 2 V, and a battery consisting of six cells in series gives about 12 V.

battery is very reliable and is used to power heart pacemakers. The battery is implanted within the patient's chest and lasts about ten years before it has to be replaced.

Once a dry cell is completely discharged (has come to equilibrium), the cell is not easily reversed, or recharged, and is normally discarded. Some types of cells are rechargeable after use, however. An important example is the **lead storage cell**. *This voltaic cell consists of electrodes of lead alloy grids; one electrode is packed with a spongy lead to form the anode, and the other electrode is packed with lead(IV) oxide to form the cathode* (see Figure 19.12). Both are bathed in an aqueous solution of sulfuric acid,  $\text{H}_2\text{SO}_4$ . The half-cell reactions during discharge are

White lead(II) sulfate coats each electrode during discharge, and sulfuric acid is consumed. Each cell delivers about 2 V, and a battery consisting of six cells in series gives about 12 V.

After the lead storage battery is discharged, it is recharged from an external electric current. The previous half-reactions are reversed. Some water is decomposed into hydrogen and oxygen gas during this recharging, so more water may have to be added at intervals. However, newer batteries use lead electrodes containing some calcium metal; the calcium–lead alloy resists the decomposition of water. These **maintenance-free** batteries are sealed (Figure 19.13).

**Figure 19.13** ▲

**A maintenance-free battery**

This lead storage battery contains calcium–lead alloy grids for electrodes. This alloy resists the decomposition of water, so the battery can be sealed.

The **nickel–cadmium cell** (nicad cell) is a common storage battery. It is *a voltaic cell consisting of an anode of cadmium and a cathode of hydrated nickel oxide (approximately  $\text{NiOOH}$ ) on nickel; the electrolyte is potassium hydroxide*. Nicad batteries were the first widely used rechargeable batteries for consumer devices such as calculators, portable power tools, shavers, and toothbrushes. The half-cell reactions during discharge are

These half-reactions are reversed when the cell is recharged. Although nicad batteries have a number of advantages as rechargeable batteries (for example, they can be charged and discharged through many cycles), they do have a major disadvantage: the cadmium anode. Cadmium is highly toxic to most life, so it is a significant environmental hazard. Many governments strictly limit their use.

For many applications, the *nickel-metal hydride* (NiMH) battery is a good substitute for nicad batteries, retaining most of their advantages. Instead of cadmium, these batteries use a metal-alloy hydride for the anode, but have the same cathode as the nicad battery. Relative to nicad batteries of similar capacity, nickel-metal hydride batteries are lighter, while being less harmful to the environment. The half-reactions, in which M stands for the metal alloy, are

The cell potential for the reaction is 1.2 volts, the same as for the nicad battery.

The *lithium-ion* battery (Figure 19.14) has become a popular battery for portable devices. (The essay at the end of this section describes this battery in detail.) It has two advantages over the nickel-hydride battery: lower weight for given energy output and a higher cell voltage (3.6 volts versus 1.6 volts). Typically, the lithium-ion battery has a carbon anode (graphite), containing lithium ions, and a lithium metal oxide, such as lithium cobalt oxide,  $\text{LiCoO}_2$ , as the cathode. Denoting the graphite with lithium ions as  $\text{Li}_x\text{C}$ , the half-cell reactions for this battery during discharge are

As the battery discharges, lithium ions move from  $\text{Li}_x\text{C}(s)$  to  $\text{LiCoO}_2$ . The half-reactions are reversed when the battery is charged.

A **fuel cell** is essentially a battery, but it differs in operating with a continuous supply of energetic reactants, or fuel. Figure 19.15 shows a proton-exchange membrane (PEM) fuel cell that uses hydrogen and oxygen. On one side of the cell, the anode, hydrogen passes through a porous material containing a platinum catalyst, allowing the following reaction to occur:

**Figure 19.15** ◀

**A hydrogen fuel cell** At the anode, hydrogen gas enters a chamber where a porous platinum catalyst oxidizes the hydrogen to  $\text{H}^+(aq)$  ions at the anode. The  $\text{H}^+$  ions then migrate through a special proton-exchange membrane (PEM) and move to the cathode; the proton-exchange membrane allows only the very small  $\text{H}^+(aq)$  ions to pass from the anode to the cathode. At the cathode, oxygen gas enters the cell, where it comes into contact with a platinum catalyst that facilitates the reduction of  $\text{O}_2(g)$  in the presence of the  $\text{H}^+(aq)$  and the electrons from the oxidation reaction to produce water. The net chemical change is the reaction of hydrogen with oxygen to produce water. This fuel cell has a measured potential of 0.7 V and, unlike many other types of fuel cells, can run at temperatures under  $100^\circ\text{C}$ .

**Figure 19.14** ▲

**Lithium-ion batteries** These batteries are lightweight and long lasting when compared with other types of batteries.

## Daily Life

A CHEMIST Looks at . . .

## Lithium-Ion Batteries

According to estimates, over 60% of the people on Earth have a cell phone, and the Pew Research Center reported in a 2014 survey that over 98% of young American adults have a cell phone. Most of these cell phones are powered by rechargeable lithium-ion batteries (which are composed of one or more lithium-ion cells). How do these lithium-ion cells work? What are their advantages for portable devices such as cell phones?

Like similar electrochemical cells we discussed in the text, lithium-ion cells have an anode and a cathode separated by an electrolyte. Their detailed structure, though, is rather different from the simple voltaic cell with metal electrodes. Each electrode of a lithium-ion cell is composed of a material having a layer structure, one layer on top of another, between which lithium ions can be reversibly inserted or extracted.

The actual electrode and electrolyte materials depend on the particular battery, but a common lithium-ion cell has one electrode composed of lithium cobalt oxide,  $\text{LiCoO}_2$ , and the other electrode of graphite (see the accompanying figure). Lithium cobalt oxide has a layer structure, with layers of lithium ions,  $\text{Li}^+$ , alternating with layers of cobalt oxide,  $\text{CoO}_2^-$ . Graphite has a layer structure in which one sheet of covalently bonded carbon atoms is normally held to another sheet by van der Waals forces (described in Section 11.6). During battery charging, lithium ions move from the  $\text{LiCoO}_2$  electrode to the graphite electrode, lodging between graphite sheets, while electrons from the external circuit give some of the carbon atoms a negative charge to balance that of the lithium ions. Ionic bonds form between the lithium ions and negatively charged carbon atoms. The half-reactions during charging, in which a fraction of the lithium ions,  $x$ , moves from the  $\text{LiCoO}_2$  electrode to the graphite electrode, are:

These half-reactions are reversed during discharge, so that the graphite electrode is the anode (becoming the negative electrode) and the lithium cobalt oxide electrode is the cathode (the positive electrode).

The electrolyte is a nonaqueous solution of a lithium salt, for example, lithium hexafluorophosphate,  $\text{Li}^+(\text{PF}_6^-)$ .

(A nonaqueous solvent is required, because the voltage in a lithium-ion cell is higher than what would electrolyze water.) The electrolyte is partitioned by a microporous polymer sheet, or separator, to keep the electrodes apart.

The environments of the lithium ions at the two electrodes are different, so the free energies of the ions at the anode and cathode are different. During discharge, lithium ions flow from the graphite electrode, where the ions have high free energy, through the electrolyte to the  $\text{LiCoO}_2$  electrode, where the ions have lower free energy. This decrease of free energy of the lithium ions is the source of the battery power.

Lithium is a very light element, and it is also very reactive, so it can store more energy for a given mass and size. High energy storage for given mass and size of battery is a special requirement of portable devices. Cell phones, tablets, and laptop computers all use lithium-ion batteries for this reason. Gas-electric hybrid cars and plug-in electric cars are another use for these batteries. To be competitive with fossil fuels, though, the batteries will need to have even greater energy storage capacities than they have. Research for better batteries with newer electrode materials is intense.

**Diagram of a lithium-ion cell.** During discharge, lithium ions move from the graphite anode through the electrolyte and separator to the lithium cobalt oxide cathode. Electrons move through an external circuit from the anode to the cathode.

■ See Problems 19.129 and 19.130.

The  $\text{H}^+(aq)$  ions then migrate through a proton-exchange membrane to the other side of the cell to participate in the cathode reaction with  $\text{O}_2(g)$ :

**Figure 19.16** ▲

**The electrochemical process involved in the rusting of iron** Here a single drop of water containing ions forms a voltaic cell in which iron is oxidized to iron(II) ion at the center of the drop (this is the anode). Oxygen gas from air is reduced to hydroxide ion at the periphery of the drop (the cathode). Hydroxide ions and iron(II) ions migrate together and react to form iron(II) hydroxide. This is oxidized to iron(III) hydroxide by more  $O_2$  that dissolves at the surface of the drop. Iron(III) hydroxide precipitates, and this settles to form rust on the surface of the iron.

The sum of the half-reactions (note that the anode reaction must be multiplied by 2 prior to adding) is

which is the net reaction in the fuel cell. The first applications of PEM fuel cells were in space, but more recently, they have provided power for lighting, emergency power generators, communications equipment, automobiles, and buses. Other types of cells using other materials and fuels such as hydrocarbons or methanol are either in commercial production or under development.

Another use of voltaic cells is to control the corrosion of underground pipelines and tanks. Such pipelines and tanks are usually made of steel, an alloy of iron, and their corrosion or rusting is an electrochemical process.

Consider the rusting that occurs when a drop of water is in contact with iron. The edge of the water drop exposed to the air becomes one pole of a voltaic cell (see Figure 19.16). At this edge, molecular oxygen from air is reduced to hydroxide ion in solution.

The electrons for this reduction are supplied by the oxidation of metallic iron at the center of the drop, which acts as the other pole of the voltaic cell.

These electrons flow from the center of the drop through the metallic iron to the edge of the drop. The metallic iron functions as the external circuit between the cell poles.

Ions move within the water drop, completing the electric circuit. Iron(II) ions move outward from the center of the drop, and hydroxide ions move inward from the edge. The two ions meet in a doughnut-shaped region, where they react to precipitate iron(II) hydroxide.

This precipitate is quickly oxidized by oxygen to rust (approximated by the formula  $Fe_2O_3 \cdot H_2O$ ).

If a buried steel pipeline (Figure 19.17) is connected to an active metal (that is, a highly electropositive substance) such as magnesium, a voltaic cell is formed;

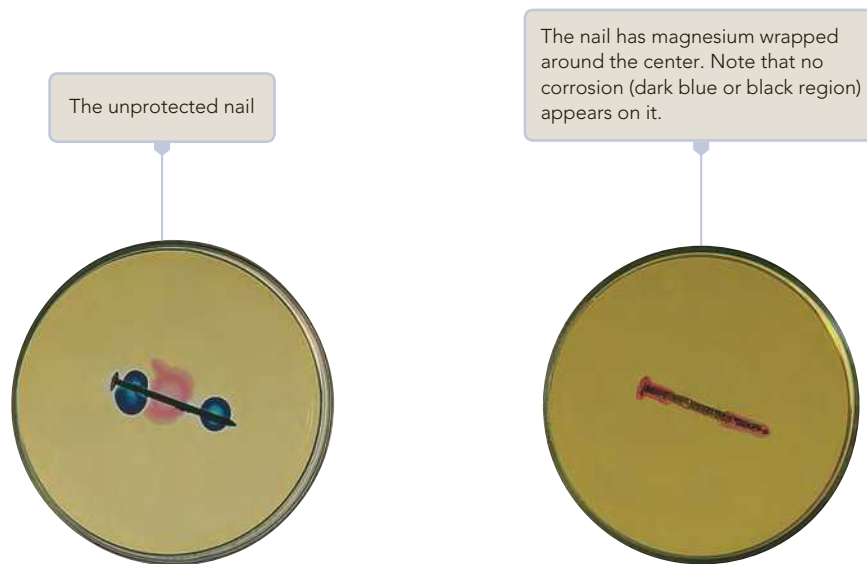

**Figure 19.17** ▲

**Cathodic protection of a buried steel pipe** Iron in the steel becomes the cathode in an iron–magnesium voltaic cell. Magnesium is then oxidized in preference to iron.

Figure 19.18 ►

**A demonstration of cathodic**

**protection** The nails are in a gel containing phenolphthalein indicator and potassium ferricyanide. Iron corrosion yields  $\text{Fe}^{2+}$ , which reacts with ferricyanide ion to give a dark blue precipitate. Where  $\text{OH}^-$  forms, phenolphthalein appears pink.

the active metal is the anode and iron becomes the cathode. Wet soil forms the electrolyte, and the electrode reactions are

As the cathode, the iron-containing steel pipe is protected from oxidation. Of course, the magnesium rod is eventually consumed and must be replaced, but this is cheaper than digging up the pipeline. This use of an active metal to protect iron from corrosion is called *cathodic protection*. See Figure 19.18 for a laboratory demonstration of cathodic protection.

✓ **CONCEPT CHECK 19.4**

Keeping in mind that seawater contains a number of ions, explain why seawater corrodes iron much faster than freshwater.

## ► Electrolytic Cells

An *electrolytic cell*, you may recall, is an electrochemical cell in which an external energy source drives an otherwise nonspontaneous reaction. *The process of producing a chemical change in an electrolytic cell* is called **electrolysis**. Many important substances, including aluminum and chlorine, are produced commercially by electrolysis. We will begin by looking at the electrolysis of molten salts.

### 19.9 Electrolysis of Molten Salts

Figure 19.19 shows a simple electrolytic cell. Wires from a battery are connected to electrodes that dip into molten sodium chloride. ( $\text{NaCl}$  melts at  $801^\circ\text{C}$ .) At the electrode connected to the negative pole of the battery, globules of sodium metal form; chlorine gas evolves from the other electrode. The half-reactions are

As noted earlier (Section 19.2), the *anode* is the electrode at which oxidation occurs, and the *cathode* is the electrode at which reduction occurs (these definitions hold for electrolytic cells as well as for voltaic cells). Thus, during the

**Figure 19.19** ◀

**Electrolysis of molten sodium chloride** Sodium metal forms at the cathode from the reduction of  $Na^+$  ion; chlorine gas forms at the anode from the oxidation of  $Cl^-$  ion. Sodium metal is produced commercially this way, although the commercial cell must be designed to collect the products and to keep them away from one another.

electrolysis of molten  $NaCl$ , the reduction of  $Na^+$  to  $Na$  occurs at the cathode, and the oxidation of  $Cl^-$  to  $Cl_2$  occurs at the anode (note the labeling of electrodes in Figure 19.19).

This electrolysis of molten  $NaCl$  is used commercially to obtain sodium metal from sodium chloride. A **Downs cell** is a commercial electrochemical cell used to obtain sodium metal by the electrolysis of molten sodium chloride (Figure 19.20). The cell is constructed to keep the products of the electrolysis separate, because they would otherwise react. Calcium chloride is added to the sodium chloride to lower the melting point from  $801^\circ C$  for  $NaCl$  to about  $580^\circ C$  for the mixture. (Remember that the melting point, or freezing point, of a substance is lowered by the addition of a solute.) You obtain the cell reaction by adding the half-reactions.

A number of other reactive metals are obtained by the electrolysis of a molten salt or ionic compound. Lithium, magnesium, and calcium metals are all obtained

**Figure 19.20** ◀

**A Downs cell for the preparation of sodium metal** In this commercial cell, sodium is produced by the electrolysis of molten sodium chloride. The salt contains calcium chloride, which is added to lower the melting point of the mixture. Liquid sodium forms at the cathode, where it rises to the top of the molten salt and collects in a tank. Chlorine gas is a by-product.

by the electrolysis of the chlorides. The first commercial preparation of sodium metal adapted the method used by Humphry Davy when he discovered the element in 1807. Davy electrolyzed molten sodium hydroxide, NaOH, whose melting point (318°C) is relatively low for an ionic compound. The half-reactions are

Many of the commercial uses of electrolysis involve aqueous solutions. We will look at electrolysis in aqueous solution in the next section.

**Exercise 19.15** Write the half-reactions for the electrolysis of the following molten compounds: a. KCl; b. KOH.

See Problems  
19.91 and 19.92.

## 19.10 Aqueous Electrolysis

In the electrolysis of a molten salt, the possible half-reactions are usually limited to those involving ions from the salt. When you electrolyze an aqueous solution of an ionic compound, however, you must consider the possibility that water is involved at one or both electrodes. Let us look at the possible half-reactions involving water.

Water can be reduced or oxidized in half-reactions, and you can easily obtain these half-reactions. To do this, first note the species likely to be involved. In addition to H<sub>2</sub>O, these are H<sub>2</sub>, O<sub>2</sub>, H<sup>+</sup>, and OH<sup>-</sup>. Only H<sub>2</sub> and O<sub>2</sub> involve a change of oxidation state. Hydrogen has a lower oxidation state in H<sub>2</sub> (0) than in H<sub>2</sub>O (+1), whereas the oxygen has a higher oxidation state in O<sub>2</sub> (0) than in H<sub>2</sub>O (-2). Therefore, you can reduce water to H<sub>2</sub> or oxidize it to O<sub>2</sub>.

Consider the reduction half-reaction. It must involve the reduction of H<sub>2</sub>O to H<sub>2</sub>. You need to balance the half-reaction by putting an oxygen-containing species on the right. The only species in which there are no changes in oxidation states from those in H<sub>2</sub>O is OH<sup>-</sup>. The balanced half-reaction is

You can obtain the oxidation half-reaction for water in a similar way. It involves the oxidation of H<sub>2</sub>O to O<sub>2</sub>. You need to put a hydrogen-containing species on the right side of the equation to balance it. The only species in which there is no change in oxidation state is H<sup>+</sup>. The balanced half-reaction is

Now let us consider the electrolysis of different aqueous solutions and try to decide what the half-reactions might be. Once you have the half-reactions, you can obtain the overall chemical change due to the electrolysis.

### Electrolysis of Sulfuric Acid Solutions

To decide what is likely to happen during the electrolysis of a solution of sulfuric acid, H<sub>2</sub>SO<sub>4</sub>, you must consider the half-reactions involving ionic species from H<sub>2</sub>SO<sub>4</sub>, in addition to those involving water. Sulfuric acid is a strong acid and ionizes completely into H<sup>+</sup> and HSO<sub>4</sub><sup>-</sup>. The HSO<sub>4</sub><sup>-</sup> ion is relatively strong and for the most part ionizes into H<sup>+</sup> and SO<sub>4</sub><sup>2-</sup>. Therefore, the species you have to look at are H<sup>+</sup>, SO<sub>4</sub><sup>2-</sup>, and H<sub>2</sub>O.

At the cathode, the possible reduction half-reactions are

At the anode, the possible oxidation half-reactions are

In the first half-reaction, the sulfate ion,  $\text{SO}_4^{2-}$ , is oxidized to the peroxydisulfate ion,  $\text{S}_2\text{O}_8^{2-}$ . The  $\text{S}_2\text{O}_8^{2-}$  ion contains the peroxy group  $-\text{O}-\text{O}-$  and therefore has O in the  $-1$  oxidation state. Oxygen in this half-reaction is oxidized from oxidation state  $-2$  to  $-1$ .

Consider the cathode reaction. As you can easily show, the two reduction half-reactions (reduction of  $\text{H}^+$  and reduction of  $\text{H}_2\text{O}$ ) in acidic solution are essentially equivalent, although this is not immediately obvious. Consider the reduction of water to give  $\text{H}_2$  and  $\text{OH}^-$ . In acidic solution,  $\text{OH}^-$  reacts with  $\text{H}^+$  to give  $\text{H}_2\text{O}$ . The net result is obtained by adding the two reactions.

You can consider the cathode reaction to be the reduction of  $\text{H}^+$ .

For the anode, consider the oxidation half-reactions and their oxidation potentials (which equal the electrode potentials with signs reversed).

The species whose oxidation half-reaction has the larger (less negative) oxidation potential is the more easily oxidized. Therefore, under standard conditions, you expect  $\text{H}_2\text{O}$  to be oxidized in preference to  $\text{SO}_4^{2-}$ .

A note of caution must be added here. Electrode potentials are measured under conditions in which the half-reactions are at or very near equilibrium. In electrolysis, in which the half-reactions can be far from equilibrium, you may have to supply a larger voltage than predicted from electrode potentials. This additional voltage, called *overvoltage*, can be fairly large (several tenths of a volt), particularly for forming a gas. This means that in trying to predict which of two half-reactions is the one that actually occurs at an electrode, you must be especially careful if the electrode potentials are within several tenths of a volt of one another. For example, the standard oxidation potential for  $\text{O}_2$  is  $-1.23 \text{ V}$ , but because of overvoltage, the effective oxidation potential may be several tenths of a volt lower (more negative). The sulfate ion is so difficult to oxidize ( $-E^\circ = -2.01 \text{ V}$ ), however, that the previous conclusion about the anode half-reaction in electrolyzing aqueous sulfuric acid is unaltered.

You obtain the cell reaction by adding the half-reactions that occur at the electrodes.

The net cell reaction is simply the *electrolysis of water*. Where electricity is cheap, hydrogen can be prepared commercially by the electrolysis of water. Here  $\text{H}_2\text{SO}_4$  was used as an electrolyte; however, various electrolytes can be used, including  $\text{NaCl}$ .

### Electrolysis of Sodium Chloride Solutions

When you electrolyze an aqueous solution of sodium chloride,  $\text{NaCl}$ , the possible species involved in half-reactions are  $\text{Na}^+$ ,  $\text{Cl}^-$ , and  $\text{H}_2\text{O}$ . The possible cathode half-reactions are

Under standard conditions, you expect  $\text{H}_2\text{O}$  to be reduced in preference to  $\text{Na}^+$ , which agrees with what you observe. Hydrogen gas evolves at the cathode. ◀

The possible anode half-reactions are

Under standard-state conditions, you might expect  $\text{H}_2\text{O}$  to be oxidized in preference to  $\text{Cl}^-$ . However, the potentials are close and overvoltages at the electrodes could alter this conclusion.

It is possible, nevertheless, to give a general statement about the product expected at the anode. Electrode potentials, as you have seen, depend on concentrations. It turns out that when the solution is concentrated enough in  $\text{Cl}^-$ ,  $\text{Cl}_2$  is the product, but in dilute solution,  $\text{O}_2$  is the product. To see this, you would simply apply the Nernst equation to the  $\text{Cl}^-|\text{Cl}_2$  half-reaction.

Starting with very dilute  $\text{NaCl}$  solutions, you would find that the oxidation potential of  $\text{Cl}^-$  is very negative, so  $\text{H}_2\text{O}$  is reduced in preference to  $\text{Cl}^-$ . But as you increased the  $\text{NaCl}$  concentration, you would find that the oxidation potential of  $\text{Cl}^-$  increases until eventually  $\text{Cl}^-$  is oxidized in preference to  $\text{H}_2\text{O}$ . The product changes from  $\text{O}_2$  to  $\text{Cl}_2$ .

The half-reactions and cell reaction for the electrolysis of aqueous sodium chloride to chlorine and hydroxide ion are as follows:

Because the electrolysis started with sodium chloride, the cation in the electrolyte solution is  $\text{Na}^+$ . When you evaporate the electrolyte solution at the cathode, you obtain sodium hydroxide,  $\text{NaOH}$ . Figure 19.21 shows the similar electrolysis of aqueous potassium iodide,  $\text{KI}$ .

The electrolysis of aqueous sodium chloride is the basis of the *chlor-alkali industry*, the major commercial source of chlorine and sodium hydroxide. Commercial cells are of several types, but in each the main problem is to keep the products separate, because chlorine reacts with aqueous sodium hydroxide.

Figure 19.22 shows a modern **chlor-alkali membrane cell**, a cell for the electrolysis of aqueous sodium chloride in which the anode and cathode compartments are separated by a special plastic membrane that allows only cations to pass through it. Sodium chloride solution is added to the anode compartment, where chloride ion is oxidized to chlorine. The sodium ions carry the current from the anode to the cathode by passing through the membrane. Water is added at the top of the cathode compartment, where it is reduced to hydroxide ion, and sodium hydroxide solution is removed at the bottom of the cathode compartment.

The  $\text{OH}^-$  concentration is actually  $1 \times 10^{-7} \text{ M}$ . From Nernst's equation,  $E$  for the reduction of  $\text{H}_2\text{O}$  is  $-0.41 \text{ V}$ , so you still conclude that  $\text{H}_2\text{O}$  is reduced in preference to  $\text{Na}^+$ .

Figure 19.21 ▲

**Electrolysis of aqueous potassium iodide** Iodine forms at the anode by the oxidation of  $\text{I}^-$  ion. Iodine reacts with iodide ion to form  $\text{I}_3^-$  ion, which is red-brown. Hydrogen bubbles and hydroxide ion form at the cathode by the reduction of water.

Figure 19.22 ◀

**A chlor-alkali membrane cell** Sodium chloride solution enters the anode compartment, where  $\text{Cl}^-$  ion is oxidized to  $\text{Cl}_2$ . Sodium ion migrates from the anode compartment through the membrane to the cathode compartment. Here water is reduced to hydrogen and  $\text{OH}^-$  ion. Sodium hydroxide solution is removed at the bottom of the cathode compartment.

The older **chlor-alkali mercury cell** is a cell for the electrolysis of aqueous sodium chloride in which mercury metal is used as the cathode (Figure 19.23). At the mercury cathode, sodium ion is reduced in preference to water. Sodium ion is reduced to sodium to form a liquid sodium–mercury alloy called sodium amalgam. (An *amalgam* is an alloy of mercury with any of various other metals.)

Sodium amalgam circulates from the electrolytic cell to the amalgam decomposer. The amalgam and graphite particles in the decomposer form the electrodes of many voltaic cells, in which sodium reacts with water to give sodium hydroxide solution and hydrogen gas. Historically, loss of mercury from these cells has been a source of mercury pollution of waterways.

### Electroplating of Metals

Many metals are protected from corrosion by plating them with other metals. Zinc coatings are often used to protect steel, because the coat protects the steel by cathodic protection even when the zinc coat is scratched (see end of Section 19.8). A thin zinc

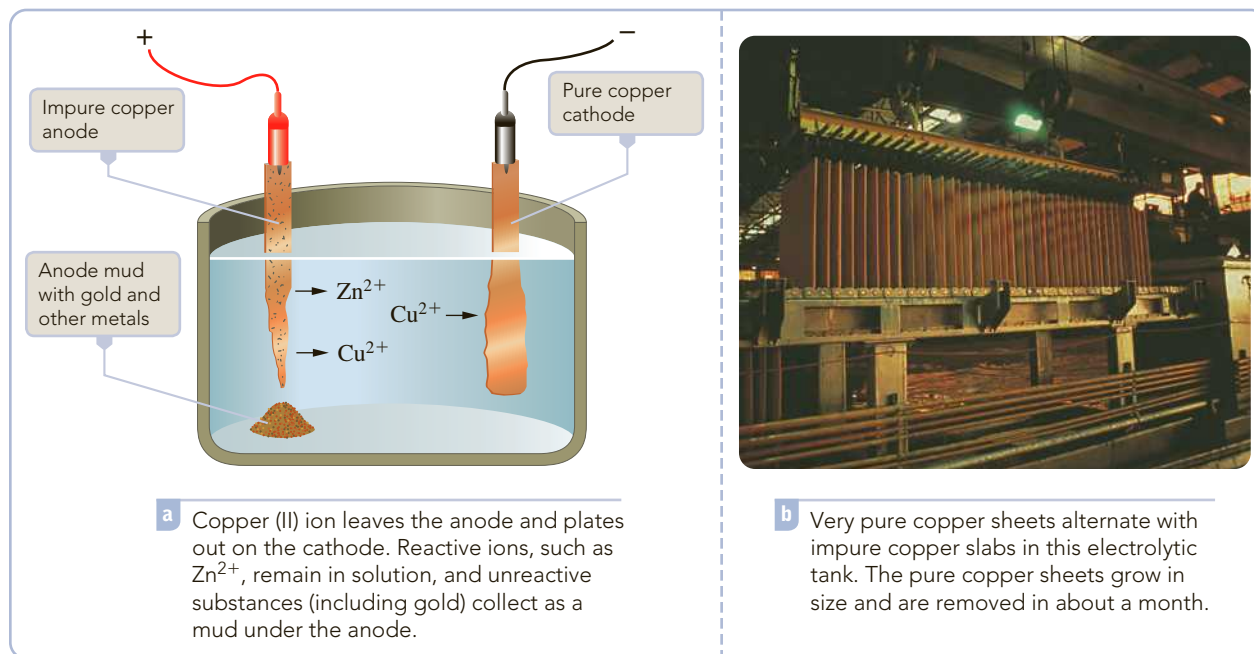

Figure 19.23 ◀

**A chlor-alkali mercury cell** Chloride ion oxidizes to chlorine gas at the graphite anodes (+ electrodes), and sodium deposits at the mercury cathode. Sodium amalgam (a liquid sodium–mercury alloy) circulates to the amalgam decomposer, where sodium reacts with water to form  $\text{NaOH}(\text{aq})$  and  $\text{H}_2$ .

Figure 19.24 ▲

**Purification of copper by electrolysis**

coating can be applied to steel by *electrogalvanizing*, or zinc electroplating. (Galvanized steel has a thick zinc coating obtained by dipping the object in molten zinc.) The steel object is placed in a bath of zinc salts and made the cathode in an electrolytic cell. The cathode half-reaction is

Electrolysis is also used to purify some metals. For example, copper for electrical use, which must be very pure, is purified by electrolysis. Slabs of impure copper serve as anodes, and pure copper sheets serve as cathodes; the electrolyte bath is copper(II) sulfate,  $CuSO_4$  (Figure 19.24). During the electrolysis, copper(II) ions leave the anode slabs and plate out on the cathode sheets. Less reactive metals, such as gold, silver, and platinum, that were present in the impure copper form a valuable mud that collects on the bottom of the electrolytic cell. Metals more reactive than copper remain as ions in the electrolytic bath. After about a month in the electrolytic cell, the pure copper cathodes are much enlarged and are removed from the cell bath.

**Example 19.13 Predicting the Half-Reactions in an Aqueous Electrolysis****Gaining Mastery Toolbox****Critical Concept 19.13**

With aqueous electrolysis, one must consider the possibility of the oxidation or reduction of water. For the reduction of water,  $E^{\circ} = -0.83$  V, and for the oxidation of water,  $-E^{\circ} = -1.23$  V. If the reduction half-reaction is less (more negative) than  $-0.83$  V, water will be reduced during electrolysis. If the oxidation half-reaction is more negative than  $-1.23$  V, water will be oxidized by electrolysis.

What do you expect to be the half-reactions in the electrolysis of aqueous copper(II) sulfate?

**Problem Strategy** From the problem, determine which species might be involved in the electrolysis. Write the half-reactions for these species, identifying those that could undergo reduction (cathode) and those that could undergo oxidation (anode). Using the electrode potentials of the half-reactions, determine which are most likely to occur.

**Solution** The species you should consider for half-reactions are  $Cu^{2+}(aq)$ ,  $SO_4^{2-}(aq)$ , and  $H_2O$ .

Possible cathode half-reactions are

(continued)

**Example 19.13** (continued)**Solution Essentials:**

- Water-reduction half-reaction:  
 $2\text{H}_2\text{O}(l) + 2\text{e}^- \longrightarrow \text{H}_2(g) + 2\text{OH}^-(aq);$   
 $E^\circ = -0.83 \text{ V}$
- Water-oxidation half-reaction:  
 $2\text{H}_2\text{O}(l) \longrightarrow \text{O}_2(g) + 4\text{H}^+(aq) + 4\text{e}^-;$   
 $-E^\circ = -1.23 \text{ V}$
- Aqueous electrolysis
- Electrolysis
- Standard electrode potential
- Half-reaction

Because the copper electrode potential is much larger than the reduction potential of water, you expect  $\text{Cu}^{2+}$  to be reduced.

Possible anode half-reactions, with the signs reversed for the electrode potentials, are

You expect  $\text{H}_2\text{O}$  to be oxidized.

The expected half-reactions are

**Answer Check** For aqueous electrolysis, always make sure that you consider the possibility of water undergoing oxidation at the anode or reduction at the cathode.

**Exercise 19.16** Give the half-reactions that occur when aqueous silver nitrate is electrolyzed. Nitrate ion is not oxidized during the electrolysis.

See Problems 19.93 and 19.94.

**19.11 Stoichiometry of Electrolysis**

In 1831 and 1832, the British chemist and physicist Michael Faraday showed that the amounts of substances released at the electrodes during electrolysis are related to the total charge that has flowed in the electric circuit. ▶ If you look at the electrode reactions, you see that the relationship is stoichiometric.

When molten sodium chloride is electrolyzed, sodium ions migrate to the cathode, where they react with electrons.

Similarly, chloride ions migrate to the anode and release electrons.

Therefore, when one mole of electrons reacts with sodium ions, one faraday of charge (the magnitude of charge on one mole of electrons) passes through the circuit. One mole of sodium metal is deposited at one electrode, and one-half mole of chlorine gas evolves at the other electrode.

What is new in this type of stoichiometric problem is the measurement of numbers of electrons. You do not weigh them as you do substances. Rather, you measure the quantity of electric charge that has passed through the circuit. You use the following fact:

One faraday ( $9.6485 \times 10^4 \text{ C}$ ) is equivalent to the charge on one mole of electrons.

If you know the current in a circuit and the length of time it has been flowing, you can calculate the electric charge.

$$\text{Electric charge} = \text{electric current} \times \text{time lapse}$$

Corresponding units are

$$\text{Coulombs} = \text{amperes} \times \text{seconds}$$

The **ampere (A)** is the base unit of current in the International System (SI). The coulomb (C), the SI unit of electric charge, is equivalent to an ampere-second. Thus, a current of 0.50 amperes flowing for 84 seconds gives a charge of  $0.50 \text{ A} \times 84 \text{ s} = 42 \text{ A} \cdot \text{s}$ , or 42 C.

Faraday's results were summarized in two laws: (1) The quantity of a substance liberated at an electrode is directly proportional to the quantity of electric charge that has flowed in the circuit. (2) For a given quantity of electric charge, the amount of any metal deposited is proportional to its equivalent mass (atomic weight divided by the charge on the metal ion). These laws follow directly from the stoichiometry of electrolysis.

If you are given the amount of substance produced at an electrode and the time of electrolysis, you can determine the current. If you are given the current and the time of electrolysis, you can calculate the amount of substance produced at an electrode. The next two examples illustrate these calculations.

### Example 19.14 Calculating the Amount of Charge from the Amount of Product in an Electrolysis

#### Gaining Mastery Toolbox

##### Critical Concept 19.14

The faraday ( $9.6485 \times 10^4 \text{ C}$ ) is a conversion factor that relates a mole of electrons to its charge. The SI unit of charge is the coulomb (C), and an ampere (A) is the SI unit of current.

##### Solution Essentials:

- Charge, current, and time relationship ( $C = A \times \text{sec}$ )
- Ampere (A)
- Coulomb (C)
- Faraday ( $9.6485 \times 10^4 \text{ C}$ ), the charge on one mole of electrons
- Aqueous electrolysis
- Electrolysis
- Half-reaction

When an aqueous solution of copper(II) sulfate,  $\text{CuSO}_4$ , is electrolyzed, copper metal is deposited.

(The other electrode reaction gives oxygen:  $2\text{H}_2\text{O} \longrightarrow \text{O}_2 + 4\text{H}^+ + 4\text{e}^-$ .) If a constant current was passed for 5.00 h and 404 mg of copper metal was deposited, what was the current?

**Problem Strategy** The electrode equation for copper says that 1 mol Cu is equivalent to 2 mol  $\text{e}^-$ . You can use this in the conversion of grams of Cu to moles of electrons needed to deposit this amount of copper. The Faraday constant (which says that one mole of electrons is equivalent to  $9.6485 \times 10^4 \text{ C}$ ) converts moles of electrons to coulombs.

Diagramming the solution clearly shows how three conversion factors (3  $\Rightarrow$ ) are used to solve the problem.

The current in amperes (A) equals the charge in coulombs divided by the time in seconds.

**Solution** The conversion of grams of Cu to coulombs required to deposit 404 mg of copper is

$$0.404 \text{ g Cu} \times \frac{1 \text{ mol Cu}}{63.6 \text{ g Cu}} \times \frac{2 \text{ mol e}^-}{1 \text{ mol Cu}} \times \frac{9.6485 \times 10^4 \text{ C}}{1 \text{ mol e}^-} = 1.226 \times 10^3 \text{ C}$$

The time lapse, 5.00 h, equals  $1.80 \times 10^4 \text{ s}$ . Thus,

$$\text{Current} = \frac{\text{charge}}{\text{time}} = \frac{1.226 \times 10^3 \text{ C}}{1.80 \times 10^4 \text{ s}} = 6.81 \times 10^{-2} \text{ A}$$

**Answer Check** A common mistake that you want to avoid when you work this type of problem is thinking that the coulomb (C) is the current. Therefore, always make sure that when a problem asks for the current, you convert from coulombs to amps (A).

**Exercise 19.17** A constant electric current deposits 365 mg of silver in 216 min from an aqueous silver nitrate solution. What is the current?

See Problems 19.95 and 19.96.

### Example 19.15 Calculating the Amount of Product from the Amount of Charge in an Electrolysis

#### Gaining Mastery Toolbox

##### Critical Concept 19.15

The faraday ( $9.6485 \times 10^4 \text{ C}$ ) is a conversion factor that relates a mole of electrons to its charge. The SI unit of charge is the coulomb (C), and an ampere (A) is the SI unit of current.

When an aqueous solution of potassium iodide is electrolyzed using platinum electrodes, the half-reactions are

How many grams of iodine are produced when a current of 8.52 mA flows through the cell for 10.0 min?

(continued)

**Example 19.15** (continued)**Solution Essentials:**

- Charge, current, and time relationship ( $C = A \times \text{sec}$ )
- Ampere (A)
- Coulomb (C)
- Faraday ( $9.6485 \times 10^4 \text{ C}$ ), the charge on one mole of electrons
- Electrolysis
- Half-reaction

**Problem Strategy** The current in amperes multiplied by the time in seconds equals the charge in coulombs. Convert the charge in coulombs to moles of electrons. Then, noting that each mole of iodine produced requires  $2 \text{ mol e}^-$ , convert  $\text{mol e}^-$  to  $\text{mol I}_2$ . Finally, convert  $\text{mol I}_2$  to  $\text{g I}_2$ .

Diagramming the solution clearly shows how three conversion factors (3  $\Rightarrow$ ) are used to solve the problem.

Note that two moles of electrons are equivalent to one mole of  $\text{I}_2$ .

**Solution** When the current flows for  $6.00 \times 10^2 \text{ s}$  (10.0 min), the amount of charge is

$$8.52 \times 10^{-3} \text{ A} \times 6.00 \times 10^2 \text{ s} = 5.11 \text{ C}$$

$$5.11 \text{ C} \times \frac{1 \text{ mol e}^-}{9.6485 \times 10^4 \text{ C}} \times \frac{1 \text{ mol I}_2}{2 \text{ mol e}^-} \times \frac{254 \text{ g I}_2}{1 \text{ mol I}_2} = 6.73 \times 10^{-3} \text{ g I}_2$$

**Answer Check** It is wise to see whether the calculated amount of material deposited during electrolysis is consistent with the amount and duration of the current. In this problem, where a small amount of current (8.52 mA) flows for a short period of time (10.0 min), we should not expect a large mass of product ( $\text{I}_2$ ) to be deposited.

**Exercise 19.18** How many grams of oxygen are liberated by the electrolysis of water with a current of  $0.0565 \text{ A}$  after  $1.85 \times 10^4 \text{ s}$ ? See Problems 19.97 and 19.98.

## A Checklist for Review

### Summary of Facts and Concepts

*Oxidation–reduction reactions* involve a transfer of electrons from one species to another. The *half-reaction method* can be applied to balancing oxidation–reduction reactions in acidic and basic solutions. Many of the principles required for balancing these reactions were presented in Chapter 4.

Electrochemical cells are of two types: voltaic and electrolytic. A *voltaic cell* uses a spontaneous chemical reaction to generate an electric current. It does this by physically separating the reaction into its oxidation and reduction half-reactions. These half-reactions take place in *half-cells*. The half-cell in which reduction occurs is called the *cathode*; the half-cell in which oxidation occurs is called the *anode*. Electrons flow in the external circuit from the anode to the cathode.

The *cell potential* is the maximum voltage of a voltaic cell. It can be directly related to the maximum work that can be done by the cell. A *standard electrode potential*, or reduction potential, refers to the potential of an electrode in which molar concentrations and gas pressures (in atmospheres) have unit values. A table of standard electrode potentials is useful for establishing the direction of spontaneity of an oxidation–reduction reaction and for calculating the *standard cell potential* of a cell.

The standard free-energy change, standard cell potential, and equilibrium constant are all related. Knowing one, you can calculate the others. Electrochemical measurements can therefore provide equilibrium or thermodynamic information.

An electrode potential depends on concentrations of the electrode substances, according to the *Nernst equation*. Because of this relationship, cell potentials can be used to measure ion concentrations. This is the basic principle of a pH meter, a device that measures the hydrogen-ion concentration.

Voltaic cells are used commercially as portable energy sources (batteries). In addition, the basic principle of the voltaic cell is employed in the *cathodic protection* of buried pipelines and tanks.

*Electrolytic cells* represent another type of electrochemical cell. They use an external voltage source to push a reaction in a nonspontaneous direction. The electrolysis of an aqueous solution often involves the oxidation or reduction of water at the electrodes. Electrolysis of concentrated sodium chloride solution, for example, gives hydrogen at the cathode. The amounts of substances released at an electrode are related to the amount of charge passed through the cell. This relationship is stoichiometric and follows from the electrode reactions.

**19.8 Some Commercial Voltaic Cells**

- Describe the construction and reactions of a *zinc–carbon dry cell*, a *lithium–iodine battery*, a *lead storage cell*, and a *nickel–cadmium cell*.
- Explain the operation of a proton-exchange membrane *fuel cell*.
- Explain the electrochemical process of the rusting of iron.
- Define *cathodic protection*.

**zinc–carbon (Leclanché) dry cell**  
**alkaline dry cell**  
**lithium–iodine battery**  
**lead storage cell**  
**nickel–cadmium cell**  
**fuel cell**

**19.9 Electrolysis of Molten Salts**

- Define *electrolysis*.

**electrolysis**  
**Downs cell**

**19.10 Aqueous Electrolysis**

- Learn the half-reactions for water undergoing oxidation and reduction.
- Predict the half-reactions in an aqueous electrolysis.  
**Example 19.13**

**chlor-alkali membrane cell**  
**chlor-alkali mercury cell**

**19.11 Stoichiometry of Electrolysis**

- Calculate the amount of charge from the amount of product in an electrolysis. **Example 19.14**
- Calculate the amount of product from the amount of charge in an electrolysis. **Example 19.15**

**ampere (A)**

**Key Equations**

$$w_{\max} = -nFE_{\text{cell}}$$

$$E_{\text{cell}}^{\circ} = E_{\text{cathode}}^{\circ} - E_{\text{anode}}^{\circ}$$

$$\Delta G^{\circ} = -nFE_{\text{cell}}^{\circ}$$

$$E_{\text{cell}}^{\circ} = \frac{0.0592}{n} \log K \quad (\text{values in volts at } 25^{\circ}\text{C})$$

$$E_{\text{cell}} = E_{\text{cell}}^{\circ} - \frac{0.0592}{n} \log Q \quad (\text{values in volts at } 25^{\circ}\text{C})$$

**Questions and Problems****Self-Assessment and Review Questions**

**Key:** These questions test your understanding of the ideas you worked with in the chapter. These problems vary in difficulty and often can be used for the basis of discussion.

**19.1** Describe the difference between a voltaic cell and an electrolytic cell.

**19.2** Define *cathode* and *anode*.

**19.3** What is the SI unit of electrical potential?

**19.4** Define the *faraday*.

**19.5** Why is it necessary to measure the voltage of a voltaic cell when no current is flowing to obtain the cell potential?

**19.6** How are standard electrode potentials defined?

**19.7** Express the SI unit of energy as the product of two electrical units.

**19.8** Give the mathematical relationships between the members of each possible pair of the three quantities  $\Delta G^{\circ}$ ,  $E_{\text{cell}}^{\circ}$ , and  $K$ .

**19.9** Using the Nernst equation, explain how the corrosion of iron would be affected by the pH of a water drop.

**19.10** Describe the zinc–carbon, or Leclanché, dry cell and the lead storage battery.

**19.11** What is a fuel cell? Describe an example.

**19.12** Explain the electrochemistry of rusting.

**19.13** Iron may be protected by coating with tin (tin cans) or with zinc (galvanized iron). Galvanized iron does not corrode as long as zinc is present. By contrast, when a tin can is scratched, the exposed iron underneath corrodes rapidly. Explain the difference between zinc and tin as protective coatings against iron corrosion.

**19.14** The electrolysis of water is often done by passing a current through a dilute solution of sulfuric acid. What is the function of the sulfuric acid?

**19.15** Describe a method for the preparation of sodium metal from sodium chloride.

**19.16** Potassium was discovered by the British chemist Humphry Davy when he electrolyzed molten potassium hydroxide. What would be the anode reaction?

**19.17** Briefly explain why different products are obtained from the electrolysis of molten NaCl and the electrolysis of a dilute aqueous solution of NaCl.

**19.18** Write the Nernst equation for the electrode reaction  $2\text{Cl}^{-}(\text{aq}) \longrightarrow \text{Cl}_2(\text{g}) + 2\text{e}^{-}$ . With this equation, explain why the electrolysis of concentrated sodium chloride solution might be expected to release chlorine gas rather than oxygen gas at the anode.

**19.19** The following oxidation–reduction reaction occurs in acidic solution. When the equation is balanced using the smallest set of whole-number stoichiometric coefficients possible, what is the stoichiometric coefficient for water? (*Hint:* In addition to the species shown in the original equation,  $\text{H}^+(\text{aq})$  and  $\text{H}_2\text{O}(\text{l})$  can also appear in the balanced equation.)

- a** 13    **b** 19    **c** 11    **d** 7    **e** 4

**19.20** What half-reaction would be expected to occur at the cathode in the electrolysis of aqueous sodium fluoride?

- a**  $2\text{F}^-(\text{aq}) \longrightarrow \text{F}_2(\text{g}) + 2\text{e}^-$   
**b**  $2\text{H}_2\text{O}(\text{l}) \longrightarrow \text{O}_2(\text{g}) + 4\text{H}^+(\text{aq}) + 4\text{e}^-$   
**c**  $2\text{H}_2\text{O}(\text{l}) + 2\text{e}^- \longrightarrow \text{H}_2(\text{g}) + 2\text{OH}^-(\text{aq})$   
**d**  $\text{Na}^+(\text{aq}) + \text{e}^- \longrightarrow \text{Na}(\text{s})$   
**e**  $\text{NaF}(\text{aq}) \longrightarrow \text{NaF}(\text{s})$

**19.21** Electrolysis of an aqueous solution of sodium chloride produces chlorine,  $\text{Cl}_2(\text{g})$ . The reaction that occurs at the anode is

A constant electric current produces 152 g  $\text{Cl}_2$  in 56.1 min from an aqueous solution of sodium chloride. What is the current?

- a** 123 A    **b** 61.5 A    **c** 30.7 A  
**d**  $6.18 \times 10^5$  A    **e**  $4.36 \times 10^3$  A

**19.22** The voltaic cell is represented as

Which of the following statements is *not* true of this cell?

- a** The mass of the zinc electrode,  $\text{Zn}(\text{s})$ , decreases as the cell runs.  
**b** The copper electrode is the anode.  
**c** Electrons flow through the external circuit from the zinc electrode to the copper electrode.  
**d** Reduction occurs at the copper electrode as the cell runs.  
**e** The concentration of  $\text{Cu}^{2+}$  decreases as the cell runs.

## Concept Explorations

**Key:** Concept explorations are comprehensive problems that provide a framework that will enable you to explore and learn many of the critical concepts and ideas in each chapter. If you master the concepts associated with these explorations, you will have a better understanding of many important chemistry ideas and will be more successful in solving all types of chemistry problems. These problems are well suited for group work and for use as in-class activities.

### 19.23 Electrochemical Cells I

You have the following setup to construct a cell under standard conditions. The anode and cathode are iron and silver rods. Using cell notation, the cell is

- a** Complete the figure of the cell by labeling the anode and cathode and showing the corresponding reactions at the electrodes. Indicate the electron flow in the external circuit, the signs of the electrodes, and the direction of cation migration in the half-cells.  
**b** What is the cell potential,  $E_{\text{cell}}^\circ$ ? Is this a voltaic or an electrolytic cell? How do you know?  
**c** You send your lab partner to find the solutions for the beakers. What would you tell him to look for? Provide specific examples of solutions as part of your answer.

- d** When you are constructing the cell, what impact does the volume of solution in each of the beakers have on the cell potential? (Assume that there is enough volume to cover at least one-third of the anode and cathode rods.)  
**e** If you were to add deionized (distilled) water to the solution that contains the  $\text{Ag}^+(\text{aq})$ , would this have any effect on the cell voltage? If so, explain how the cell voltage would change.  
**f** When constructing the cell, you decide to swap the silver rod that is used as an anode for a copper rod,  $\text{Cu}(\text{s})$ . Will this change have any effect on the cell potential or the operation of the cell? Explain.  
**g** Starting with the original cell, this time you swap the iron rod used as the anode for a copper rod,  $\text{Cu}(\text{s})$ . How will this change affect the cell potential and the operation of the cell?

### 19.24 Electrochemical Cells II

Consider this cell running under standard conditions:

- a** Is this cell a voltaic or an electrolytic cell? How do you know?  
**b** Does current flow in this cell spontaneously?  
**c** What is the maximum cell potential for this cell?  
**d** Say the cell is connected to a voltmeter. Describe what you might see for an initial voltage and what voltage changes, if any, you would observe as time went by.  
**e** What is the free energy of this cell when it is first constructed?  
**f** Does the free energy of the cell change over time as the cell runs? If so, how does it change?

## Conceptual Problems

**Key:** These problems are designed to check your understanding of the concepts associated with some of the main topics presented in each chapter. A strong conceptual understanding of chemistry is the foundation for both applying chemical knowledge and solving chemical problems. These problems vary in level of difficulty and often can be used as a basis for group discussion.

**19.25** Keeping in mind that aqueous  $\text{Cu}^{2+}$  is blue and aqueous  $\text{Zn}^{2+}$  is colorless, predict what you would observe over a several-day period if you performed the following experiments.

- A strip of Zn is placed into a beaker containing aqueous  $\text{Zn}^{2+}$ .
- A strip of Cu is placed into a beaker containing aqueous  $\text{Cu}^{2+}$ .
- A strip of Zn is placed into a beaker containing aqueous  $\text{Cu}^{2+}$ .
- A strip of Cu is placed into a beaker containing aqueous  $\text{Zn}^{2+}$ .

**19.26** You are working at a plant that manufactures batteries. A client comes to you and asks for a 6.0-V battery that is made from silver and cadmium. Assuming that you are running the battery under standard conditions, how should it be constructed?

**19.27** The composition of the hull of a submarine is mostly iron. Pieces of zinc, called “zincs,” are placed in contact with the hull throughout the inside of the submarine. Why is this done?

**19.28** You place a battery in a flashlight in which all of the electrochemical reactions have reached equilibrium. What do you expect to observe when you turn on the flashlight? Explain your answer.

**19.29** The difference between a “heavy-duty” and a regular zinc–carbon battery is that the zinc can in the heavy-duty battery has thicker walls. What makes this battery heavy-duty in terms of output?

**19.30** From an electrochemical standpoint, what metal, other than zinc, would be a reasonable candidate to coat a piece of iron to prevent corrosion (oxidation)?

**19.31** Pick a combination of two metals from the Standard Reduction Potential table (Table 19.1 or Appendix I) that would result in a cell with a potential of about +0.90 V. For your answer, write both the half-reactions, write the overall balanced reaction, and calculate the cell potential for your choice.

**19.32** You have 1.0 M solutions of  $\text{Al}(\text{NO}_3)_3$  and  $\text{AgNO}_3$  along with Al and Ag electrodes to construct a voltaic cell. The salt bridge contains a saturated solution of KCl. Complete the picture associated with this problem by

- writing the symbols of the elements and ions in the appropriate areas (both solutions and electrodes).
- identifying the anode and cathode.
- indicating the direction of electron flow through the external circuit.
- indicating the cell potential (assume standard conditions, with no current flowing).
- writing the appropriate half-reaction under each of the containers.
- indicating the direction of ion flow in the salt bridge.

- identifying the species undergoing oxidation and reduction.
- writing the balanced overall reaction for the cell.

**19.33** The zinc–copper voltaic cell shown with this problem is currently running under standard conditions. How would the intensity of light from the bulb change if you were to

- dissolve some additional  $\text{CuSO}_4(s)$  in the  $\text{CuSO}_4$  solution?
- dissolve some additional  $\text{Zn}(\text{NO}_3)_2(s)$  in the  $\text{Zn}(\text{NO}_3)_2$  solution?
- add  $\text{H}_2\text{O}$  to the  $\text{CuSO}_4$  solution?
- remove the salt bridge?

**19.34** The development of lightweight batteries is an ongoing research effort combining many of the physical sciences. You are a member of an engineering team trying to develop a lightweight battery that will effectively react with  $\text{O}_2(g)$  from the atmosphere as an oxidizing agent. A reducing agent must be chosen for this battery that will be lightweight, have nontoxic products, and react spontaneously with oxygen. Using data from Appendix I, suggest a likely reducing agent, being sure these conditions are met. Are there any drawbacks to your selection?

## Practice Problems

**Key:** These problems are for practice in applying problem-solving skills. They are divided by topic, and some are keyed to exercises (see the ends of the exercises). The problems are arranged in matching pairs; the odd-numbered problem of each pair is listed first, and its answer is given in the back of the book.

### Balancing Oxidation–Reduction Equations

**19.35** Balance the following oxidation–reduction equations. The reactions occur in acidic solution.

- a  $\text{Cr}_2\text{O}_7^{2-} + \text{C}_2\text{O}_4^{2-} \longrightarrow \text{Cr}^{3+} + \text{CO}_2$
- b  $\text{Cu} + \text{NO}_3^- \longrightarrow \text{Cu}^{2+} + \text{NO}$
- c  $\text{MnO}_2 + \text{HNO}_2 \longrightarrow \text{Mn}^{2+} + \text{NO}_3^-$
- d  $\text{PbO}_2 + \text{Mn}^{2+} + \text{SO}_4^{2-} \longrightarrow \text{PbSO}_4 + \text{MnO}_4^-$
- e  $\text{HNO}_2 + \text{Cr}_2\text{O}_7^{2-} \longrightarrow \text{Cr}^{3+} + \text{NO}_3^-$

**19.36** Balance the following oxidation–reduction equations. The reactions occur in acidic solution.

- a  $\text{Mn}^{2+} + \text{BiO}_3^- \longrightarrow \text{MnO}_4^- + \text{Bi}^{3+}$
- b  $\text{Cr}_2\text{O}_7^{2-} + \text{I}^- \longrightarrow \text{Cr}^{3+} + \text{IO}_3^-$
- c  $\text{MnO}_4^- + \text{H}_2\text{SO}_3 \longrightarrow \text{Mn}^{2+} + \text{SO}_4^{2-}$
- d  $\text{Cr}_2\text{O}_7^{2-} + \text{Fe}^{2+} \longrightarrow \text{Cr}^{3+} + \text{Fe}^{3+}$
- e  $\text{As} + \text{ClO}_3^- \longrightarrow \text{H}_3\text{AsO}_3 + \text{HClO}$

**19.37** Balance the following oxidation–reduction equations. The reactions occur in basic solution.

- a  $\text{Mn}^{2+} + \text{H}_2\text{O}_2 \longrightarrow \text{MnO}_2 + \text{H}_2\text{O}$
- b  $\text{MnO}_4^- + \text{NO}_2^- \longrightarrow \text{MnO}_2 + \text{NO}_3^-$
- c  $\text{Mn}^{2+} + \text{ClO}_3^- \longrightarrow \text{MnO}_2 + \text{ClO}_2$
- d  $\text{MnO}_4^- + \text{NO}_2 \longrightarrow \text{MnO}_2 + \text{NO}_3^-$
- e  $\text{Cl}_2 \longrightarrow \text{Cl}^- + \text{ClO}_3^-$

**19.38** Balance the following oxidation–reduction equations. The reactions occur in basic solution.

- a  $\text{Cr}(\text{OH})_4^- + \text{H}_2\text{O}_2 \longrightarrow \text{CrO}_4^{2-} + \text{H}_2\text{O}$
- b  $\text{MnO}_4^- + \text{Br}^- \longrightarrow \text{MnO}_2 + \text{BrO}_3^-$
- c  $\text{Co}^{2+} + \text{H}_2\text{O}_2 \longrightarrow \text{Co}(\text{OH})_3 + \text{H}_2\text{O}$
- d  $\text{Pb}(\text{OH})_4^{2-} + \text{ClO}^- \longrightarrow \text{PbO}_2 + \text{Cl}^-$
- e  $\text{Zn} + \text{NO}_3^- \longrightarrow \text{NH}_3 + \text{Zn}(\text{OH})_4^{2-}$

**19.39** Balance the following oxidation–reduction equations. The reactions occur in acidic or basic aqueous solution, as indicated.

- a  $\text{H}_2\text{S} + \text{NO}_3^- \longrightarrow \text{NO}_2 + \text{S}_8$  (acidic)
- b  $\text{NO}_3^- + \text{Cu} \longrightarrow \text{NO} + \text{Cu}^{2+}$  (acidic)
- c  $\text{MnO}_4^- + \text{SO}_2 \longrightarrow \text{SO}_4^{2-} + \text{Mn}^{2+}$  (acidic)
- d  $\text{Bi}(\text{OH})_3 + \text{Sn}(\text{OH})_3^- \longrightarrow \text{Sn}(\text{OH})_6^{2-} + \text{Bi}$  (basic)

**19.40** Balance the following oxidation–reduction equations. The reactions occur in acidic or basic aqueous solution, as indicated.

- a  $\text{Hg}_2^{2+} + \text{H}_2\text{S} \longrightarrow \text{Hg} + \text{S}_8$  (acidic)
- b  $\text{S}^{2-} + \text{I}_2 \longrightarrow \text{SO}_4^{2-} + \text{I}^-$  (basic)
- c  $\text{Al} + \text{NO}_3^- \longrightarrow \text{Al}(\text{OH})_4^- + \text{NH}_3$  (basic)
- d  $\text{MnO}_4^- + \text{C}_2\text{O}_4^{2-} \longrightarrow \text{MnO}_2 + \text{CO}_2$  (basic)

**19.41** Balance the following oxidation–reduction equations. The reactions occur in acidic or basic aqueous solution, as indicated.

- a  $\text{MnO}_4^- + \text{I}^- \longrightarrow \text{MnO}_2 + \text{IO}_3^-$  (basic)
- b  $\text{Cr}_2\text{O}_7^{2-} + \text{Cl}^- \longrightarrow \text{Cr}^{3+} + \text{Cl}_2$  (acidic)
- c  $\text{S}_8 + \text{NO}_3^- \longrightarrow \text{SO}_2 + \text{NO}$  (acidic)

- d  $\text{H}_2\text{O}_2 + \text{MnO}_4^- \longrightarrow \text{O}_2 + \text{MnO}_2$  (basic)
- e  $\text{Zn} + \text{NO}_3^- \longrightarrow \text{Zn}^{2+} + \text{N}_2$  (acidic)

**19.42** Balance the following oxidation–reduction equations. The reactions occur in acidic or basic aqueous solution, as indicated.

- a  $\text{Cr}_2\text{O}_7^{2-} + \text{H}_2\text{O}_2 \longrightarrow \text{Cr}^{3+} + \text{O}_2$  (acidic)
- b  $\text{CN}^- + \text{MnO}_4^- \longrightarrow \text{CNO}^- + \text{MnO}_2$  (basic)
- c  $\text{Cr}(\text{OH})_4^- + \text{OCl}^- \longrightarrow \text{CrO}_4^{2-} + \text{Cl}^-$  (basic)
- d  $\text{Br}_2 + \text{SO}_2 \longrightarrow \text{Br}^- + \text{SO}_4^{2-}$  (acidic)
- e  $\text{CuS} + \text{NO}_3^- \longrightarrow \text{Cu}^{2+} + \text{NO} + \text{S}_8$  (acidic)

### Electrochemical Cells

**19.43** A voltaic cell is constructed from the following half-cells: a chromium electrode in chromium(III) sulfate solution and a lead electrode in lead(II) sulfate solution. The half-reactions are

Sketch the cell, labeling the anode and cathode (and the electrode reactions), and show the direction of electron flow and the movement of cations.

**19.44** Half-cells were made from a nickel rod dipping in a nickel sulfate solution and a silver rod dipping in a silver nitrate solution. The half-reactions in a voltaic cell using these half-cells were

Sketch the cell and label the anode and cathode, showing the corresponding electrode reactions. Give the direction of electron flow and the movement of cations.

**19.45** Zinc reacts spontaneously with silver ion.

Describe a voltaic cell using this reaction. What are the half-reactions?

**19.46** Iron reacts spontaneously with copper(II) ion.

Obtain half-reactions for this, and then describe a voltaic cell using these half-reactions.

**19.47** A silver oxide–zinc cell maintains a fairly constant voltage during discharge (1.60 V). The button form of this cell is used in watches, hearing aids, and other electronic devices. The half-reactions are

Identify the anode and the cathode reactions. What is the overall reaction in the voltaic cell?

**19.48** A mercury battery, used for hearing aids and electric watches, delivers a constant voltage (1.35 V) for long periods. The half-reactions are

Which half-reaction occurs at the anode and which occurs at the cathode? What is the overall cell reaction?

### **Voltaic Cell Notation**

**19.49** Write the cell notation for a voltaic cell with the following half-reactions.

**19.50** Write the cell notation for a voltaic cell with the following half-reactions.

**19.51** Give the notation for a voltaic cell constructed from a hydrogen electrode (cathode) in 1.0 *M* HCl and a nickel electrode (anode) in 1.0 *M* NiSO<sub>4</sub> solution. The electrodes are connected by a salt bridge.

**19.52** A voltaic cell has an iron rod in 0.30 *M* iron(III) chloride solution for the cathode and a zinc rod in 0.20 *M* zinc sulfate solution for the anode. The half-cells are connected by a salt bridge. Write the notation for this cell.

**19.53** Write the overall cell reaction for the following voltaic cell.

**19.54** Write the overall cell reaction for the following voltaic cell.

**19.55** Consider the voltaic cell

Write the half-cell reactions and the overall cell reaction. Make a sketch of this cell and label it. Include labels showing the anode, cathode, and direction of electron flow.

**19.56** Consider the voltaic cell

Write the half-cell reactions and the overall cell reaction. Make a sketch of this cell and label it. Include labels showing the anode, cathode, and direction of electron flow.

### **Electrode Potentials and Cell Potentials**

**19.57** A voltaic cell whose cell reaction is

has a cell potential of 0.72 V. What is the maximum electrical work that can be obtained from this cell per mole of iron(III) ion?

**19.58** A particular voltaic cell operates on the reaction

giving a cell potential of 0.853 V. Calculate the maximum electrical work generated when 15.0 g of zinc metal is consumed.

**19.59** What is the maximum work you can obtain from 30.0 g of nickel in the following cell when the cell potential is 0.97 V?

**19.60** Calculate the maximum work available from 50.0 g of aluminum in the following cell when the cell potential is 1.15 V.

Note that O<sub>2</sub> is reduced to H<sub>2</sub>O.

**19.61** Order the following oxidizing agents by increasing strength under standard-state conditions: O<sub>2</sub>(g); MnO<sub>4</sub><sup>-</sup>(aq); NO<sub>3</sub><sup>-</sup>(aq) (in acidic solution).

**19.62** Order the following oxidizing agents by increasing strength under standard-state conditions: Ag<sup>+</sup>(aq); Cd<sup>2+</sup>(aq); MnO<sub>4</sub><sup>-</sup>(aq) (in acidic solution).

**19.63** Consider the reducing agents Cu<sup>+</sup>(aq), Zn(s), and Fe(s). Which is strongest? Which is weakest?

**19.64** Consider the reducing agents Sn<sup>2+</sup>(aq), Cl<sub>2</sub>(g), and I<sup>-</sup>(aq). Which is strongest? Which is weakest?

**19.65** Consider the following reactions. Are they spontaneous in the direction written, under standard conditions at 25°C?

**19.66** Answer the following questions by referring to standard electrode potentials at 25°C.

**a** Will oxygen, O<sub>2</sub>, oxidize iron(II) ion in solution under standard conditions?

**b** Will copper metal reduce 1.0 *M* Ni<sup>2+</sup>(aq) to metallic nickel?

**19.67** What would you expect to happen when chlorine gas, Cl<sub>2</sub>, at 1 atm pressure is bubbled into a solution containing 1.0 *M* F<sup>-</sup> and 1.0 *M* Br<sup>-</sup> at 25°C? Write a balanced equation for the reaction that occurs.

**19.68** Dichromate ion, Cr<sub>2</sub>O<sub>7</sub><sup>2-</sup>, is added to an acidic solution containing Br<sup>-</sup> and Mn<sup>2+</sup>. Write a balanced equation for any reaction that occurs. Assume standard conditions at 25°C.

**19.69** Calculate the standard cell potential of the following cell at 25°C.

**19.70** Calculate the standard cell potential of the following cell at 25°C.

**19.71** What is the standard cell potential you would obtain from a cell at 25°C using an electrode in which I<sup>-</sup>(aq) is in contact with I<sub>2</sub>(s) and an electrode in which a chromium strip dips into a solution of Cr<sup>3+</sup>(aq)?

**19.72** What is the standard cell potential you would obtain from a cell at 25°C using an electrode in which Hg<sub>2</sub><sup>2+</sup>(aq) is in contact with mercury metal and an electrode in which an aluminum strip dips into a solution of Al<sup>3+</sup>(aq)?

### **Relationships Among $E_{\text{cell}}^{\circ}$ , $\Delta G^{\circ}$ , and $K$**

**19.73** Calculate the standard free-energy change at 25°C for the following reaction.

Use standard electrode potentials.

**19.74** Calculate the standard free-energy change at 25°C for the following reaction.

Use standard electrode potentials.

**19.75** What is  $\Delta G^\circ$  for the following reaction?

Use data given in Table 19.1.

**19.76** Using electrode potentials, calculate the standard free-energy change for the reaction

**19.77** Calculate the standard cell potential at 25°C for the following cell reaction from standard free energies of formation (Appendix C).

**19.78** Calculate the standard cell potential at 25°C for the following cell reaction from standard free energies of formation (Appendix C).

**19.79** Calculate the standard cell potential of the lead storage cell whose overall reaction is

See Appendix C for free energies of formation.

**19.80** Calculate the standard cell potential of the cell corresponding to the oxidation of oxalic acid,  $\text{H}_2\text{C}_2\text{O}_4$ , by permanganate ion,  $\text{MnO}_4^-$ .

See Appendix C for free energies of formation;  $\Delta G_f^\circ$  for  $\text{H}_2\text{C}_2\text{O}_4(aq)$  is  $-698$  kJ.

**19.81** Calculate the equilibrium constant  $K$  for the following reaction at 25°C from standard electrode potentials.

The equation is not balanced.

**19.82** Calculate the equilibrium constant  $K$  for the following reaction at 25°C from standard electrode potentials.

The equation is not balanced.

**19.83** Copper(I) ion can act as both an oxidizing agent and a reducing agent. Hence, it can react with itself.

Calculate the equilibrium constant at 25°C for this reaction, using appropriate values of electrode potentials.

**19.84** Use electrode potentials to calculate the equilibrium constant at 25°C for the reaction

See Appendix I for data.

## Nernst Equation

**19.85** Calculate the cell potential of the following cell at 25°C.

**19.86** What is the cell potential of the following cell at 25°C?

**19.87** Calculate the cell potential of a cell operating with the following reaction at 25°C, in which  $[\text{MnO}_4^-] = 0.010 M$ ,  $[\text{Br}^-] = 0.010 M$ ,  $[\text{Mn}^{2+}] = 0.15 M$ , and  $[\text{H}^+] = 1.0 M$ .

**19.88** Calculate the cell potential of a cell operating with the following reaction at 25°C, in which  $[\text{Cr}_2\text{O}_7^{2-}] = 0.020 M$ ,  $[\text{I}^-] = 0.015 M$ ,  $[\text{Cr}^{3+}] = 0.40 M$ , and  $[\text{H}^+] = 0.60 M$ .

**19.89** The voltaic cell

has a cell potential of 0.290 V at 25°C. What is the concentration of cadmium ion? ( $E^\circ_{\text{cell}} = 0.170$  V.)

**19.90** The cell potential of the following cell at 25°C is 0.480 V.

What is the pH of the test solution?

## Electrolysis

**19.91** What are the half-reactions in the electrolysis of **a**  $\text{CaS}(l)$ ; **b**  $\text{CsOH}(l)$ ?

**19.92** What are the half-reactions in the electrolysis of **a**  $\text{MgBr}_2(l)$ ; **b**  $\text{Ca}(\text{OH})_2(l)$ ?

**19.93** Describe what you expect to happen when the following solutions are electrolyzed: **a** aqueous  $\text{Na}_2\text{SO}_4$ ; **b** aqueous  $\text{KBr}$ . That is, what are the electrode reactions? What is the overall reaction?

**19.94** Describe what you expect to happen when the following solutions are electrolyzed: **a** aqueous  $\text{CuCl}_2$ ; **b** aqueous  $\text{Cu}(\text{NO}_3)_2$ . That is, what are the electrode reactions? What is the overall reaction? Nitrate ion is not reduced.

**19.95** In the commercial preparation of aluminum, aluminum oxide,  $\text{Al}_2\text{O}_3$ , is electrolyzed at 1000°C. (The mineral cryolite is added as a solvent.) Assume that the cathode reaction is

How many coulombs of electricity are required to give 3.09 kg of aluminum?

**19.96** Chlorine,  $\text{Cl}_2$ , is produced commercially by the electrolysis of aqueous sodium chloride. The anode reaction is

How long will it take to produce 2.00 kg of chlorine if the current is  $5.00 \times 10^2$  A?

**19.97** When molten lithium chloride, LiCl, is electrolyzed, lithium metal is liberated at the cathode. How many grams of lithium are liberated when  $2.00 \times 10^3$  C of charge passes through the cell?

**19.98** How many grams of cadmium are deposited from an aqueous solution of cadmium sulfate, CdSO<sub>4</sub>, when an electric current of 1.75 A flows through the solution for 325 min?

## General Problems

**Key:** These problems provide more practice but are not divided by topic or keyed to exercises. Each section ends with essay questions. Odd-numbered problems and the even-numbered problems that follow are similar; answers to all odd-numbered problems except the essay questions are given in the back of the book.

**19.99** Some metals, such as iron, can be oxidized to more than one oxidation state. Obtain the balanced net ionic equations for the following oxidation–reduction reactions, in which nitric acid is reduced to nitric oxide, NO.

- a** Oxidation of iron metal to iron(II) ion by nitric acid.
- b** Oxidation of iron(II) ion to iron(III) ion by nitric acid.
- c** Oxidation of iron metal to iron(III) by nitric acid. [Consider adding the a and b equations.]

**19.100** Some metals, such as thallium, can be oxidized to more than one oxidation state. Obtain the balanced net ionic equations for the following oxidation–reduction reactions, in which nitric acid is reduced to nitric oxide, NO.

- a** Oxidation of thallium metal to thallium(I) ion by nitric acid.
- b** Oxidation of thallium(I) ion to thallium(III) ion by nitric acid.
- c** Oxidation of thallium metal to thallium(III) by nitric acid. [Consider adding the a and b equations.]

**19.101** Balance the following skeleton equations. The reactions occur in acidic or basic aqueous solution, as indicated.

- a**  $\text{MnO}_4^- + \text{S}^{2-} \longrightarrow \text{MnO}_2 + \text{S}_8$  (basic)
- b**  $\text{IO}_3^- + \text{HSO}_3^- \longrightarrow \text{I}^- + \text{SO}_4^{2-}$  (acidic)
- c**  $\text{Fe}(\text{OH})_2 + \text{CrO}_4^{2-} \longrightarrow \text{Fe}(\text{OH})_3 + \text{Cr}(\text{OH})_4^-$  (basic)
- d**  $\text{Cl}_2 \longrightarrow \text{Cl}^- + \text{ClO}^-$  (basic)

**19.102** Balance the following skeleton equations. The reactions occur in acidic or basic aqueous solution, as indicated.

- a**  $\text{MnO}_4^- + \text{H}_2\text{S} \longrightarrow \text{Mn}^{2+} + \text{S}_8$  (acidic)
- b**  $\text{Zn} + \text{NO}_3^- \longrightarrow \text{Zn}^{2+} + \text{N}_2\text{O}$  (acidic)
- c**  $\text{MnO}_4^{2-} \longrightarrow \text{MnO}_4^- + \text{MnO}_2$  (basic)
- d**  $\text{Br}_2 \longrightarrow \text{Br}^- + \text{BrO}_3^-$  (basic)

**19.103** Iron(II) hydroxide is a greenish precipitate that is formed from iron(II) ion by the addition of a base. This precipitate gradually turns to the yellowish-brown iron(III) hydroxide from oxidation by O<sub>2</sub> in the air. Write a balanced equation for this oxidation by O<sub>2</sub>.

**19.104** A sensitive test for bismuth(III) ion consists of shaking a solution suspected of containing the ion with a basic solution of sodium stannite, Na<sub>2</sub>SnO<sub>2</sub>. A positive test consists of the formation of a black precipitate of bismuth metal. Stannite ion is oxidized by bismuth(III) ion to stannate ion, SnO<sub>3</sub><sup>2-</sup>. Write a balanced equation for the reaction.

**19.105** Give the notation for a voltaic cell that uses the reaction

What is the half-cell reaction for the anode? for the cathode? What is the standard cell potential of the cell?

**19.106** Give the notation for a voltaic cell whose overall cell reaction is

What are the half-cell reactions? Label them as anode or cathode reactions. What is the standard cell potential of this cell?

**19.107** Use electrode potentials to answer the following questions. **a** Is the oxidation of nickel by iron(III) ion a spontaneous reaction under standard conditions?

**b** Will iron(III) ion oxidize tin(II) ion to tin(IV) ion under standard conditions?

**19.108** Use electrode potentials to answer the following questions, assuming standard conditions. **a** Do you expect permanganate ion (MnO<sub>4</sub><sup>-</sup>) to oxidize chloride ion to chlorine gas in acidic solution? **b** Will dichromate ion (Cr<sub>2</sub>O<sub>7</sub><sup>2-</sup>) oxidize chloride ion to chlorine gas in acidic solution?

**19.109** Determine the cell potential of the following cell.

The anode is essentially a lead electrode, Pb|Pb<sup>2+</sup>(aq). However, the anode solution is saturated with lead sulfate, so that the lead(II)-ion concentration is determined by the solubility product of PbSO<sub>4</sub> ( $K_{sp} = 1.7 \times 10^{-8}$ ).

**19.110** Determine the cell potential of the following cell.

The cathode is essentially a silver electrode, Ag<sup>+</sup>(aq)|Ag. However, the cathode solution is saturated with silver chloride, so that the silver-ion concentration is determined by the solubility product of AgCl ( $K_{sp} = 1.8 \times 10^{-10}$ ).

**19.111** **a** Calculate the equilibrium constant for the following reaction at 25°C.

The standard cell potential of the corresponding voltaic cell is 0.010 V. **b** If an excess of tin metal is added to 1.0 M Pb<sup>2+</sup>, what is the concentration of Pb<sup>2+</sup> at equilibrium?

**19.112** **a** Calculate the equilibrium constant for the following reaction at 25°C.

The standard cell potential of the corresponding voltaic cell is 0.030 V. **b** When equal volumes of 0.75 *M* solutions of  $\text{Ag}^+$  and  $\text{Fe}^{2+}$  are mixed, what is the equilibrium concentration of  $\text{Fe}^{2+}$ ?

**19.113** How many faradays are required for each of the following processes? How many coulombs are required?

- a** Reduction of 5.0 mol  $\text{Na}^+$  to Na
- b** Reduction of 5.0 mol  $\text{Cu}^{2+}$  to Cu
- c** Oxidation of 6.0 g  $\text{H}_2\text{O}$  to  $\text{O}_2$
- d** Oxidation of 6.0 g  $\text{Cl}^-$  to  $\text{Cl}_2$

**19.114** How many faradays are required for each of the following processes? How many coulombs are required?

- a** Reduction of 2.0 mol  $\text{Fe}^{3+}$  to  $\text{Fe}^{2+}$
- b** Reduction of 2.0 mol  $\text{Fe}^{3+}$  to Fe
- c** Oxidation of 2.5 g  $\text{Sn}^{2+}$  to  $\text{Sn}^{4+}$
- d** Reduction of 2.5 g  $\text{Au}^{3+}$  to Au

**19.115** In an analytical determination of arsenic, a solution containing arsenious acid,  $\text{H}_3\text{AsO}_3$ , potassium iodide, and a small amount of starch is electrolyzed. The electrolysis produces free iodine from iodide ion, and the iodine immediately oxidizes the arsenious acid to hydrogen arsenate ion,  $\text{HAsO}_4^{2-}$ .

When the oxidation of arsenic is complete, the free iodine combines with the starch to give a deep blue color. If, during a particular run, it takes 65.4 s for a current of 10.5 mA to give an endpoint (indicated by the blue color), how many grams of arsenic are present in the solution?

**19.116** The amount of lactic acid,  $\text{HC}_3\text{H}_5\text{O}_3$ , produced in a sample of muscle tissue was analyzed by reaction with hydroxide ion. Hydroxide ion was produced in the sample mixture by electrolysis. The cathode reaction was

Hydroxide ion reacts with lactic acid as soon as it is produced. The endpoint of the reaction is detected with an acid–base indicator. It required 105 s for a current of 15.6 mA to reach the endpoint. How many grams of lactic acid (a monoprotic acid) were present in the sample?

**19.117** A standard electrochemical cell is made by dipping a silver electrode into a 1.0 *M*  $\text{Ag}^+$  solution and a cadmium electrode into a 1.0 *M*  $\text{Cd}^{2+}$  solution.

- a** What is the spontaneous chemical reaction, and what is the maximum potential produced by this cell?
- b** What would be the effect on the potential of this cell if sodium sulfide were added to the  $\text{Cd}^{2+}$  half-cell and  $\text{CdS}$  were precipitated? Why?
- c** What would be the effect on the potential of the cell if the size of the silver electrode were doubled?

**19.118** A standard electrochemical cell is made by dipping an iron electrode into a 1.0 *M*  $\text{Fe}^{2+}$  solution and a copper electrode into a 1.0 *M*  $\text{Cu}^{2+}$  solution.

- a** What is the spontaneous chemical reaction, and what is the maximum potential produced by this cell?
- b** What would be the effect on the potential of this cell if sodium carbonate were added to the  $\text{Cu}^{2+}$  half-cell and  $\text{CuCO}_3$  were precipitated? Why?
- c** What would be the effect on the potential of the cell if the size of the iron electrode were halved?

**19.119** A solution of copper(II) sulfate is electrolyzed by passing a current through the solution using inert electrodes. Consequently, there is a decrease in the  $\text{Cu}^{2+}$  concentration and an increase in the hydronium ion concentration. Also, one electrode increases in mass and a gas evolves at the other electrode. Write half-reactions that occur at the anode and at the cathode.

**19.120** A potassium chloride solution is electrolyzed by passing a current through the solution using inert electrodes. A gas evolves at each electrode, and there is a large increase in pH of the solution. Write the half-reactions that occur at the anode and at the cathode.

**19.121** A constant current of 1.40 amp is passed through an electrolytic cell containing a 0.100 *M* solution of  $\text{AgNO}_3$  and a silver anode and a platinum cathode until 2.48 g of silver is deposited.

- a** How long does the current flow to obtain this deposit?
- b** What mass of chromium would be deposited in a similar cell containing 0.100 *M*  $\text{Cr}^{3+}$  if the same amount of current were used?

**19.122** A constant current of 1.25 amp is passed through an electrolytic cell containing a 0.050 *M* solution of  $\text{CuSO}_4$  and a copper anode and a platinum cathode until 3.00 g of copper is deposited.

- a** How long does the current flow to obtain this deposit?
- b** What mass of silver would be deposited in a similar cell containing 0.15 *M*  $\text{Ag}^+$  if the same amount of current were used?

**19.123** An aqueous solution of an unknown salt of gold is electrolyzed by a current of 2.75 amps for 3.39 hours. The electroplating is carried out with an efficiency of 93.0%, resulting in a deposit of 21.221 g of gold.

- a** How many faradays are required to deposit the gold?
- b** What is the charge on the gold ions (based on your calculations)?

**19.124** An aqueous solution of an unknown salt of vanadium is electrolyzed by a current of 2.50 amps for 1.90 hours. The electroplating is carried out with an efficiency of 95.0%, resulting in a deposit of 2.850 g of vanadium.

- a** How many faradays are required to deposit the vanadium?
- b** What is the charge on the vanadium ions (based on your calculations)?

**19.125** An electrochemical cell is made by placing a zinc electrode in 1.00 L of 0.200 *M*  $\text{ZnSO}_4$  solution and a copper electrode in 1.00 L of 0.0100 *M*  $\text{CuCl}_2$  solution.

- a** What is the initial voltage of this cell when it is properly constructed?
- b** Calculate the final concentration of  $\text{Cu}^{2+}$  in this cell if it is allowed to produce an average current of 1.00 amp for 225 s.

**19.126** An electrochemical cell is made by placing an iron electrode in 1.00 L of 0.15 *M*  $\text{FeSO}_4$  solution and a copper electrode in 1.00 L of 0.040 *M*  $\text{CuSO}_4$  solution.

- a** What is the initial voltage of this cell when it is properly constructed?
- b** Calculate the final concentration of  $\text{Cu}^{2+}$  in this cell if it is allowed to produce an average current of 1.25 amp for 375 s.

**19.127 a** Calculate  $\Delta G^\circ$  for the following cell reaction:

The  $\Delta G_f^\circ$  for  $\text{Cd}^{2+}(aq)$  is  $-77.6$  kJ/mol.

**b** From  $\Delta G^\circ$ , calculate the standard cell potential for the cell reaction and from this, determine the standard potential for  $\text{Co}^{2+}(aq) + 2e^- \longrightarrow \text{Co}(s)$ .

**19.128 a** Calculate  $\Delta G^\circ$  for the following cell reaction:

The  $\Delta G_f^\circ$  for  $\text{Tl}^+(aq)$  is  $-32.4$  kJ/mol.

**b** From  $\Delta G^\circ$ , calculate the standard cell potential for the cell reaction and from this, determine the standard potential for  $\text{Tl}^+(aq) + e^- \longrightarrow \text{Tl}(s)$ .

**19.129** What is the anode material (during discharge) for a common lithium-ion battery? What is the cathode material for this battery?

**19.130** Why are lithium-ion batteries especially desirable for portable devices like cell phones?

## Strategy Problems

**Key:** As noted earlier, all of the practice and general problems are matched pairs. This section is a selection of problems that are not in matched-pair format. These challenging problems require that you employ many of the concepts and strategies that were developed in the chapter. In some cases, you will have to integrate several concepts and operational skills in order to solve the problem successfully.

**19.131** A voltaic cell is constructed from a half-cell in which a chromium rod dips into a solution of chromium(III) nitrate,  $\text{Cr}(\text{NO}_3)_3$ , and another half-cell in which a lead rod dips into a solution of lead(II) nitrate,  $\text{Pb}(\text{NO}_3)_2$ . The two half-cells are connected by a salt bridge. Chromium metal is oxidized during operation of the voltaic cell. What is the half-reaction that occurs at the cathode?

**19.132** What are the overall cell reaction and the cell potential for this voltaic cell?

**19.133** The cell potential of a particular voltaic cell with the cell reaction

is 1.14 V. What is the maximum electrical work, per mole, that can be obtained from 6.61 g of chromium metal?

**19.134** Order the following oxidizing agents by increasing strength under standard-state conditions:  $\text{Hg}^{2+}(aq)$ ,  $\text{Hg}^{2+}(aq)$ ,  $\text{Pb}^{2+}(aq)$ .

**19.135** What is the cell potential ( $E_{\text{cell}}$ ) of a spontaneous cell that is run at  $25^\circ\text{C}$  and contains  $[\text{Cr}^{3+}] = 0.10$  M and  $[\text{Ag}^+] = 1.0 \times 10^{-4}$  M?

**19.136** A strip of aluminum metal is placed into a beaker containing 1.0 M  $\text{CuSO}_4$ . **a** Will a spontaneous reaction occur? **b** If a spontaneous reaction does occur, write the half-reactions and describe what you would observe.

**19.137** Which of the following reactions occur spontaneously *as written*, with the production of a measurable electric current?

**19.138** How many grams of hydrogen can be produced by the electrolysis of water with a current of 0.433 A running for 5.00 min?

**19.139** The following two half-reactions are involved in a voltaic cell. At standard conditions, what species is produced at each electrode?

**19.140** Consider the following reaction run at standard conditions:

**a** Calculate the standard cell potential for this cell from standard free energies of formation (see Appendix C).

**b** Calculate the equilibrium constant for the reaction.

**c** How would the value of the equilibrium constant be affected if the concentration of  $\text{Fe}^{2+}(aq)$  were changed to 1.1 M?

**19.141** A beaker is found to contain  $\text{I}^-(aq)$ ,  $\text{Cu}^{2+}(aq)$ , and  $\text{Mg}^{2+}(aq)$  ions with  $\text{Ag}(s)$ .

**a** Would there be any spontaneous electrochemical reactions occurring in the mixture?

**b** A strip of aluminum metal is added to the beaker. What would you observe?

**c** Write the half-reactions for any of the ions that would spontaneously react with the  $\text{Al}(s)$  placed in the beaker.

**d** If you were to add a solution that contains  $\text{Al}^{3+}(aq)$  to the mixture, would you observe any reaction? Justify your answer.

**19.142** A 1.0-L sample of 1.0 M HCl solution has a 10.0 A current applied for 45 minutes. What is the pH of the solution after the electricity has been turned off?

**19.143** Consider the following cell running under standard conditions:

**a** Is this a voltaic cell?

**b** Which species is being reduced during the chemical reaction?

**c** Which species is the oxidizing agent?

**d** What happens to the concentration of  $\text{Fe}^{2+}(aq)$  as the reaction proceeds?

**e** How does the mass of  $\text{Al}(s)$  change as the reaction proceeds?

**19.144** A cell is constructed from some unknown elements designated as X and Y. Under standard conditions, a cell is created:  $\text{X}(s)|\text{X}^{3+}(aq)||\text{Y}^+(aq)|\text{Y}(s)$ . The maximum free-energy change for the reaction is  $-350$  kJ.

- a Is this an electrolytic cell? Justify your answer.  
 b If you were to decrease the concentration of  $Y^+(aq)$ , how would this affect the cell potential of the reaction?  
 c When the reaction reaches equilibrium, what is the value of  $\Delta G^\circ$ .  
 d What is the value of the equilibrium constant for the reaction?

**19.145** Two identical pieces of the same unknown metal are placed into 1.0 *M* solutions of  $\text{LiNO}_3(aq)$  and  $\text{Fe}(\text{NO}_3)_2(aq)$ . No reaction is observed in the  $\text{LiNO}_3(aq)$ ; however, the metal appears to dissolve in the  $\text{Fe}(\text{NO}_3)_2(aq)$ . If the possible metals are nickel and zinc, which metal would be expected to react? Calculate the cell potential under standard conditions for the metal that did react.

**19.146** A solution is prepared by dissolving 145 g of silver nitrate in enough water to make a total volume of 1.0 L.

A different solution is prepared by dissolving 105 grams of zinc nitrate in enough water to make a total volume of 1.1 L. A 375-mL portion of each solution is used to prepare an electrochemical cell using a salt bridge, a 20.0-g strip of zinc metal in the zinc nitrate solution, and a 15.0-g strip of silver metal in the silver nitrate solution.

- a Calculate the cell potential at 25°C.  
 b Calculate  $\Delta G^\circ$  for this cell.  
 c How would the cell potential change using an additional 25.0 mL of the silver nitrate solution?  
 d If the mass of the zinc metal strip were 40.0 grams, how would this affect the cell potential?  
 e If 0.5 g of sodium chloride were added to the silver nitrate solution in the half-cell, what affect would this have on the cell potential (increase or decrease)?

## Capstone Problems

**Key:** The problems under this heading combine skills, strategies, and concepts learned in previous chapters with those introduced in the current one.

**19.147** Consider the following cell reaction at 25°C.

Calculate the standard cell potential of this cell from the standard electrode potentials, and from this obtain  $\Delta G^\circ$  for the cell reaction. Use data in Appendix C to calculate  $\Delta H^\circ$ ; note that  $\text{Cr}(\text{H}_2\text{O})_6^{3+}(aq)$  equals  $\text{Cr}^{3+}(aq)$ . Use these values of  $\Delta H^\circ$  and  $\Delta G^\circ$  to obtain  $\Delta S^\circ$  for the cell reaction.

**19.148** Consider the following cell reaction at 25°C.

Calculate the standard cell potential of this cell from the standard electrode potentials, and from this obtain  $\Delta G^\circ$  for the cell reaction. Use data in Appendix C to calculate  $\Delta H^\circ$ ; note that  $\text{Cr}(\text{H}_2\text{O})_6^{3+}(aq)$  equals  $\text{Cr}^{3+}(aq)$ . Use these values of  $\Delta H^\circ$  and  $\Delta G^\circ$  to obtain  $\Delta S^\circ$  for the cell reaction.

**19.149** Under standard conditions for all concentrations, the following reaction is spontaneous at 25°C.

If  $[\text{H}^+]$  is decreased so that the pH = 3.60, what value will  $E_{\text{cell}}$  have, and will the reaction be spontaneous at this  $[\text{H}^+]$ ?

**19.150** Under standard conditions for all concentrations, the following reaction is spontaneous at 25°C.

If  $[\text{H}^+]$  is decreased so that the pH = 9.00, what value will  $E_{\text{cell}}$  have, and will the reaction be spontaneous at this  $[\text{H}^+]$ ?

**19.151** Under standard conditions for all concentrations, the following reaction is spontaneous at 25°C.

If  $[\text{H}^+]$  is adjusted by adding a buffer of 0.10 *M* NaOCN and 0.10 *M* HOCN ( $K_a = 3.5 \times 10^{-4}$ ), what value will  $E_{\text{cell}}$  have, and will the reaction be spontaneous at this  $[\text{H}^+]$ ?

**19.152** Under standard conditions for all concentrations, the following reaction is spontaneous at 25°C.

If  $[\text{H}^+]$  is adjusted by adding a buffer of 0.10 *M* NaClO and 0.10 *M* HClO ( $K_a = 3.5 \times 10^{-8}$ ), what value will  $E_{\text{cell}}$  have, and will the reaction be spontaneous at this  $[\text{H}^+]$ ?

**19.153** An electrode is prepared by dipping a silver strip into a solution saturated with silver thiocyanate, AgSCN, and containing 0.10 *M*  $\text{SCN}^-$ . The cell potential of the voltaic cell constructed by connecting this electrode as the cathode to the standard hydrogen half-cell as the anode is 0.45 V. What is the solubility product of silver thiocyanate?

**19.154** An electrode is prepared from liquid mercury in contact with a saturated solution of mercury(I) chloride,  $\text{Hg}_2\text{Cl}_2$ , containing 1.00 *M*  $\text{Cl}^-$ . The cell potential of the voltaic cell constructed by connecting this electrode as the cathode to the standard hydrogen half-cell as the anode is 0.268 V. What is the solubility product of mercury(I) chloride?

## 20

## Nuclear Chemistry

Technetium-99m,  $Tc-99m$ , is the most widely used radioisotope for medical diagnostics. Shown here is a scintigram (two-dimensional scan) of a patient's thyroid gland. It was produced by injecting the patient intravenously with a small amount of technetium-99m in the form of a solution of sodium pertechnetate,  $NaTcO_4$ . Gamma rays emitted by the technetium were detected to produce the scintigram.

### Energy of Nuclear Reactions

We investigate the source of the tremendous amount of energy released during nuclear reactions.

- 20.6** Mass–Energy Calculations
- 20.7** Nuclear Fission and Nuclear Fusion

**T**echnetium is an unusual element. Although a *d*-transition element (under manganese in Group 7B) with a small atomic number ( $Z = 43$ ), it has no stable isotopes. The nucleus of every technetium isotope is radioactive and decays, or disintegrates, to give an isotope of another element. Many of the technetium isotopes decay by emitting an electron from the nucleus.

Because of its nuclear instability, technetium is not found naturally on earth. Nevertheless, it is produced commercially in kilogram quantities from other elements by nuclear reactions, processes in which nuclei are transformed into different nuclei. Technetium (from the Greek *tekhnetos*, meaning “artificial”) was the first new element produced in the laboratory from another element. It was discovered in 1937 by Carlo Perrier and Emilio Segrè when the element molybdenum was bombarded with deuterons (nuclei of hydrogen, each having one proton and one neutron). Later, technetium was found to be a product of the fission, or splitting, of uranium nuclei. Technetium is produced in nuclear fission reactors used to generate electricity.

Technetium is one of the principal isotopes used in medical diagnostics based on radioactivity. A compound of technetium is injected into a vein, where it concentrates in certain body organs. The energy emitted by technetium nuclei is detected by special equipment and gives an image of these body organs. Figure 20.1 shows the image of a person’s skeleton obtained from technetium administered in this manner. The technetium is eliminated by the body after several hours.

In this chapter, we will look at nuclear processes such as those we have described for technetium. We will answer such questions as the following: How do you describe the radioactive decay of technetium? How do you describe the transformation of a molybdenum nucleus into technetium? How is technetium produced from uranium by nuclear fission, or splitting? What are some practical applications of nuclear processes?

## ▶ Radioactivity and Nuclear Bombardment Reactions

In chemical reactions, only the outer electrons of the atoms are disturbed. The nuclei of the atoms are not affected. In nuclear reactions, however, the nuclear changes that occur are independent of the chemical environment of the atom. For example, the nuclear changes in a radioactive  ${}^3_1\text{H}$  atom are the same if the atom is part of an  $\text{H}_2$  molecule or incorporated into  $\text{H}_2\text{O}$ .

We will look at two types of nuclear reactions. One type is **radioactive decay**, *the process in which a nucleus spontaneously disintegrates, giving off radiation*. The radiation consists of one or more of the following, depending on the nucleus: electrons, nuclear particles (such as neutrons), smaller nuclei (usually helium-4 nuclei), and electromagnetic radiation.

The second type of nuclear reaction is a **nuclear bombardment reaction**, *a nuclear reaction in which a nucleus is bombarded, or struck, by another nucleus or by a nuclear particle*. If there is sufficient energy in this collision, the nuclear particles of the reactants rearrange to give a product nucleus or nuclei. First, we will look at radioactive decay.

### 20.1 Radioactivity

The phenomenon of radioactivity was discovered by Antoine Henri Becquerel in 1896. He discovered that photographic plates develop bright spots when exposed to uranium minerals, and he concluded that the minerals give off some sort of radiation.

The radiation from uranium minerals was later shown to be separable by electric (and magnetic) fields into three types, alpha ( $\alpha$ ), beta ( $\beta$ ), and gamma ( $\gamma$ ) rays (Figure 20.2). *Alpha rays* bend away from a positive plate and toward a negative plate, indicating that they have a positive charge; they are now known to consist of helium-4 nuclei (nuclei with two protons and two neutrons). *Beta rays* bend in the opposite direction, indicating that they have a negative charge; they are now known to consist of high-speed electrons. *Gamma rays* are unaffected by electric

**Figure 20.1** ▲

**Image of a person’s skeleton obtained using an excited form of technetium-99m** A technetium compound was injected into the body, where it concentrated in bone tissue. Gamma rays (similar to X rays) emitted by technetium were detected by special equipment to produce this image.

**Figure 20.2** ▶

**Separation of the radiation from a radioactive material (uranium mineral)** The radiation separates into alpha ( $\alpha$ ), beta ( $\beta$ ), and gamma ( $\gamma$ ) rays when it passes through an electric field.

and magnetic fields: they have been shown to be a form of electromagnetic radiation that is similar to X rays, except they are higher in energy with shorter wavelengths (about 1 pm, or  $1 \times 10^{-12}$  m). Uranium minerals contain a number of radioactive elements, each emitting one or more of these radiations. Uranium-238, the main uranium isotope in uranium minerals, emits alpha rays and thereby decays, or disintegrates, to thorium-234 nuclei.

A sample of uranium-238 decays, or disintegrates, spontaneously over a period of billions of years. After about 30 billion years, the sample would be nearly gone. Strontium-90, formed by nuclear reactions that occur in nuclear weapons testing and nuclear power reactors, decays more rapidly. A sample of strontium-90 would be nearly gone after several hundred years. In either case, it is impossible to know when a particular nucleus will decay, although, as you will see in Section 20.4, precise information can be given about the rate of decay of any radioactive sample.

### Nuclear Equations

You can write an equation for the nuclear reaction corresponding to the decay of uranium-238 much as you would write an equation for a chemical reaction. You represent the uranium-238 nucleus by the *nuclide symbol*  ${}_{92}^{238}\text{U}$ . ◀ The radioactive decay of  ${}_{92}^{238}\text{U}$  by alpha-particle emission (loss of a  ${}_{2}^4\text{He}$  nucleus) is written

The product, in addition to being a helium-4 alpha particle, is thorium-234. This is an example of a **nuclear equation**, which is a *symbolic representation of a nuclear reaction*. Normally, only the nuclei are represented. It is not necessary to indicate the chemical compound or the electron charges for any ions involved, because the chemical environment has no effect on nuclear processes.

Reactant and product nuclei are represented in nuclear equations by their nuclide symbols. Other particles are given the following symbols, in which the subscript equals the charge and the superscript equals the total number of protons and neutrons in the particle (mass number):

Proton	${}_{1}^1\text{H}$	or	${}_{1}^1\text{P}$
Neutron	${}_{0}^1\text{n}$		
Electron	${}_{-1}^0\text{e}$	or	${}_{-1}^0\beta$
Positron	${}_{+1}^0\text{e}$	or	${}_{+1}^0\beta$
Gamma photon	${}_{0}^0\gamma$		

Nuclide symbols were introduced in Section 2.3. For uranium-238, you write

The decay of a nucleus with the emission of an electron,  ${}_{-1}^0\text{e}$ , is usually called beta emission, and the emitted electron is sometimes labeled  ${}_{-1}^0\beta$ . A **positron** is a particle similar to an electron, having the same mass but a positive charge. A **gamma photon** is a particle of electromagnetic radiation of short wavelength (about 1 pm, or  $10^{-12}$  m) and high energy.

### Example 20.1 Writing a Nuclear Equation

#### Gaining Mastery Toolbox

##### Critical Concept 20.1

There are six particles that can be involved in nuclear reactions: proton, neutron, beta (electron), positron, gamma photon, and alpha. When writing the particle symbol, the subscript equals the number of protons, and the superscript equals the sum of the protons and neutrons. In order to complete and balance nuclear reactions, you must know the name and symbol for each of these particles.

##### Solution Essentials:

- Nuclear particles: proton ( ${}^1_1\text{H}$ ), neutron ( ${}^1_0\text{n}$ ), beta ( ${}_{-1}^0\text{e}$ ), positron ( ${}^0_{+1}\text{e}$ ), gamma photon ( ${}^0_0\gamma$ ), and alpha ( ${}^4_2\text{He}$ )
- Nuclear equation
- Nuclide symbol

Write the nuclear equation for the radioactive decay of radium-226 by alpha decay to give radon-222. A radium-226 nucleus emits one alpha particle, leaving behind a radon-222 nucleus.

**Problem Strategy** Use the list of elements on the inside back cover to obtain the atomic numbers of radium and radon, so you can write their nuclide symbols for the nuclear equation. The nuclide symbol of the alpha particle is  ${}^4_2\text{He}$ .

**Solution** The nuclear equation is

**Answer Check** Make sure that you have written the nuclide symbols with the correct superscripts and subscripts.

**Exercise 20.1** Potassium-40 is a naturally occurring radioactive isotope. It decays to calcium-40 by beta emission. When a potassium-40 nucleus decays by beta emission, it emits one beta particle and gives a calcium-40 nucleus. Write the nuclear equation for this decay.

See Problems 20.33, 20.34, 20.35, and 20.36.

The total charge is conserved, or remains constant, during a nuclear reaction. This means that the sum of the subscripts (number of protons, or positive charges, in the nuclei) for the products must equal the sum of the subscripts for the reactants. For the equation in Example 20.1, the subscript for the reactant  ${}^{226}_{88}\text{Ra}$  is 88. For the products, the sum of the subscripts is  $86 + 2 = 88$ .

Similarly, the total number of *nucleons* (protons and neutrons) is conserved, or remains constant, during a nuclear reaction. This means that the sum of the superscripts (the mass numbers) for the reactants equals the sum of the superscripts for the products. For the equation in Example 20.1, the superscript for the reactant nucleus is 226. For the products, the sum of the superscripts is  $222 + 4 = 226$ .

Note that if all reactants and products but one are known in a nuclear equation, the identity of that one nucleus or particle can be easily obtained. This is illustrated in the next example.

### Example 20.2 Deducing a Product or Reactant in a Nuclear Equation

#### Gaining Mastery Toolbox

##### Critical Concept 20.2

The total charge (sum of all charges) and total number of nucleons (protons and neutrons) is conserved during a nuclear reaction. In a balanced nuclear reaction, the sum of all reactant superscripts must equal the sum of all product superscripts, and the sum of all reactant subscripts must equal the sum of all product subscripts.

Technetium-99 is a long-lived radioactive isotope of technetium. Each nucleus decays by emitting one beta particle. What is the product nucleus?

**Problem Strategy** First, write the nuclear equation using the symbol  ${}^A_Z\text{X}$  for the unknown nuclide or particle. Then, solve for  $A$  and  $Z$  using the following relations: (1) the sum of the subscripts for the reactants equals the sum of the subscripts for the products, and (2) the sum of the superscripts for the reactants equals the sum of the superscripts for the products.

**Solution** Technetium-99 has the nuclide symbol  ${}^{99}_{43}\text{Tc}$ . A beta particle is an electron; the symbol is  ${}_{-1}^0\text{e}$ . The nuclear equation is

(continued)

**Example 20.2** (continued)**Solution Essentials:**

- Nucleon
- Nuclear particles: proton ( ${}^1_1\text{H}$ ), neutron ( ${}^1_0\text{n}$ ), beta ( ${}^0_{-1}\text{e}$ ), positron ( ${}^0_{+1}\text{e}$ ), gamma photon ( ${}^0_0\gamma$ ), and alpha ( ${}^4_2\text{He}$ )
- Nuclear equation
- Nuclide symbol

From the superscripts, you can write

$$99 = A + 0, \text{ or } A = 99$$

Similarly, from the subscripts, you get

$$43 = Z - 1, \text{ or } Z = 43 + 1 = 44$$

Hence  $A = 99$  and  $Z = 44$ , so the product is  ${}^{99}_{44}\text{X}$ . Because element 44 is ruthenium, symbol Ru, you write the product nucleus as  ${}^{99}_{44}\text{Ru}$ .

**Answer Check** Although problems of this type are relatively simple, a very common error is not to account properly for the  $-1$  subscript of the beta particle.

**Exercise 20.2** Plutonium-239 decays by alpha emission, with each nucleus emitting one alpha particle. What is the other product of this decay?

See Problems  
20.37, 20.38,  
20.39, and 20.40.

**Nuclear Stability**

At first glance, the existence of several protons in the small space of a nucleus is puzzling. Why wouldn't the protons be strongly repelled by their like electric charges? The existence of stable nuclei with more than one proton is due to the nuclear force. The **nuclear force** is a strong force of attraction between nucleons that acts only at very short distances (about  $10^{-15}$  m). Beyond nuclear distances, these nuclear forces become negligible. Therefore, two protons that are much farther apart than  $10^{-15}$  m repel one another by their like electric charges. Inside the nucleus, however, two protons are close enough together for the nuclear force between them to be effective. This force in a nucleus can more than compensate for the repulsion of electric charges and thereby give a stable nucleus.

The protons and neutrons in a nucleus appear to have energy levels much as the electrons in an atom have energy levels. The **shell model of the nucleus** is a nuclear model in which protons and neutrons exist in levels, or shells, analogous to the shell structure that exists for electrons in an atom. Recall that in an atom, filled shells of electrons are associated with the special stability of the noble gases. The total numbers of electrons for these stable atoms are 2 (for He), 10 (for Ne), 18 (for Ar), and so forth. Experimentally, note that nuclei with certain numbers of protons or neutrons appear to be very stable. These numbers, called *magic numbers* and associated with specially stable nuclei, were later explained by the shell model. According to this theory, a **magic number** is the number of nuclear particles in a completed shell of protons or neutrons. Because nuclear forces differ from electrical forces, these numbers are not the same as those for electrons in atoms. For protons, the magic numbers are 2, 8, 20, 28, 50, and 82. Neutrons have these same magic numbers, as well as the magic number 126. For protons, calculations show that 114 should also be a magic number.

Some of the evidence for these magic numbers, and therefore for the shell model of the nucleus, is as follows. Many radioactive nuclei decay by emitting alpha particles, or  ${}^4_2\text{He}$  nuclei. There appears to be special stability in the  ${}^4_2\text{He}$  nucleus. It contains two protons and two neutrons; that is, it contains a magic number of protons (2) and a magic number of neutrons (also 2).

Another piece of evidence is seen in the final products obtained in natural radioactive decay. For example, uranium-238 decays to thorium-234, which in turn decays to protactinium-234, and so forth. Each product is radioactive and decays to another nucleus until the final product,  ${}^{206}_{82}\text{Pb}$ , is reached. This nucleus is stable. Note that it contains 82 protons, a magic number. Other radioactive decay series end at  ${}^{207}_{82}\text{Pb}$  and  ${}^{208}_{82}\text{Pb}$ , each of which has a magic number of protons. Note that  ${}^{208}_{82}\text{Pb}$  also has a magic number of neutrons ( $208 - 82 = 126$ ).

	Number of Stable Isotopes			
	157	52	50	5
Number of protons	Even	Even	Odd	Odd
Number of neutrons	Even	Odd	Even	Odd

Evidence also points to the special stability of pairs of protons and pairs of neutrons, analogous to the stability of pairs of electrons in molecules. Table 20.1 lists the number of stable isotopes that have an even number of protons and an even number of neutrons (157). By comparison, only 5 stable isotopes have an odd number of protons and an odd number of neutrons.

When you plot each stable nuclide on a graph with the number of protons ( $Z$ ) on the horizontal axis and the number of neutrons ( $N$ ) on the vertical axis, these stable nuclides fall in a certain region, or band, of the graph. The **band of stability** is the region in which stable nuclides lie in a plot of number of protons against number of neutrons. Figure 20.3 shows the band of stability; the rest of the figure is explained later in this section. For nuclides up to  $Z = 20$ , the ratio of neutrons to protons is about 1.0 to 1.1. As  $Z$  increases, however, the neutron-to-proton ratio increases to about 1.5. This increase in neutron-to-proton ratio with increasing  $Z$  is believed to result from the increasing repulsions of protons from their electric charges. More neutrons are required to give attractive nuclear forces to offset these repulsions.

It appears that when the number of protons becomes very large, the proton–proton repulsions become so great that stable nuclides are impossible. No stable nuclides are known with atomic numbers greater than 83. On the other hand, all elements with  $Z$  equal to 83 or less have one or more stable nuclides, with the exception of technetium ( $Z = 43$ ), as noted in the chapter opening, and promethium ( $Z = 61$ ).

Figure 20.3 ◀

**Band of stability** The stable nuclides, indicated by black dots, cluster in a band. Nuclides to the left of the band of stability usually decay by beta emission, whereas those to the right usually decay by positron emission or electron capture. Nuclides of  $Z > 83$  often decay by alpha emission.

**Example 20.3** Predicting the Relative Stabilities of Nuclides**Gaining Mastery Toolbox****Critical Concept 20.3**

There are several factors that contribute to nuclear stability: a full nuclear shell (magic number), an even number of protons and neutrons, and a proton-to-neutron ratio that lies close to the band of stability. When an element has an atomic number greater than 83, it will not be stable.

**Solution Essentials:**

- Band of stability
- Proton to neutron ratio
- Number of protons and neutrons in nuclide
- Magic number and the shell model of the nucleus
- Radioactive decay

One of the nuclides in each of the following pairs is radioactive; the other is stable. Which is radioactive and which is stable? Explain.

- a.  ${}^{208}_{84}\text{Po}$ ,  ${}^{209}_{83}\text{Bi}$     b.  ${}^{39}_{19}\text{K}$ ,  ${}^{40}_{19}\text{K}$     c.  ${}^{71}_{31}\text{Ga}$ ,  ${}^{76}_{31}\text{Ga}$

**Problem Strategy** You must decide which nuclide of each pair is more likely to be stable, based on the general principles stated in the preceding text.

**Solution** a. Polonium has an atomic number greater than 83, so  ${}^{208}_{84}\text{Po}$  is radioactive. Bismuth-209 has 126 neutrons (a magic number), so  ${}^{209}_{83}\text{Bi}$  is expected to be stable.

b. Of these two isotopes,  ${}^{39}_{19}\text{K}$  has a magic number of neutrons (20), so  ${}^{39}_{19}\text{K}$  is expected to be stable. The isotope  ${}^{40}_{19}\text{K}$  has an odd number of protons (19) and an odd number of neutrons (21). Because stable odd–odd nuclei are rare, you might expect  ${}^{40}_{19}\text{K}$  to be radioactive.

c. Of the two isotopes,  ${}^{76}_{31}\text{Ga}$  lies farther from the center of the band of stability, so it is more likely to be radioactive. For this reason, you expect  ${}^{76}_{31}\text{Ga}$  to be radioactive and  ${}^{71}_{31}\text{Ga}$ , which has an even number of neutrons and is close to the atomic mass of gallium, to be stable.

**Answer Check** When trying to determine whether a nuclide is radioactive, always first perform the simple check to see if the atomic number is greater than 83.

**Exercise 20.3** Of the following nuclides, two are radioactive. Which are radioactive and which is stable? Explain. a.  ${}^{118}_{50}\text{Sn}$ ; b.  ${}^{76}_{33}\text{As}$ ; c.  ${}^{227}_{89}\text{Ac}$ . See Problems 20.41 and 20.42.

**Types of Radioactive Decay**

There are six common types of radioactive decay; the first five are listed in Table 20.2. Note how the last column in Table 20.2 indicates the conditions where one would expect to observe a particular type of emission.

1. **Alpha emission** (abbreviated  $\alpha$ ): emission of a  ${}^4_2\text{He}$  nucleus, or alpha particle, from an unstable nucleus. An example is the radioactive decay of radium-226.

A CHEMIST Looks at . . .

## Magic Numbers

Maria Goeppert-Mayer (Figure 20.4) (1906–1972) received the 1963 Nobel Prize in Physics for her discovery of the shell structure of the nucleus (independently discovered by the German physicist J. Hans D. Jensen). Notably, she was the second woman to receive the Nobel Prize (Marie Curie was the first). In 1948, Goeppert-Mayer had noticed that the most abundant nuclei were those with special numbers of protons and neutrons. (These special numbers came to be called *magic numbers*.) Although these numbers had been noted earlier, her work was especially detailed and convincing, and it strongly pointed to a shell structure of the nucleus.

According to the shell model of the nucleus, protons and neutrons occupy independent sets of orbitals, similar to those of electrons in atoms. Nucleon orbitals have similar

quantum numbers too:  $n$  (principal quantum number) and  $l$  (orbital angular momentum quantum number). Each nucleon also has a spin of  $1/2$ . Unlike electrons, though, the  $l$  quantum number of a nucleon is not restricted by  $n$ . It can have any positive integer value, whatever the value of  $n$ , beginning with  $l = 0$ . For example, the orbitals corresponding to  $n = 1$  are  $1s$ ,  $1p$ ,  $1d$ ,  $1f$ , . . . (where  $s$  stands for  $l = 0$ ,  $p$  for  $l = 1$ , and so forth).

A simple scheme based on nucleons oscillating within the nucleus gives energy levels proportional to  $2(n - 1) + l$ , which leads to the following increasing order of energy levels:

$1s$ ,  $1p$ ,  $1d$  and  $2s$  (with about the same energies),  $1f$ , . . .

Similar to electrons, an  $s$  orbital holds 2 nucleons, a  $p$  orbital holds 6 nucleons, a  $d$  orbital holds 10 nucleons, and an  $f$  orbital holds 14 nucleons. Thus it takes 2 nucleons to fill a  $1s$  level, 8 nucleons to fill the  $1s$  and  $1p$  levels, 20 nucleons to fill the  $1s$ ,  $1p$ ,  $1d$ , and  $2s$  levels, and 34 nucleons to fill the  $1s$ ,  $1p$ ,  $1d$ ,  $2s$  and  $1f$  levels. The numbers 2, 8, and 20 are the first three magic numbers. After that, however, this simple scheme fails.

Goeppert-Mayer was able to solve this problem by noting that in nuclei, the orbital angular momentum of each nucleon couples to its spin (equal to  $1/2$ ) to give a total angular momentum of either  $l + 1/2$  or  $l - 1/2$ . Each level of given  $l$  thus splits by this *spin-orbit coupling* into two sublevels, with the sublevel of angular momentum  $l + 1/2$  being lower in energy. For example, a  $1f$  level is split to give a lower level that Goeppert-Mayer showed can hold 8 nucleons and an upper level that can hold 6 nucleons for a total of 14 for an  $f$  shell. Therefore, the magic number after 20 is  $20 + 8 = 28$  (not  $20 + 14 = 34$ ). She was able to show that the shell model reproduced the other magic numbers, as well.

Figure 20.4 ▲

Maria Goeppert-Mayer

■ See Problems 20.103 and 20.104.

The product nucleus has an atomic number that is two less, and a mass number that is four less, than that of the original nucleus.

- Beta emission** (abbreviated  $\beta$  or  $\beta^-$ ): *emission of a high-speed electron from an unstable nucleus*. Beta emission is the result of the conversion of a neutron to a proton.

An example of beta emission is the radioactive decay of carbon-14.

The product nucleus has an atomic number that is one more than that of the original nucleus. The mass number remains the same.

3. **Positron emission** (abbreviated  $\beta^+$ ): *emission of a positron from an unstable nucleus.* A positron, denoted in nuclear equations as  ${}^0_1\text{e}$ , is a particle identical to an electron in mass but having a positive instead of a negative charge. Positron emission is the result of the conversion of a proton to a neutron. ◀

The radioactive decay of technetium-95 is an example of positron emission.

The product nucleus has an atomic number that is one less than that of the original nucleus. The mass number remains the same.

4. **Electron capture** (abbreviated EC): *the decay of an unstable nucleus by capturing, or picking up, an electron from an inner orbital of an atom.* In effect, a proton is changed to a neutron, as in positron emission.

An example is given by potassium-40, which has a natural abundance of 0.012%. ◀ Potassium-40 can decay by electron capture, as well as by beta and positron emissions. The equation for electron capture is

The product nucleus has an atomic number that is one less than that of the original nucleus. The mass number remains the same. When another orbital electron fills the vacancy in the inner-shell orbital created by electron capture, an X-ray photon is emitted.

5. **Gamma emission** (abbreviated  $\gamma$ ): *emission from an excited nucleus of a gamma photon, corresponding to radiation with a wavelength of about  $10^{-12}$  m.* ◀ In many cases, radioactive decay results in a product nucleus that is in an excited state. As in the case of atoms, the excited state is unstable and goes to a lower-energy state with the emission of electromagnetic radiation. For nuclei, this radiation is in the gamma-ray region of the spectrum.

Positrons are annihilated as soon as they encounter electrons. When a positron and an electron collide, both particles vanish with the emission of two gamma photons that carry away the energy.

Most of the argon in the atmosphere is believed to have resulted from the radioactive decay of  ${}^{40}_{19}\text{K}$ .

Recall from Chapter 7 that the energy of a photon can be calculated by the equation  $E = hc/\lambda$ , where  $h$  is Planck's constant,  $c$  is the speed of light, and  $\lambda$  is the wavelength of the radiation.

Often gamma emission occurs very quickly after radioactive decay. In some cases, however, an excited state has significant lifetime before it emits a gamma photon. A **metastable nucleus** is a nucleus in an excited state with a lifetime of at least one nanosecond ( $10^{-9}$  s). In time, the metastable nucleus decays by gamma emission. An example is metastable technetium-99, denoted  ${}_{43}^{99m}\text{Tc}$ , which is used in medical diagnosis, as discussed in Section 20.5.

The product nucleus is simply a lower-energy state of the original nucleus, so there is no change of atomic number or mass number.

6. **Spontaneous fission:** the spontaneous decay of an unstable nucleus in which a heavy nucleus of mass number greater than 89 splits into lighter nuclei and energy is released. For example, a uranium-236 atom can spontaneously undergo the following nuclear reaction:

This process will be discussed further in Section 20.6.

Nuclides outside the band of stability (Figure 20.3) are generally radioactive. Nuclides to the left of the band of stability have a neutron-to-proton ratio ( $N/Z$ ) larger than that needed for stability. These nuclides tend to decay by beta emission. Beta emission reduces the neutron-to-proton ratio, because in this process a neutron is changed to a proton. The product is a stabler nuclide. In contrast, nuclides to the right of the band of stability have a neutron-to-proton ratio smaller than that needed for stability. These nuclides tend to decay by either positron emission or electron capture. Both processes convert a proton to a neutron, increasing the neutron-to-proton ratio and giving a stabler product nuclide. The types of radioactive decay expected of unstable nuclides are noted in Figure 20.3.

Consider a series of isotopes of a given element, such as carbon. Carbon-12 and carbon-13 are stable isotopes, whereas the other isotopes of carbon are radioactive. The isotopes of mass number smaller than 12 decay by positron emission. For example, carbon-11 decays by positron emission to boron-11.

Carbon-11 has a neutron-to-proton ratio of  $5/6$  ( $= 0.8$ ), which increases in the product boron-11 to  $6/5$  ( $1.2$ ). The isotopes of carbon with mass number greater than 13 decay by beta emission. Carbon-14 decays by beta emission to produce nitrogen-14.

Carbon-14 has a neutron-to-proton ratio of  $8/6$  ( $1.3$ ), which decreases in the product nitrogen-14 to  $7/7$  ( $1.0$ ).

Now consider the radioactive isotope phosphorus-30. You can predict the expected type of radioactive decay of this isotope by noting whether the mass number is less than or greater than the mass number of stable isotopes. Generally, the mass numbers of stable isotopes will be close to the numerical value of the atomic mass of the element. The atomic mass of phosphorus is 31.0 amu, so you might expect phosphorus-31 to be a stable isotope (which it is). Phosphorus-30 has a mass number less than that of the stable isotope phosphorus-31. Therefore, you expect that phosphorus-30 will decay by either positron emission or electron capture. Positron emission is actually observed.

Positron emission and electron capture are competing radioactive decay processes, and what is observed depends on the relative rates of the two processes. The rate of electron capture increases with atomic number of the decaying nuclide and therefore becomes important in heavier elements. Positron emission is generally seen in lighter elements (recall that phosphorus-30 decays by positron emission). However, in the very heavy elements, especially those with  $Z$  greater than 83, radioactive decay is often by alpha emission (noted in Figure 20.3 at the top of the figure).  ${}^{238}_{92}\text{U}$ ,  ${}^{226}_{88}\text{Ra}$ , and  ${}^{232}_{90}\text{Th}$  are examples of alpha emitters.

### Example 20.4 Predicting the Type of Radioactive Decay

#### Gaining Mastery Toolbox

##### Critical Concept 20.4

The total number of protons or the proton-to-neutron ratio ( $N/Z$ ) can be used to predict the type of nuclear decay of a nuclide. The last column of Table 20.2 provides guidance for linking the type of nuclear decay to these quantities.

##### Solution Essentials:

- Alpha emission, beta emission, positron emission, electron capture, and gamma emission
- Nuclear conditions that cause a particular type of decay (Table 20.2)
- Nuclear particles: proton ( ${}^1_1\text{H}$ ), neutron ( ${}^1_0\text{n}$ ), beta ( ${}^0_{-1}\text{e}$ ), positron ( ${}^0_{+1}\text{e}$ ), gamma photon ( ${}^0_0\gamma$ ), and alpha ( ${}^4_2\text{He}$ )
- Nuclear equation
- Nuclide symbol

Predict the expected type of radioactive decay for each of the following radioactive nuclides: a.  ${}^{47}_{20}\text{Ca}$ ; b.  ${}^{25}_{13}\text{Al}$ .

**Problem Strategy** Compare each nuclide with the stable nuclides of the same element. A nuclide with an  $N/Z$  ratio greater than that of the stable nuclides is expected to exhibit beta emission. A nuclide with an  $N/Z$  ratio less than that of the stable nuclides is expected to exhibit positron emission or electron capture; electron capture is important with heavier elements. Since you are comparing nuclides of the same  $Z$ , you can compare mass numbers ( $= N + Z$ ), rather than  $N/Z$ .

##### Solution

- The atomic mass of calcium is 40.1 amu, so you expect calcium-40 to be a stable isotope. Calcium-47 has a mass number greater than that of the stable isotope, so you expect it to decay by **beta emission**. (This is the observed behavior of calcium-47.)
- The atomic mass of aluminum is 27.0 amu, so you expect aluminum-27 to be a stable isotope. The mass number of aluminum-25 is less than 27, so you expect aluminum-25 to decay by either **positron emission or electron capture**. Positron emission is actually observed.

**Answer Check** To answer these types of questions correctly, you must understand how the  $N/Z$  ratio of nuclides determines the type of emission from radioactive nuclides.

**Exercise 20.4** Predict the type of decay expected for each of the following radioactive nuclides: a.  ${}^{13}_7\text{N}$ ; b.  ${}^{26}_{11}\text{Na}$ .

See Problems 20.43 and 20.44.

### Radioactive Decay Series

All nuclides with atomic number greater than  $Z = 83$  are radioactive, as we have noted. Many of these nuclides decay by alpha emission. Alpha particles, or  ${}^4_2\text{He}$  nuclei, are especially stable and are formed in the radioactive nucleus at the moment of decay. By emitting an alpha particle, the nucleus reduces its atomic number, becoming more stable. However, if the nucleus has a very large atomic number, the product nucleus is also radioactive. Natural radioactive elements, such as uranium-238, give a **radioactive decay series**, a sequence in which one radioactive nucleus decays to a second, which then decays to a third, and so forth. Eventually, a stable nucleus, which is an isotope of lead, is reached.

Figure 20.5 ◀

**Uranium-238 radioactive decay series** Each nuclide occupies a position on the graph determined by its atomic number and mass number. Alpha decay is shown by a red diagonal line. Beta decay is shown by a short blue horizontal line.

Three radioactive decay series are found naturally. One of these series begins with uranium-238. Figure 20.5 shows the sequence of nuclear decay processes. In the first step, uranium-238 decays by alpha emission to thorium-234.

This step is represented in Figure 20.5 by a red arrow labeled  $\alpha$ . Each alpha decay reduces the atomic number by 2 and the mass number by 4. The atomic number and mass number of each nuclide are given by its horizontal and vertical position on the graph. Thorium-234 in turn decays by beta emission to protactinium-234, which decays by beta emission to uranium-234.

Beta emission is represented in Figure 20.5 by a blue arrow labeled  $\beta$ . Each beta decay increases the atomic number by one but has no effect on the mass number. After the decay of protactinium-234 and the formation of uranium-234, there are a number of alpha-decay steps. The final product of the series is lead-206.

Natural uranium is 99.28%  ${}_{92}^{238}\text{U}$ , which decays as we have described. However, the natural element also contains 0.72%  ${}_{92}^{235}\text{U}$ . This isotope starts a second radioactive decay series, which consists of a sequence of alpha and beta decays, ending with lead-207. The third naturally occurring radioactive decay series begins with thorium-232 and ends with lead-208. All three radioactive decay series found naturally end with an isotope of lead.

### CONCEPT CHECK 20.1

You have two samples of water, each made up of different isotopes of hydrogen: one contains  ${}^1_1\text{H}_2\text{O}$  and the other,  ${}^3_1\text{H}_2\text{O}$ .

- Would you expect these two water samples to be chemically similar?
- Would you expect these two water samples to be physically the same?
- Which one of these water samples would you expect to be radioactive?

## 20.2 Nuclear Bombardment Reactions

The nuclear reactions discussed in the previous section are radioactive decay reactions, in which a nucleus spontaneously decays to another nucleus and emits a particle, such as an alpha or beta particle. In 1919, Ernest Rutherford discovered that it is possible to change the nucleus of one element into the nucleus of another element by processes that can be controlled in the laboratory. **Transmutation** is the change of one element to another by bombarding the nucleus of the element with nuclear particles or nuclei.

### Transmutation

Rutherford used a radioactive element as a source of alpha particles and allowed these particles to collide with nitrogen nuclei. He discovered that protons are ejected in the process. The equation for the nuclear reaction is

The experiments were repeated on other light nuclei, most of which were transmuted to other elements with the ejection of a proton. These experiments yielded two significant results. First, they strengthened the view that all nuclei contain protons. Second, they showed for the first time that it is possible to change one element into another under laboratory control.

When beryllium is bombarded with alpha particles, a penetrating radiation is given off that is not deflected by electric or magnetic fields. Therefore, the radiation does not consist of charged particles. The British physicist James Chadwick (1891–1974) suggested in 1932 that the radiation from beryllium consists of neutral particles, each with a mass approximately that of a proton. The particles are called neutrons. The reaction that resulted in the discovery of the neutron is

In 1933, a nuclear bombardment reaction was used to produce the first artificial radioactive isotope. Irène and Frédéric Joliot-Curie found that aluminum bombarded with alpha particles produces phosphorus-30, which decays by emitting positrons. The reactions are

Phosphorus-30 was the first radioactive nucleus produced in the laboratory. Since then over a thousand radioactive isotopes have been made. ◀

Nuclear bombardment reactions are often referred to by an abbreviated notation. For example, the reaction

is abbreviated  ${}^1_7\text{N}(\alpha, \text{p}){}^1_8\text{O}$ . In this notation, you first write the nuclide symbol for the original nucleus (target). Then, in parentheses, you write the symbol for the projectile particle (incoming particle), followed by a comma and the symbol for the ejected particle. After the last parenthesis, you write the nuclide symbol for the product nucleus. The following symbols are used for particles:

Neutron	n
Proton	p
Deuteron, ${}^2_1\text{H}$	d
Alpha, ${}^4_2\text{He}$	$\alpha$

Some of the uses of radioactive isotopes are discussed in Section 20.5.

**Example 20.5 Using the Notation for a Bombardment Reaction****Gaining Mastery Toolbox****Critical Concept 20.5**

The abbreviated notation for nuclear bombardment reactions requires that symbols be used to denote the nuclear particles. The symbols are: n for neutron, p for proton, d for deuteron ( ${}^2_1\text{H}$ ), and  $\alpha$  for alpha ( ${}^4_2\text{He}$ ).

**Solution Essentials:**

- Particle symbols for nuclear bombardment reactions
- Abbreviated nuclear bombardment notation
- Nuclear equation

- a. Write the abbreviated notation for the following bombardment reaction, in which neutrons were first discovered.

- b. Write the nuclear equation for the bombardment reaction denoted  ${}^{27}_{13}\text{Al}(p, d){}^{26}_{13}\text{Al}$ .

**Problem Strategy** Understand and use the abbreviated notation and particle symbols for nuclear reactions.

**Solution** a. The notation is  ${}^9_4\text{Be}(\alpha, n){}^{12}_6\text{C}$ .

b. The nuclear equation is

**Answer Check** You can check your answers by working backward to see whether they lead to the representations given in the problem.

**Exercise 20.5** a. Write the abbreviated notation for the reaction

b. Write the nuclear equation for the bombardment reaction  ${}^{12}_6\text{C}(d, p){}^{13}_6\text{C}$ .

See Problems 20.47, 20.48, 20.49, and 20.50.

Elements of large atomic number merely scatter, or deflect, alpha particles from natural sources, rather than giving a transmutation reaction. These elements have nuclei of large positive charge, and the alpha particle must be traveling very fast in order to penetrate the nucleus and react. Alpha particles from natural sources do not have sufficient kinetic energy. To shoot charged particles into heavy nuclei, it is necessary to accelerate the charged particles.

A **particle accelerator** is a device used to accelerate electrons, protons, alpha particles, and other ions to very high speeds. The basis of a particle accelerator is the fact that a charged particle will accelerate toward a plate having a charge opposite in sign to that of the particle. It is customary to measure the kinetic energies of these particles in units of electron volts. An **electron volt (eV)** is the quantity of energy that would have to be imparted to an electron (whose charge is  $1.602 \times 10^{-19} \text{ C}$ ) to accelerate it by one volt potential difference.

$$1 \text{ eV} = (1.602 \times 10^{-19} \text{ C}) \times (1 \text{ V}) = 1.602 \times 10^{-19} \text{ J}$$

Typically, particle accelerators give charged particles energies of millions of electron volts (MeV). To keep the accelerated particles from colliding with molecules of gas, the apparatus is enclosed and evacuated to low pressures, about  $10^{-6} \text{ mmHg}$  or less.

A charged particle can be accelerated in stages to very high kinetic energy. Figure 20.6 shows a diagram of a **cyclotron**, a type of particle accelerator consisting of two hollow, semicircular metal electrodes called *dees* (because the shape resembles the letter *D*), in which charged particles are accelerated by stages to higher and higher kinetic energies. Ions introduced at the center of the cyclotron are accelerated in the space between the two dees. Magnet poles (not shown in the figure) above and below the dees keep the ions moving in an enlarging spiral path. The dees are connected to a high-frequency electric current that changes their polarity so that each time an ion moves into the space between the dees, it is accelerated. Thus, the ion is continually accelerated until it finally leaves the cyclotron at high speed. Outside the cyclotron, the ions are directed toward a target element so that investigators may study nuclear reactions or prepare isotopes.

Technetium was first prepared by directing **deuterons**, or nuclei of hydrogen-2 atoms, from a cyclotron to a molybdenum target. ▶ The nuclear reaction is  ${}^{96}_{42}\text{Mo}(d, n){}^{97}_{43}\text{Tc}$ , or

The hydrogen-2 atom is often called deuterium and given the symbol D. It is a stable isotope with a natural abundance of 0.015%. Deuterium was discovered in 1931 by Harold Urey and coworkers and was first prepared in pure form by G. N. Lewis.

Figure 20.6 ▶

**A cyclotron** Positive ions are introduced at the center of the cyclotron. A fraction of the ions will be crossing the gap between the dees when the electric polarities are just right to accelerate them. (The positive ions are accelerated toward the negative dee and away from the positive dee.) The dees alternate in polarities, so that these ions continue to be accelerated each time they pass between the gap in the dees. Magnet poles above and below the dees produce a magnetic field that keeps the ions moving in a spiral path within the dees. At the end of their path, the ions encounter a negative electrode that deflects them to a target material.

Fermilab Visual Media Services

Figure 20.7 ▲

**The Fermilab accelerator in Batavia, Illinois** The tunnel of the main accelerator is shown here. Protons are accelerated in the upper ring of conventional magnets (red and blue) to 400 billion electron volts. These protons are then injected into the lower ring of superconducting magnets (yellow), where they are accelerated to almost a trillion electron volts.

The energies of particles obtained from a cyclotron are limited (to about 20 MeV for deuterons, for example). For higher energies, more sophisticated accelerators are required, such as the Fermilab in Batavia Illinois (Figure 20.7) and CERN's Large Hadron Collider in Switzerland.

### Transuranium Elements

The **transuranium elements** are *elements with atomic numbers greater than that of uranium ( $Z = 92$ ), the naturally occurring element of greatest  $Z$* . In 1940, E. M. McMillan and P. H. Abelson, at the University of California at Berkeley, discovered the first transuranium element. They produced an isotope of element 93, which they named neptunium, by bombarding uranium-238 with neutrons. This gave uranium-239, by the capture of a neutron, and this nucleus decayed in a few days by beta emission to neptunium-239.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

The next transuranium element to be discovered was plutonium ( $Z = 94$ ). Deuterons, the positively charged nuclei of hydrogen-2, were accelerated by a cyclotron and directed at a uranium target to give neptunium-238, which decayed to plutonium-238.

Another isotope of plutonium, plutonium-239, is now produced in large quantity in nuclear reactors, as described in Section 20.7. Plutonium-239 is used for nuclear weapons.

The discovery of the next two transuranium elements, americium ( $Z = 95$ ) and curium ( $Z = 96$ ), depended on an understanding of the correct positions in the

periodic table of the elements beyond actinium ( $Z = 89$ ). It had been thought that these elements should be placed after actinium under the  $d$ -transition elements, so uranium was placed in Group 6B under tungsten. However, Glenn T. Seaborg, then at the University of California, Berkeley, postulated a second series of elements to be placed at the bottom of the periodic table, under the lanthanides, as shown in modern tables (see inside front cover). These elements, the actinides, would be expected to have chemical properties similar to those of the lanthanides. Once they understood this, Seaborg and others were able to use the predicted chemical behaviors of the actinides to separate americium and curium.

Figure 20.8 shows the apparatus used by Albert Ghiorso at the Lawrence Berkeley Laboratory in Berkeley, California, for the discovery of elements 104, 105, and 106. A team of scientists led by Peter Armbruster in Darmstadt, Germany, created elements 107 to 109 in the early 1980s by bombarding other elements with heavy-metal ions. During the 1994–1996 period, they reported the discovery of elements 110, 111, and 112. Recent work has yielded other elements, including the heaviest to date, 118. ►

The transuranium elements have a number of commercial uses. Plutonium-238 emits only alpha radiation, which is easily stopped by shielding. The isotope has been used as a power source for space satellites, navigation buoys, and heart pacemakers. Americium-241 is both an alpha-ray and a gamma-ray emitter. The gamma rays are used in devices that measure the thickness of materials such as metal sheets. Americium-241 is also used in home smoke detectors, in which the alpha radiation ionizes the air in a chamber within the detector and renders it electrically conducting. Smoke reduces the conductivity of the air, and this reduced conductivity is detected by an alarm circuit.

Figure 20.9 shows the High Flux Isotope Reactor at Oak Ridge National Laboratory, where technicians produce transuranium elements by bombarding plutonium-239 with neutrons. Neutrons are produced by nuclear fission, a process discussed in Section 20.7.

Lawrence Berkeley Laboratory

**Figure 20.8** ▲

**The vertical wheel, an apparatus used in the discovery of elements 104, 105, and 106** The apparatus was designed by Albert Ghiorso and colleagues. They synthesized element 106 by bombarding californium-249 with oxygen-18. The products were whisked by gas jets to the vertical wheel, where they were deposited (at the top). Detectors around the periphery of the wheel monitored the alpha activity to identify the products. Binary-coded holes label the positions around the wheel for computer collection of data.

For further discussion on this topic, see the essay in Section 2.5.

### Example 20.6 Determining the Product Nucleus in a Nuclear Bombardment Reaction

#### Gaining Mastery Toolbox

##### Critical Concept 20.6

The total charge (sum of all charges) and total number of nucleons (protons and neutrons) is conserved during a nuclear reaction. In a balanced nuclear reaction, the sum of all reactant superscripts must equal the sum of all product superscripts, and the sum of all reactant subscripts must equal the sum of all product subscripts. Coefficients are used to indicate the number of nuclides.

##### Solution Essentials:

- Nucleon
- Nuclear particles: proton ( ${}^1_1\text{H}$ ), neutron ( ${}^1_0\text{n}$ ), beta ( ${}^0_{-1}\text{e}$ ), positron ( ${}^0_{+1}\text{e}$ ), gamma photon ( $\gamma$ ), and alpha ( ${}^4_2\text{He}$ )
- Nuclear equation
- Nuclide symbol

Plutonium-239 was bombarded by alpha particles. Each  ${}^{239}_{94}\text{Pu}$  nucleus was struck by one alpha particle and emitted one neutron. What was the product nucleus?

**Problem Strategy** Apply a strategy similar to that used to solve Example 20.2.

**Solution** You can write the nuclear equation as follows:

To balance this equation, write

$$\begin{aligned} 239 + 4 &= A + 1 && \text{(from superscripts)} \\ 94 + 2 &= Z + 0 && \text{(from subscripts)} \end{aligned}$$

Hence,

$$\begin{aligned} A &= 239 + 4 - 1 = 242 \\ Z &= 94 + 2 = 96 \end{aligned}$$

The product is  ${}^{242}_{96}\text{Cm}$ .

**Answer Check** Be careful in problems like this where the nuclides have coefficients; in those cases, make sure that you count correctly.

**Exercise 20.6** Carbon-14 is produced in the upper atmosphere when a particular nucleus is bombarded with neutrons. A proton is ejected for each nucleus that reacts. What is the identity of the nucleus that produces carbon-14 by this reaction?

See Problems 20.53, 20.54, 20.55, and 20.56.

Oak Ridge National Laboratory

Figure 20.9 ▲

### The High Flux Isotope Reactor at Oak Ridge National Laboratory

The reactor in which transuranium isotopes are produced lies beneath a protecting pool of water. Visible light is emitted by high-energy particles moving through the water.

Gamma and low-energy alpha particles are better detected by scintillation counters. These counters are filled with solids or liquids, which are more likely to stop gamma rays. Also, low-energy alpha particles may be absorbed by the window of the Geiger counter and go undetected.

Figure 20.10 ►

**A Geiger counter** A particle of radiation enters the thin window and passes into the gas. Energy from the particle ionizes gas molecules, giving positive ions and electrons, which are accelerated to the electrodes. The electrons, which move faster, strike the wire anode and create a pulse of current. Pulses from radiation particles are counted.

## 20.3 Radiations and Matter: Detection and Biological Effects

Radiations from nuclear processes affect matter in part by dissipating energy in it. An alpha, beta, or gamma particle traveling through matter dissipates energy by ionizing atoms or molecules, producing positive ions and electrons. In some cases, these radiations may also excite electrons in matter. When these electrons undergo transitions back to their ground states, light is emitted. The ions, free electrons, and light produced in matter can be used to detect nuclear radiations. Because nuclear radiations can ionize molecules and break chemical bonds, they adversely affect biological organisms. We will first look at the detection of nuclear radiations and then briefly discuss biological effects and radiation dosage in humans.

### Radiation Counters

Two types of devices—*ionization counters* and *scintillation counters*—are used to count particles emitted from radioactive nuclei and other nuclear processes. Ionization counters detect the production of ions in matter. Scintillation counters detect the production of scintillations, or flashes of light.

A **Geiger counter** (Figure 20.10), a kind of ionization counter used to count particles emitted by radioactive nuclei, consists of a metal tube filled with gas, such as argon. The tube is fitted with a thin glass or plastic window through which radiation enters. A wire runs down the tube's center, from which the wire is insulated. The tube and wire are connected to a high-voltage source so that the tube becomes the negative electrode and the wire the positive electrode. Normally the gas in the tube is an insulator and no current flows through it. However, when radiation, such as an alpha particle,  ${}^4_2\text{He}^{2+}$ , passes through the window of the tube and into the gas, atoms are ionized. Free electrons are quickly accelerated to the wire. As they are accelerated to the wire, additional atoms may be ionized from collisions with these electrons and more electrons set free. An avalanche of electrons is created, and this gives a pulse of current that is detected by electronic equipment. The amplified pulse activates a digital counter or gives an audible “click.”

Alpha and beta particles can be detected directly by a Geiger counter. ◀ To detect neutrons, boron trifluoride is added to the gas in the tube. Neutrons react with boron-10 nuclei to produce alpha particles, which can then be detected.

A **scintillation counter** (Figure 20.11) is a device that detects nuclear radiation from flashes of light generated in a material by the radiation. A phosphor is a substance that emits flashes of light when struck by radiation. Rutherford used zinc sulfide as a phosphor to detect alpha particles. A sodium iodide crystal containing thallium(I) iodide is used as a phosphor for gamma radiation. (Excited technetium-99

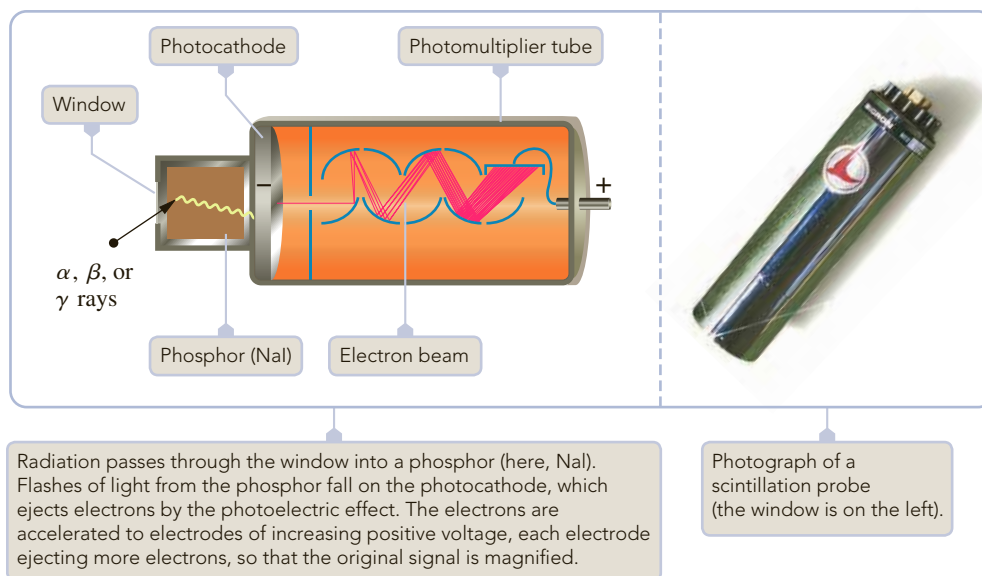

Figure 20.11 ◀

A scintillation counter probe

Courtesy of Bicon, division of Saint-Gobain Industrial Ceramics, Inc.

emits gamma rays and is used for medical diagnostics. The gamma rays are detected by a scintillation counter.)

The flashes of light from the phosphor are detected by a *photomultiplier*. A photon of light from the phosphor hits a photoelectric-sensitive surface (the photocathode). ▶ This emits an electron, which is accelerated by a positive voltage to another electrode, from which several electrons are emitted. These electrons are accelerated by a higher voltage to the next electrode, from which more electrons are emitted, and so forth. The result is that a single electron may produce a million electrons and therefore a detectable pulse of electric current.

A radiation counter can be used to measure the rate of nuclear disintegrations in a radioactive material. The **activity of a radioactive source** is *the number of nuclear disintegrations per unit time occurring in a radioactive material*. A **curie (Ci)** is a unit of activity equal to  $3.700 \times 10^{10}$  disintegrations per second. ▶ For example, a sample of technetium having an activity of  $1.0 \times 10^{-2}$  Ci is decaying at the rate of  $(1.0 \times 10^{-2}) \times (3.7 \times 10^{10}) = 3.7 \times 10^8$  nuclei per second.

The photoelectric effect was discussed in Section 7.2.

The curie was originally defined as the number of disintegrations per second from 1.0 g of radium-226.

### Biological Effects and Radiation Dosage

Although the quantity of energy dissipated in a biological organism from a radiation dosage might be small, the effects can be quite damaging because important chemical bonds may be broken. DNA in the chromosomes of the cell is especially affected, which interferes with cell division (Figure 20.12). Cells that divide the fastest, such as those in the blood-forming tissue in bone marrow, are most affected by nuclear radiations.

To monitor the effect of nuclear radiations on biological tissue, it is necessary to have a measure of radiation dosage. The **rad** (from radiation absorbed dose) is *the dosage of radiation that deposits  $1 \times 10^{-2}$  J of energy per kilogram of tissue*. However, the biological effect of radiation depends not only on the energy deposited

Figure 20.12 ◀

**Examples of damage to DNA from nuclear radiation** Damaged DNA can prevent cells from properly functioning and increase the likelihood of tumors.

in the tissue but also on the type of radiation. For example, neutrons are more destructive than gamma rays of the same radiation dosage measured in rads. A **rem** is a unit of radiation dosage used to relate various kinds of radiation in terms of biological destruction. It equals the rad times a factor for the type of radiation, called the relative biological effectiveness (RBE).

$$\text{rems} = \text{rads} \times \text{RBE}$$

Beta and gamma radiations have an RBE of about 1, whereas neutron radiation has an RBE of about 5 and alpha radiation an RBE of about 10. ◀

The effects of radiation on a person depend not only on the dosage but also on the length of time in which the dose was received. A series of small doses has less overall effect than these dosages given all at once. A single dose of about 500 rems is fatal to most people, and survival from a much smaller dose can be uncertain or leave the person chronically ill. Detectable effects are seen with doses as low as 30 rems. Continuous exposure to such low levels of radiation may result in cancer or leukemia. At even lower levels, whether the radiation dose is safe depends on the possible genetic effects of the radiation. Because radiation can cause chromosome damage, heritable defects are possible.

Safe limits for radiations are much debated. Although there may not be a strictly safe limit, it is important to have in mind the magnitude of the radiations humans may be subjected to. The background radiation we all receive results from cosmic rays (radiations from space) and natural radioactivity. This averages about 0.1 rem per year but varies considerably with location. Uranium and its decay products in the soil are an important source of background radiation. ◀ Another source is potassium-40, a radioactive isotope with a natural abundance of 0.012%. In addition to natural background radiation, we may receive radiation from other fairly common sources. The most important of these are X rays used in medical diagnosis. The average person receives a radiation dose from this source that is about equal to that of the natural background. Very small radiation sources include consumer items such as television sets and luminous watches.

The background radiation to which we are all subjected has increased slightly since the advent of nuclear technology. Fallout from atmospheric testing of nuclear weapons increased this background by several percent, but it has decreased since atmospheric testing was banned. The radiation contributed by nuclear power plants is only a fraction of a percent of the natural background.

Sources of alpha radiation outside the body are relatively harmless, because the radiation is absorbed by the skin. Internal sources, however, are very destructive.

Soils contain varying amounts of uranium-238, which decays in several steps to radium-226, then to radon-222, a gas (see Figure 20.5). Some homes situated in areas of high uranium content have been found to accumulate radon gas. Radon has a half-life of 3.8 days, decaying by alpha emission to radioactive lead, bismuth, and polonium. These decay products can remain in the lungs and may lead to lung cancer.

#### CONCEPT CHECK 20.2

If you are internally exposed to 10 rads of  $\alpha$ ,  $\beta$ , and  $\gamma$  radiation, which form of radiation will cause the greatest biological damage?

## 20.4 Rate of Radioactive Decay

Although technetium-99 is radioactive and decays by emitting beta particles (electrons), it is impossible to say when a particular nucleus will disintegrate. A sample of technetium-99 continues to give off beta rays for millions of years. Thus, a particular nucleus might disintegrate the next instant or several million years later. The rate of this radioactive decay cannot be changed by varying the temperature, the pressure, or the chemical environment of the technetium nucleus. Radioactivity, whether from technetium or some other nucleus, is not affected by the variables that affect the rate of a chemical reaction. In this section, we will look at how to express quantitatively the rate of radioactive decay.

### Rate of Radioactive Decay and Half-Life

The rate of radioactive decay—that is, the number of nuclei disintegrating per unit time—is found to be proportional to the number of radioactive nuclei in the sample. You can express this rate mathematically as

$$\text{Rate} = kN_t$$

Here  $N_t$  is the number of radioactive nuclei at time  $t$ , and  $k$  is the **radioactive decay constant**, or *rate constant for radioactive decay*. This rate constant is a characteristic of the radioactive nuclide, each nuclide having a different value. ►

You can obtain the decay constant for a radioactive nucleus by counting the nuclear disintegrations over a period of time. The original definition of the curie (now  $3.7 \times 10^{10}$  disintegrations per second) was the activity or decay rate of 1.0 g of radium-226. You can use this with the rate equation to obtain the decay constant of radium-226. Radium-226 has a molar mass of 226 g. A 1.0-g sample of radium-226 contains the following number of nuclei:

$$1.0 \text{ g Ra-226} \times \frac{1 \text{ mol Ra-226}}{226 \text{ g Ra-226}} \times \frac{6.02 \times 10^{23} \text{ Ra-226 nuclei}}{1 \text{ mol Ra-226}} = 2.7 \times 10^{21} \text{ Ra-226 nuclei}$$

This equals the value of  $N_t$ . When you solve  $\text{Rate} = kN_t$  for  $k$ , you get

$$k = \frac{\text{rate}}{N_t}$$

Substituting into this gives

$$k = \frac{3.7 \times 10^{10} \text{ nuclei/s}}{2.7 \times 10^{21} \text{ nuclei}} = 1.4 \times 10^{-11}/\text{s} \text{ ►}$$

The rate equation for radioactive decay has the same form as the rate law for a first-order chemical reaction. Indeed, radioactive decay is a first-order rate process, and the mathematical relationships used in Chapter 13 for first-order reactions apply here also.

Recall from Chapter 7 that /s is equivalent to the unit  $\text{s}^{-1}$ .

### Example 20.7 Calculating the Decay Constant from the Activity

#### Gaining Mastery Toolbox

##### Critical Concept 20.7

The radioactive decay constant ( $k$ ) is independent of the amount of radioactive material and depends only on the identity of the nuclide. Different nuclides have different decay constants. The rate of radioactive decay depends upon the decay constant and the *number* of radioactive nuclei at a particular time ( $N_t$ ). The rate of nuclear decay is proportional to the number of radioactive nuclei in a sample, expressed mathematically as  $\text{Rate} = kN_t$ .

##### Solution Essentials:

- Curie (Ci)
- Activity
- Radioactive decay constant
- Radioactive decay equation ( $\text{Rate} = kN_t$ )
- Nuclear equation
- Nuclide symbol

A 1.0-mg sample of technetium-99 has an activity of  $1.7 \times 10^{-5}$  Ci (Ci = curies), decaying by beta emission. What is the decay constant for  ${}_{43}^{99}\text{Tc}$ ?

**Problem Strategy** Solve the equation  $\text{Rate} = kN_t$  for  $k$ ; obtain Rate and  $N_t$  from values in the problem statement. The rate of decay (Rate) of Tc-99 equals the activity in curies expressed as nuclei decaying per second, noting that  $1 \text{ Ci} = 3.7 \times 10^{10} \text{ nuclei/s}$ . Obtain the number of Tc-99 nuclei,  $N_t$ , by converting  $1.0 \times 10^{-3}$  g of Tc-99 as follows:

For the first conversion, note that the numerical value of the molar mass of Tc-99 is approximately equal to the mass number of Tc(99).

**Solution** The rate of decay in this sample is

$$\text{Rate} = 1.7 \times 10^{-5} \text{ Ci} \times \frac{3.7 \times 10^{10} \text{ nuclei/s}}{1.0 \text{ Ci}} = 6.3 \times 10^5 \text{ nuclei/s}$$

The number of nuclei in this sample of  $1.0 \times 10^{-3}$  g  ${}_{43}^{99}\text{Tc}$  is

$$1.0 \times 10^{-3} \text{ g Tc-99} \times \frac{1 \text{ mol Tc-99}}{99 \text{ g Tc-99}} \times \frac{6.02 \times 10^{23} \text{ Tc-99 nuclei}}{1 \text{ mol Tc-99}} = 6.1 \times 10^{18} \text{ Tc-99 nuclei}$$

The decay constant is

$$k = \frac{\text{rate}}{N_t} = \frac{6.3 \times 10^5 \text{ nuclei/s}}{6.1 \times 10^{18} \text{ nuclei}} = 1.0 \times 10^{-13}/\text{s}$$

**Answer Check** You should typically expect decay constants to range from  $10^{-16}/\text{s}$  to  $10^{-3}/\text{s}$ , so anything outside this range should be carefully checked.

**Exercise 20.7** The nucleus  ${}_{43}^{99m}\text{Tc}$  is a metastable nucleus of technetium-99; it is used in medical diagnostic work. Technetium-99 $m$  decays by emitting gamma rays. A 2.5- $\mu\text{g}$  (microgram) sample has an activity of 13 Ci. What is the decay constant (in units of /s)?

See Problems 20.57, 20.58, 20.59, and 20.60.

**Figure 20.13** ▶

**Radioactive decay of a 1.000-g sample of iodine-131** The sample decays by one-half in each half-life of 8.07 days.

We define the **half-life** of a radioactive nucleus as *the time it takes for one-half of the nuclei in a sample to decay*. ◀ The half-life is independent of the amount of sample. In some cases, you can find the half-life of a radioactive sample by directly observing how long it takes for one-half of the sample to decay. For example, you find that 1.000 g of iodine-131, an isotope used in treating thyroid cancer, decays to 0.500 g in 8.07 days. ◀ Thus, its half-life is 8.07 days. In another 8.07 days, this sample would decay to one-half of 0.500 g, or 0.250 g, and so forth. Figure 20.13 shows this decay pattern.

Although you might be able to obtain the half-life of a radioactive nucleus by direct observation in some cases, this is impossible for many nuclei because they decay too quickly or too slowly. Uranium-238, for example, has a half-life of 4.51 billion years, much too long to be directly observed! The usual method of determining the half-life is by measuring decay rates and relating them to half-lives.

You relate the half-life for radioactive decay,  $t_{1/2}$ , to the decay constant  $k$  by the equation

$$t_{1/2} = \frac{0.693}{k}$$

The next example illustrates the use of this relation.

### Example 20.8 Calculating the Half-Life from the Decay Constant

#### Gaining Mastery Toolbox

##### Critical Concept 20.8

The half-life of a nuclide undergoing nuclear decay is the time it takes for one-half of the nuclei in the sample to decay. The half-life of a sample is independent of the amount of radioactive material and depends only upon the decay constant of the nuclide in the sample.

##### Solution Essentials:

- Half-life equation for nuclear decay ( $t_{1/2} = \frac{0.693}{k}$ )
- Half-life
- Radioactive decay constant

The decay constant for the beta decay of  $^{99}_{43}\text{Tc}$  was obtained in Example 20.7. We found that  $k$  equals  $1.0 \times 10^{-13}/\text{s}$ . What is the half-life of this isotope in years?

**Problem Strategy** Because the decay constant is given in the problem, the preceding equation can be used to calculate the half-life ( $t_{1/2}$ ) from  $k$ .

**Solution** Substitute the value of  $k$  into the preceding equation.

$$t_{1/2} = \frac{0.693}{k} = \frac{0.693}{1.0 \times 10^{-13}/\text{s}} = 6.9 \times 10^{12} \text{ s}$$

Then you convert this half-life in seconds to years.

$$6.9 \times 10^{12} \text{ s} \times \frac{1 \text{ min}}{60 \text{ s}} \times \frac{1 \text{ h}}{60 \text{ min}} \times \frac{1 \text{ d}}{24 \text{ h}} \times \frac{1 \text{ y}}{365 \text{ d}} = 2.2 \times 10^5 \text{ y}$$

**Answer Check** Note the inverse relationship between the decay constant and the half-life; those compounds with very small decay constants have very long half-lives.

**Exercise 20.8** Cobalt-60, used in cancer therapy, decays by beta and gamma emission. The decay constant is  $4.18 \times 10^{-9}/\text{s}$ . What is the half-life in years?

See Problems 20.61 and 20.62.

The half-life of a reaction was discussed in Section 13.4.

Iodine is attracted to the thyroid gland, which incorporates the element into the growth hormone thyroxine. Radiation from iodine-131 kills cancer cells in the thyroid gland.

Tables of radioactive nuclei often list the half-life. When you want the decay constant or the activity of a sample, you can calculate them from the half-life. This calculation is illustrated in the next example.

### Example 20.9 Calculating the Decay Constant and Activity from the Half-Life

#### Gaining Mastery Toolbox

##### Critical Concept 20.9

The half-life of a nuclide undergoing nuclear decay is the time it takes for one-half of the nuclei in the sample to decay. The half-life of a sample is independent of the amount of radioactive material and depends only upon the decay constant of the nuclide in the sample.

##### Solution Essentials:

- Half-life equation for nuclear decay ( $t_{1/2} = \frac{0.693}{k}$ )
- Half-life
- Curie (Ci)
- Radioactive decay constant
- Radioactive decay equation (Rate =  $kN_t$ )
- Nuclide symbol

Tritium,  ${}^3_1\text{H}$ , is a radioactive nucleus of hydrogen. It is used in luminous watch dials. Tritium decays by beta emission with a half-life of 12.3 years. What is the decay constant (in /s)? What is the activity (in Ci) of a sample containing  $2.5 \mu\text{g}$  of tritium? The atomic mass of  ${}^3_1\text{H}$  is 3.02 amu.

**Problem Strategy** First convert the half-life to its value in seconds and then calculate  $k$ . Then you can use the rate equation to find the rate of decay of the sample (in nuclei/s) and finally the activity.

**Solution** The conversion of the half-life to seconds gives

$$12.3 \text{ y} \times \frac{365 \text{ d}}{1 \text{ y}} \times \frac{24 \text{ h}}{1 \text{ d}} \times \frac{60 \text{ min}}{1 \text{ h}} \times \frac{60 \text{ s}}{1 \text{ min}} = 3.88 \times 10^8 \text{ s}$$

Because  $t_{1/2} = 0.693/k$ , you solve this for  $k$  and substitute the half-life in seconds.

$$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{3.88 \times 10^8 \text{ s}} = 1.79 \times 10^{-9}/\text{s}$$

Before substituting into the rate equation, you need to know the number of tritium nuclei in a sample containing  $2.5 \times 10^{-6} \text{ g}$  of tritium. You get

$$2.5 \times 10^{-6} \text{ g H-3} \times \frac{1 \text{ mol H-3}}{3.02 \text{ g H-3}} \times \frac{6.02 \times 10^{23} \text{ H-3 nuclei}}{1 \text{ mol H-3}} = 5.0 \times 10^{17} \text{ H-3 nuclei}$$

Now you substitute into the rate equation.

$$\text{Rate} = kN_t = 1.79 \times 10^{-9}/\text{s} \times 5.0 \times 10^{17} \text{ nuclei} = 9.0 \times 10^8 \text{ nuclei/s}$$

You obtain the activity of the sample by converting the rate in disintegrations of nuclei per second to curies.

$$\text{Activity} = 9.0 \times 10^8 \text{ nuclei/s} \times \frac{1.0 \text{ Ci}}{3.7 \times 10^{10} \text{ nuclei/s}} = 0.024 \text{ Ci}$$

**Answer Check** Note that the answer is a relatively small activity (0.024 Ci). If we consider the very small size of the sample of tritium ( $2.5 \mu\text{g}$ ), we should expect an answer of this magnitude.

**Exercise 20.9** Strontium-90,  ${}^{90}_{38}\text{Sr}$ , is a radioactive decay product of nuclear fallout from nuclear weapons testing. Because of its chemical similarity to calcium, it is incorporated into the bones if present in food. The half-life of strontium-90 is 28.1 y. What is the decay constant of this isotope? What is the activity of a sample containing 5.2 ng ( $5.2 \times 10^{-9} \text{ g}$ ) of strontium-90?

See Problems 20.63, 20.64, 20.65, and 20.66.

Once you know the decay constant for a radioactive isotope, you can calculate the fraction of the radioactive nuclei that remains after a given period of time by the following equation. ►

$$\ln \frac{N_t}{N_0} = -kt$$

Here  $N_0$  is the number of nuclei in the original sample ( $t = 0$ ). After a period of time  $t$ , the number of nuclei decreases by decay to the number  $N_t$ . The fraction of nuclei remaining after time  $t$  is  $N_t/N_0$ . The next example illustrates the use of this equation.

A similar equation is given in Chapter 13 for the reactant concentration at time  $t$ ,  $[A]_t$

$$\ln \frac{[A]_t}{[A]_0} = -kt$$

where  $[A]_0$  is the concentration of  $A$  at  $t = 0$ .

**Example 20.10** Determining the Fraction of Nuclei Remaining after a Specified Time**Gaining Mastery Toolbox****Critical Concept 20.10**

The decay constant can be used to determine the amount of radioactive material that remains after a period of time has elapsed. The fraction of material that remains after a period of time has elapsed ( $t$ ) is the ratio of the number of radioactive nuclei ( $N_t$ ) to the number of radioactive nuclei in the original sample when the time measurement started ( $N_0$ ). This fraction is often expressed as a percent.

**Solution Essentials:**

- Equation relating fraction of nuclei after time has elapsed to the decay constant  $\left(\ln \frac{N_t}{N_0} = -kt\right)$
- Half-life equation for nuclear decay ( $t_{1/2} = \frac{0.693}{k}$ )
- Half-life
- Radioactive decay constant
- Nuclide symbol

Phosphorus-32 is a radioactive isotope with a half-life of 14.3 d (d = days). A biochemist has a vial containing a compound of phosphorus-32. If the compound is used in an experiment 5.5 d after the compound was prepared, what fraction of the radioactive isotope originally present remains? Suppose the sample in the vial originally contained 0.28 g of phosphorus-32. How many grams remain after 5.5 d?

**Problem Strategy** In the first part of the problem, we are asked to determine what fractional amount of radioactive P-32 in a compound remains after 5.5 d. For this, we can use the preceding equation. Once we know the fractional amount of P-32 that remains, we can multiply this quantity by the original amount of compound (0.28 g) to find the mass of compound that remains after 5.5 d.

**Solution** If  $N_0$  is the original number of P-32 nuclei in the vial and  $N_t$  is the number after 5.5 d, the fraction remaining is  $N_t/N_0$ . You can obtain this fraction from the equation

$$\ln \frac{N_t}{N_0} = -kt$$

You substitute  $k = 0.693/t_{1/2}$ .

$$\ln \frac{N_t}{N_0} = \frac{-0.693t}{t_{1/2}}$$

Because  $t = 5.5$  d and  $t_{1/2} = 14.3$  d, you obtain

$$\ln \frac{N_t}{N_0} = \frac{-0.693 \times 5.5 \text{ d}}{14.3 \text{ d}} = -0.267$$

(An additional digit has been retained for further calculation.) Hence,

$$\text{Fraction nuclei remaining} = \frac{N_t}{N_0} = e^{-0.267} = \mathbf{0.77}$$

(Note that 0.766 is rounded to two significant figures.) Thus, 77% of the nuclei remain. The mass of  $^{32}_{15}\text{P}$  in the vial after 5.5 d is

$$0.28 \text{ g} \times 0.766 = \mathbf{0.21 \text{ g}}$$

**Answer Check** After one half-life of 14.3 days, only one-half of the sample would be left. Since only 5.5 days have elapsed, which is less than the half-life, you should expect less than half of the 0.28 g sample to have decayed. This means that there should be more than 0.14 g remaining, which is the case. For any problems of this type, this approach is an effective method for quickly checking your answers.

**Exercise 20.10** A nuclear power plant emits into the atmosphere a very small amount of krypton-85, a radioactive isotope with a half-life of 10.76 y. What fraction of this krypton-85 remains after 25.0 y?

See Problems 20.69 and 20.70.

**Radioactive Dating**

Fixing the dates of relics and stone implements or pieces of charcoal from ancient campsites is an application based on radioactive decay rates. Because the rate of radioactive decay of a nuclide is constant, this rate can serve as a clock for dating very old rocks and human implements. Dating wood and similar carbon-containing objects that are several thousand to fifty thousand years old can be done with radioactive carbon, carbon-14, which has a half-life of 5730 y.

Carbon-14 is present in the atmosphere as a result of cosmic-ray bombardment of earth. Cosmic rays are radiations from space that consist of protons and alpha particles, as well as heavier ions. These radiations produce other kinds of particles,

including neutrons, as they bombard the upper atmosphere. The collision of a neutron with a nitrogen-14 nucleus (the most abundant nitrogen nuclide) can produce a carbon-14 nucleus.

Carbon dioxide containing carbon-14 mixes with the lower atmosphere. Because of the constant production of  ${}^{14}_6\text{C}$  and its radioactive decay, a small, constant fractional abundance of carbon-14 is maintained in the atmosphere.

Living plants, which continuously use atmospheric carbon dioxide, also maintain a constant abundance of carbon-14. Similarly, living animals, by feeding on plants, have a constant fractional abundance of carbon-14. But once an organism dies, it is no longer in chemical equilibrium with atmospheric  $\text{CO}_2$ . The ratio of carbon-14 to carbon-12 begins to decrease by radioactive decay of carbon-14. In this way, this ratio of carbon isotopes becomes a clock measuring the time since the death of the organism.

If you assume that the ratio of carbon isotopes in the lower atmosphere has remained at the present level for the last 50,000 years (presently 1 out of  $10^{12}$  carbon atoms is carbon-14), you can deduce the age of any dead organic object by measuring the level of beta emissions that arise from the radioactive decay of carbon-14. ▶ This is the decay reaction:

In this way, bits of campfire charcoal, parchment, jawbones, and the like have been dated.

Analyses of tree rings have shown that this assumption is not quite valid. Before 1000 B.C., the levels of carbon-14 were somewhat higher than they are today. Moreover, recent human activities (burning of fossil fuels and atmospheric nuclear testing) have changed the fraction of carbon-14 in atmospheric  $\text{CO}_2$ .

### Example 20.11 Applying the Carbon-14 Dating Method

#### Gaining Mastery Toolbox

##### Critical Concept 20.11

Radioactive dating requires that we know the starting amount of the radioactive isotope ( $N_0$ ) when the material was created, the current amount of radioactive isotope ( $N_t$ ), and the half-life of the radioactive isotope. For carbon-14 dating, we assume that the amount of carbon-14 in a living organism has remained constant during the past 50,000 years; therefore, we know the starting amount of carbon-14 ( $N_t$ ) of any plants that were alive during the last 50,000 years.

##### Solution Essentials:

- Radioactive dating
- Equation relating fraction of nuclei after time has elapsed to the decay constant  $\left(\ln \frac{N_t}{N_0} = -kt\right)$
- Half-life equation for nuclear decay  $\left(t_{1/2} = \frac{0.693}{k}\right)$
- Half-life
- Radioactive decay constant
- Nuclide symbol

A piece of charcoal from a tree killed by the volcanic eruption that formed the crater in Crater Lake (in Oregon) gave 7.0 disintegrations of carbon-14 nuclei per minute per gram of total carbon. Present-day carbon (in living matter) gives 15.3 disintegrations per minute per gram of total carbon. Determine the date of the volcanic eruption. Recall that the half-life of carbon-14 is 5730 y.

**Problem Strategy** The solution to the problem is determining the amount of time ( $t$ ) that it takes for the amount of carbon-14 in the living sample ( $N_0$ ) to decrease to the amount present today ( $N_t$ ). The equation  $\ln \frac{N_t}{N_0} = -kt$  relates these quantities; however, we do not have the decay constant ( $k$ ), and thus, you cannot directly use this equation to determine the elapsed time. However, the half-life of carbon-14 is given in the problem so that we can employ the relationship between the decay constant and the half-life of carbon-14 to solve first for the decay constant,  $k = 0.693/t_{1/2}$ , and then substitute the value for the decay constant into the equation  $\ln \frac{N_t}{N_0} = -kt$ .

Recognizing that the process described above is a combination of equations, we can do some algebra to simplify our solving the problem.

Start with

$$\ln \frac{N_t}{N_0} = -kt$$

substitute  $k = 0.693/t_{1/2}$  into the preceding equation to yield

$$\ln \frac{N_t}{N_0} = 0.693t/t_{1/2}$$

Rearranging the equation to solve for  $t$  yields

$$t = t_{1/2}/0.693 \ln \frac{N_t}{N_0} \quad (\text{continued})$$

**Example 20.11** (continued)

To get  $N_0/N_t$ , you assume that the ratio of  $^{14}_6\text{C}$  to  $^{12}_6\text{C}$  in the atmosphere has remained constant. Then you can say that 1.00 g of total carbon from the living tree gave 15.3 disintegrations per minute. The ratio of the number of  $^{14}_6\text{C}$  nuclei originally present to the number that existed at the time of dating equals the ratio of rates of disintegration.

**Solution** The ratio of rates of disintegration is

$$\frac{N_0}{N_t} = \frac{15.3}{7.0} = 2.2$$

Substituting this value of  $N_0/N_t$  and  $t_{1/2} = 5730$  y into the equation developed in the Problem Strategy gives

$$t = \frac{t_{1/2}}{0.693} \ln \frac{N_0}{N_t} = \frac{5730 \text{ y}}{0.693} \ln 2.2 = 6.5 \times 10^3 \text{ y}$$

Thus, the date of the eruption was about **4500 B.C.**, 6500 years ago.

**Answer Check** You can obtain a quick check by comparing the disintegration rate expected after various half-lives. For example, the original rate is 15.3 disintegrations per minute, whereas the rate after half the sample decays is one-half this, or 7.6 disintegrations per minute. (After two half-lives, the disintegration rate is one-half of 7.6, or 3.8 disintegrations per minute.) Thus, a rate of 7.0 disintegrations per minute is expected to occur at a time somewhat greater than the half-life of carbon-14 (that is, somewhat greater than 5730 y).

**Exercise 20.11** A jawbone from the archaeological site at Folsom, New Mexico, was dated by analysis of its radioactive carbon. The activity of the carbon from the jawbone was 4.5 disintegrations per minute per gram of total carbon. What was the age of the jawbone? Carbon from living material gives 15.3 disintegrations per minute per gram of carbon.

See Problems 20.75 and 20.76.

For the age of rocks and meteorites, other, similar methods of dating have been used. One method depends on the radioactivity of naturally occurring potassium-40, which decays by positron emission and electron capture (as well as by beta emission).

Potassium occurs in many rocks. Once such a rock forms by solidification of molten material, the argon from the decay of potassium-40 is trapped. To obtain the age of a rock, you first determine the number of  $^{40}_{19}\text{K}$  atoms and the number of  $^{40}_{18}\text{Ar}$  atoms in a sample. The number of  $^{40}_{19}\text{K}$  atoms equals  $N_t$ . The number originally present,  $N_0$ , equals  $N_t$  plus the number of argon atoms, because each argon atom resulted from the decay of a  $^{40}_{19}\text{K}$  nucleus. You then calculate the age of the rock from the ratio  $N_t/N_0$ .

The oldest rocks on earth have been dated at  $3.8 \times 10^9$  y. The rocks at the earth's surface have been subjected to extensive weathering, so even older rocks may have existed. This age,  $3.8 \times 10^9$  y, therefore represents the minimum possible age of the earth—the time since the solid crust first formed. Ages of meteorites, assumed to have solidified at the same time as other solid objects in the solar system, including earth, have been determined to be  $4.4 \times 10^9$  y to  $4.6 \times 10^9$  y. It is now believed from this and other evidence that the age of the earth is  $4.6 \times 10^9$  y.

**CONCEPT CHECK 20.3**

Why do you think that carbon-14 dating is limited to less than 50,000 years?

## 20.5 Applications of Radioactive Isotopes

We have already described two applications of nuclear chemistry. One was the preparation of elements not available naturally. We noted that the discovery of the transuranium elements clarified the position of the heavy elements in the periodic table. In the section just completed, we discussed the use of radioactivity in dating objects. We will discuss practical uses of nuclear energy later in the chapter. Here we will look at the applications of radioactive isotopes to chemical analysis and to medicine.

### Chemical Analysis

A **radioactive tracer** is a very small amount of radioactive isotope added to a chemical, biological, or physical system to study the system. The advantage of a radioactive tracer is that it behaves chemically just as a nonradioactive isotope does, but it can be detected in exceedingly small amounts by measuring the radiations emitted.

As an illustration of the use of radioactive tracers, consider the problem of establishing that chemical equilibrium is a dynamic process. Let us look at the equilibrium of solid lead(II) iodide and its saturated solution, containing  $\text{Pb}^{2+}(aq)$  and  $\text{I}^{-}(aq)$ . The equilibrium is

In two separate beakers, you prepare saturated solutions of  $\text{PbI}_2$  in contact with the solid. One beaker contains only natural iodine atoms with nonradioactive isotopes. The other beaker contains radioactive iodide ion,  $^{131}\text{I}^{-}$ . Some of the solution, but no solid, containing the radioactive iodide ion is now added to the beaker containing nonradioactive iodide ion. Both solutions are saturated, so the amount of solid in this beaker remains constant. Yet after a time the solid lead iodide, which was originally nonradioactive, becomes radioactive. This is evidence for a dynamic equilibrium, in which radioactive iodide ions in the solution substitute for nonradioactive iodide ions in the solid.

With only naturally occurring iodine available, it would have been impossible to detect the dynamic equilibrium. By using  $^{131}\text{I}^{-}$  as a radioactive tracer, you can easily follow the substitution of radioactive iodine into the solid by measuring its increase in radioactivity.

A series of experiments using tracers was carried out in the late 1950s by Melvin Calvin at the University of California, Berkeley, to discover the mechanism of photosynthesis in plants. ▶ The overall process of photosynthesis involves the reaction of  $\text{CO}_2$  and  $\text{H}_2\text{O}$  to give glucose,  $\text{C}_6\text{H}_{12}\text{O}_6$ , and  $\text{O}_2$ . Energy for photosynthesis comes from the sun.

This equation represents only the net result of photosynthesis. As Calvin was able to show, the actual process consists of many separate steps. In several experiments, algae (single-celled plants) were exposed to carbon dioxide containing much more radioactive carbon-14 than occurs naturally. Then the algae were extracted with a solution of alcohol and water. The various compounds in this solution were separated by chromatography and identified. ▶ Compounds that contained radioactive carbon were produced in the different steps of photosynthesis. Eventually, Calvin was able to use tracers to show the main steps in photosynthesis.

Another example of the use of radioactive tracers in chemistry is **isotope dilution**, a technique to determine the quantity of a substance in a mixture or of the total volume of solution by adding a known amount of an isotope to it. After removal of a portion of the mixture, the fraction by which the isotope has been diluted provides a way of determining the quantity of substance or volume of solution.

As an example, suppose you wish to obtain the volume of water in a tank but are unable to drain the tank. You add 100 mL of water containing a radioactive isotope. After allowing this to mix completely with the water in the tank, you

Melvin Calvin received the Nobel Prize in Chemistry in 1961 for his work on photosynthesis.

Chromatography was discussed in the essay at the end of Section 1.4.

withdraw 100 mL of solution from the tank. You find that the activity of this solution in curies is 1/1000 that of the original radioactive solution. The isotope has been diluted by a factor of 1000, so the volume of the tank is  $1000 \times 100 \text{ mL} = 100,000 \text{ mL}$  (100 L).

A typical chemical example of isotope dilution is the determination of the amount of vitamin B<sub>12</sub>, a cobalt-containing substance, in a sample of food. Although part of the vitamin in food can be obtained in pure form, not all of the vitamin can be separated. Therefore, you cannot precisely determine the quantity of vitamin B<sub>12</sub> in a sample of food by separating the pure vitamin and weighing it. But you can determine the amount of vitamin B<sub>12</sub> by isotope dilution. Suppose you add  $2.0 \times 10^{-7} \text{ g}$  of vitamin B<sub>12</sub> containing radioactive cobalt-60 to 125 g of food and mix well. You then separate  $5.4 \times 10^{-7} \text{ g}$  of pure vitamin B<sub>12</sub> from the food and find that the activity in curies of this quantity of the vitamin contains 5.6% of the activity added from the radioactive cobalt. This indicates that you have recovered 5.6% of the total amount of vitamin B<sub>12</sub> in the sample. Therefore, the mass of vitamin B<sub>12</sub> in the food, including the amount added ( $2.0 \times 10^{-7} \text{ g}$ ), is

$$5.4 \times 10^{-7} \text{ g} \times \frac{100}{5.6} = 9.6 \times 10^{-6} \text{ g}$$

Subtracting the amount added in the analysis gives

$$9.6 \times 10^{-6} \text{ g} - 2.0 \times 10^{-7} \text{ g} = 9.4 \times 10^{-6} \text{ g}$$

**Neutron activation analysis** is an analysis of elements in a sample based on the conversion of stable isotopes to radioactive isotopes by bombarding a sample with neutrons. Human hair contains trace amounts of many elements. By determining the exact amounts and the position of the elements in the hair shaft, you can identify whom the hair comes from (assuming you have a sample known to be that person's hair for comparison). Consider the analysis of human hair for arsenic, for example. When the natural isotope  ${}^{75}_{33}\text{As}$  is bombarded with neutrons, a metastable nucleus  ${}^{76m}_{33}\text{As}$  is obtained.

A metastable nucleus is in an excited state. It decays, or undergoes a transition, to a lower state by emitting gamma rays. The frequencies, or energies, of the gamma rays emitted are characteristic of the element and serve to identify it. Also, the intensities of the gamma rays emitted are proportional to the amount of the element present. The method is very sensitive; it can identify as little as  $10^{-9} \text{ g}$  of arsenic. ◀

### Medical Therapy and Diagnosis

The use of radioactive isotopes has had a profound effect on the practice of medicine. Radioisotopes were first used in medicine in the treatment of cancer. This treatment is based on the fact that rapidly dividing cells, such as those in cancer, are more adversely affected by radiation from radioactive substances than are cells that divide more slowly. Radium-226 and its decay product radon-222 were used for cancer therapy a few years after the discovery of radioactivity. Today gamma radiation from cobalt-60 is more commonly used.

Cancer therapy is only one of the ways in which radioactive isotopes are used in medicine. The greatest advances in the use of radioactive isotopes have been in the diagnosis of disease. Radioactive isotopes are used for diagnosis in two ways. They are used to develop images of internal body organs so that their functioning can be examined. And they are used as tracers in the analysis of minute amounts of substances, such as a growth hormone in blood, to deduce possible disease conditions.

Technetium-99m is the radioactive isotope used most often to develop images (pictures) of internal body organs. It has a half-life of 6.02 h, decaying by

Neutron activation analysis has been used to authenticate oil paintings by giving an exact analysis of pigments used. Pigment compositions have changed, so it is possible to detect fraudulent paintings done with more modern pigments. The analysis can be done without affecting the painting.

gamma emission to technetium-99 in its nuclear ground state. The image is prepared by scanning part of the body for gamma rays with a scintillation detector. (Figure 20.1 shows the image of a person's skeleton obtained with technetium-99m.)

The technetium isotope is produced in a special container, or generator, shown in Figure 20.14. The generator contains radioactive molybdate ion,  $\text{MoO}_4^{2-}$ , adsorbed on alumina granules. Radioactive molybdenum-99 is produced from uranium-235 nuclear fission products (see Section 20.7). This radioactive molybdenum, adsorbed on alumina, is placed in the generator and sent to the hospital. Pertechnetate ion is obtained when the molybdenum-99 nucleus in  $\text{MoO}_4^{2-}$  decays. The nuclear equation is

Each day pertechnetate ion,  $\text{TcO}_4^-$ , is leached from the generator with a salt solution whose osmotic pressure is the same as that of blood. One use of this pertechnetate ion is in assessing the performance of a patient's heart. The physician injects tin(II) ion into a vein and, a few minutes later, administers a similar injection of the pertechnetate ion. In the presence of tin(II) ion, the pertechnetate ion binds to the red blood cells. The heart then becomes visible in gamma-ray imaging equipment, because of the quantity of blood in the heart. Technetium-99m pyrophosphate ( $\text{Tc}_2\text{P}_2\text{O}_7$ ) is another technetium species useful for gamma-ray imaging. This compound binds especially strongly to recently damaged heart muscle, so these gamma-ray images can be used to assess the extent of damage from a heart attack.

**b** A series of cross-sectional images of a patient's heart after exercise and then some time afterward. By comparing the stress and rest images, a physician can see if there is impaired blood flow to an area of the heart (the area is dark in the stress image but light in the rest image) or if the heart muscle has been damaged through a heart attack (the area is dark in both stress and rest images).

### Figure 20.15 ▲

#### Using thallium-201 to diagnose heart disease

Thallium-201 is a radioisotope used to determine whether a person has heart disease (caused by narrowing of the arteries to the heart). This isotope decays by electron capture and emits X rays and gamma rays, which can be used to obtain images similar to those obtained from technetium-99m (Figure 20.15). Thallium-201 injected into the blood binds particularly strongly to heart muscle. Diagnosis of heart disease depends on the fact that only tissue that receives sufficient blood flow binds thallium-201. When someone exercises strenuously, some part of the person's heart tissue may not receive sufficient blood because of narrowed arteries. These areas do not bind thallium-201 and show up on an image as dark spots.

More than a hundred different radioactive isotopes have been used in medicine. Besides technetium-99m and thallium-201, other examples include iodine-131, used to measure thyroid activity; phosphorus-32, used to locate tumors; and iron-59, used to measure the rate of formation of red blood cells.

*Radioimmunoassay* is a technique for analyzing blood and other body fluids for very small quantities of biologically active substances. The technique depends on the reversible binding of the substance to an antibody. Antibodies are produced in animals as protection against foreign substances. They protect by binding to the substance and countering its biological activity. Consider, for example, the analysis for insulin in a sample of blood from a patient. Before the analysis, a solution of insulin-binding antibodies has been prepared from laboratory animals. This solution is combined with insulin containing a radioactive isotope, in which the antibodies bind with radioactive insulin. Now the blood sample containing an unknown amount of insulin is added to the antibody–radioactive insulin mixture. The nonradioactive insulin replaces some of the radioactive insulin bound to the antibody. As a result, the antibody loses some of its radioactivity. The loss in radioactivity can be related to the amount of insulin in the blood sample.

## Positron Emission Tomography (PET)

Positron emission tomography (PET) is a technique for following biochemical processes within the organs (brain, heart, and so forth) of the human body. Like magnetic resonance imaging (see essay at the end of Section 8.1), a PET scan produces an image of a two-dimensional slice through a body organ of a patient. The image shows the distribution of some positron-emitting isotope present in a compound that was administered earlier by injection. By comparing the PET scan of the patient with that of a healthy subject, a physician can diagnose the presence or absence of disease (Figure 20.16). The PET scan of the brain of an Alzheimer's patient differs markedly from that of a healthy subject. Similarly, the PET scan of a patient with a heart damaged by a coronary attack clearly shows the damaged area. Moreover, the PET scan may help the physician assess the likelihood of success of bypass surgery.

Some isotopes used in PET scans are carbon-11, nitrogen-13, oxygen-15, and fluorine-18. All have short half-lives, so the radiation dosage to the patient is minimal.

However, because of the short half-life, a chemist must prepare the diagnostic compound containing the radioactive nucleus shortly before the physician administers it. The preparation of this compound requires a cyclotron, whose cost (several million dollars) is a major deterrent to the general use of PET scans.

Figure 20.17 shows a patient undergoing a PET scan of the brain. The instrument actually detects gamma radiation. When a nucleus emits a positron within the body, the positron travels only a few millimeters before it reacts with an electron. This reaction is an example of the annihilation of matter (an electron) by antimatter (a positron). Both the electron and the positron disappear and produce two gamma photons. The gamma photons easily pass through human tissue, so they can be recorded by scintillation detectors placed around the body. You can see the circular bank of detectors in Figure 20.17. The detectors record the distribution of gamma radiation, and from this information a computer constructs images that can be used by the physician.

**Figure 20.16** ▲

**PET scans of normal and schizophrenic patients** Colored positron emission tomography (PET) brain scans of a schizophrenic (bottom) versus normal patient (top), speaking. The red/yellow highlighted areas are active when patients generate words. In the schizophrenic brain, there is additional brain activity not seen in normal subjects. Schizophrenic patients can suffer from delusions and depression.

**Figure 20.17** ▲

■ See Problems 20.105 and 20.106.

## ► Energy of Nuclear Reactions

Nuclear reactions, like chemical reactions, involve changes of energy. However, the changes of energy in nuclear reactions are enormous by comparison with those in chemical reactions. The energy released by certain nuclear reactions is used in nuclear power reactors and to provide the energy for nuclear weapons. In the case of a power plant, the energy from the reactions is released in controlled, small amounts by the fission of uranium-235. With a nuclear weapon, the objective is to release the energy as rapidly as possible and produce a nuclear explosion. Although the source of energy for nuclear power plants and weapons can be the same, a typical nuclear power plant does not contain enough fissionable material in high enough concentration to produce a nuclear explosion.

### 20.6 Mass–Energy Calculations

When nuclei decay, they form products of lower energy. The change of energy is related to changes of mass, according to the mass–energy equivalence relation derived by Albert Einstein in 1905. Using this relation, you can obtain the energies of nuclear reactions from mass changes.

#### Mass–Energy Equivalence

One of the conclusions from Einstein's theory of special relativity is that the mass of a particle changes with its speed: the greater the speed, the greater the mass. Or, because kinetic energy depends on speed, the greater the kinetic energy of a particle, the greater its mass. This result, according to Einstein, is even more general. Energy and mass are equivalent and are related by the equation

$$E = mc^2$$

Here  $c$  is the speed of light,  $3.00 \times 10^8$  m/s.

The meaning of this equation is that for any mass there is an associated energy, or for any energy there is an associated mass. If a system loses energy, it must also lose mass. For example, when carbon burns in oxygen, it releases heat energy.

Because this chemical system loses energy, it should also lose mass. In principle, you could obtain  $\Delta H$  for the reaction by measuring the change in mass and relating this by Einstein's equation to the change in energy. ◀ However, weight measurements are of no practical value in determining heats of reaction—the changes in mass are simply too small to detect.

Calculation of the mass change for a typical chemical reaction, the burning of carbon in oxygen, will show just how small this quantity is. When the energy changes by an amount  $\Delta E$ , the mass changes by an amount  $\Delta m$ . You can write Einstein's equation in the form

$$\Delta E = (\Delta m)c^2$$

The change in energy when 1 mol of carbon reacts is  $-3.935 \times 10^5$  J, or  $-3.935 \times 10^5$  kg·m<sup>2</sup>/s<sup>2</sup>. Hence,

$$\Delta m = \frac{\Delta E}{c^2} = \frac{-3.935 \times 10^5 \text{ kg}\cdot\text{m}^2/\text{s}^2}{(3.00 \times 10^8 \text{ m/s})^2} = -4.37 \times 10^{-12} \text{ kg}$$

For comparison, a good analytical balance can detect a mass as small as  $1 \times 10^{-7}$  kg, but this is ten thousand times greater than the mass change caused by the release of heat during the combustion of 1 mol of carbon.

The change in mass gives the change in internal energy,  $\Delta U$ . The enthalpy change,  $\Delta H$ , equals  $\Delta U + P\Delta V$ . For the reaction given in the text,  $P\Delta V$  is essentially zero.

Symbol	Z	A	Mass (amu)	Symbol	Z	A	Mass (amu)

Cr	24	52	51.94051		92	238	238.05078
Fe	26	56	55.93494	Pu	94	239	239.05216

By contrast, the mass changes in nuclear reactions are approximately a million times larger per mole of reactant than those in chemical reactions. Consider the alpha decay of uranium-238 to thorium-234. The nuclear equation is

Here we have written the nuclear mass (in amu) beneath each nuclide symbol. (Table 20.3 lists masses of some elements and other particles.) The change in mass for this nuclear reaction, starting with molar amounts, is

$$\Delta m = (233.9942 + 4.00150 - 238.0003) \text{ g} = -0.0046 \text{ g}$$

As in calculating  $\Delta H$  and similar quantities, you subtract the value for the reactant from the sum of the values for the products. The minus sign indicates a loss of mass. This loss of mass is clearly large enough to detect.

From a table of atomic masses, such as Table 20.3, you can use Einstein's equation to calculate the energy change for a nuclear reaction. This is illustrated in the next example. Recall from Section 20.2 that  $1 \text{ eV} = 1.602 \times 10^{-19} \text{ J}$ . Therefore,  $1 \text{ MeV}$  equals  $1.602 \times 10^{-13} \text{ J}$ .

### Example 20.12 Calculating the Energy Change for a Nuclear Reaction

#### Gaining Mastery Toolbox

##### Critical Concept 20.12

All types of reactions, both chemical and nuclear, undergo a mass change ( $\Delta m$ ) when going from reactants to products. The change in mass is related to a change in energy by the equation  $\Delta E = (\Delta m)c^2$ ; a reduction in mass leads

- a. Calculate the energy change in joules (four significant figures) for the following nuclear reaction per mole of  ${}^1_1\text{H}$ :

Atomic and particle masses are given in Table 20.3; the speed of light is given on the inside back cover of this book.

- b. What is the energy change in MeV for one  ${}^1_1\text{H}$  nucleus?

(continued)

**Example 20.12** (continued)

to the production of energy. Nuclear reactions undergo a relatively significant reduction in mass when going from reactants to products, thereby producing great amounts of energy. Ordinary chemical reactions do not undergo significant mass changes so that they produce far less energy than nuclear reactions.

**Solution Essentials:**

- Einstein's equation ( $\Delta E = (\Delta m)c^2$ )
- Nuclear mass
- Electron volt
- Metric prefixes

**Problem Strategy** In order to calculate the energy changes for both parts of this problem, we will need to use Einstein's equation in the form  $\Delta E = (\Delta m)c^2$ . When using this equation for this type of calculation, we will use the nuclear mass of the nuclides. For part a, we will need to determine the mass change ( $\Delta m$ ) of the given nuclear reaction per mole of  ${}^2_1\text{H}$ . For part b, we calculate  $\Delta m$  for one  ${}^2_1\text{H}$  nucleus. Finally, we convert our answer from joules to MeV.

**Solution**

a. You need to write the *nuclear* masses below each nuclide symbol and then calculate  $\Delta m$ . Once you have  $\Delta m$ , you can obtain  $\Delta E$ . The nuclear mass of a nuclide is the mass of the atom minus the mass of the electrons. For example, using mass information from Table 20.3, you calculate the nuclear mass of  ${}^4_2\text{He}$  by starting with the atomic mass of  ${}^4_2\text{He}$  and subtracting the mass of two electrons.

$$\text{Nuclear mass of } {}^4_2\text{He} = 4.00260 \text{ amu} - (2 \times 0.000549 \text{ amu}) = 4.001502 \text{ amu}$$

Hence,

$$\begin{aligned} \Delta m &= (4.00150 + 1.00728 - 2.01345 - 3.01493) \text{ amu} \\ &= -0.01960 \text{ amu} \end{aligned}$$

To obtain the energy change for molar amounts, note that the molar mass of an atom in grams is numerically equal to the mass of a single atom in amu. Therefore, the mass change for molar amounts in this nuclear reaction is  $-0.01960 \text{ g}$ , or  $-1.960 \times 10^{-5} \text{ kg}$ . The energy change is

$$\begin{aligned} \Delta E &= (\Delta m)c^2 = (-1.960 \times 10^{-5} \text{ kg})(2.998 \times 10^8 \text{ m/s})^2 \\ &= -1.762 \times 10^{12} \text{ kg}\cdot\text{m}^2/\text{s}^2 \quad \text{or} \quad -1.762 \times 10^{12} \text{ J} \end{aligned}$$

b. The mass change for the reaction of one  ${}^2_1\text{H}$  atom is  $-0.01960 \text{ amu}$ . First change this to grams. Recall that 1 amu equals 1/12 the mass of a  ${}^{12}_6\text{C}$  atom, whose mass is  $12 \text{ g}/6.022 \times 10^{23}$ . Thus,  $1 \text{ amu} = 1 \text{ g}/6.022 \times 10^{23}$ . Hence, the mass change in grams is

$$\begin{aligned} \Delta m &= -0.01960 \text{ amu} \times \frac{1 \text{ g}}{1 \text{ amu} \times 6.022 \times 10^{23}} \\ &= -3.255 \times 10^{-26} \text{ g} \quad (\text{or } -3.255 \times 10^{-29} \text{ kg}) \end{aligned}$$

Then,

$$\begin{aligned} \Delta E &= (\Delta m)c^2 = (-3.255 \times 10^{-29} \text{ kg})(2.998 \times 10^8 \text{ m/s})^2 \\ &= -2.926 \times 10^{-12} \text{ J} \end{aligned}$$

Now convert this to MeV:

$$\Delta E = -2.926 \times 10^{-12} \text{ J} \times \frac{1 \text{ MeV}}{1.602 \times 10^{-13} \text{ J}} = -18.26 \text{ MeV}$$

**Answer Check** When calculating mass changes for nuclear reactions, you should expect answers in the small magnitude shown in this example ( $10^{-26} \text{ g}$ ). Any mass change significantly larger than this value should be suspect.

**Exercise 20.12** a. Calculate the energy change in joules when 1.00 g  ${}^{234}_{90}\text{Th}$  decays to  ${}^{234}_{91}\text{Pa}$  by beta emission. See Problems 20.81 and 20.82.  
b. What is the energy change in MeV when one  ${}^{234}_{90}\text{Th}$  nucleus decays? Use Table 20.3 for these calculations.

## Nuclear Binding Energy

The equivalence of mass and energy explains the otherwise puzzling fact that the mass of an atom is always less than the sum of the masses of its constituent particles. For example, the helium-4 atom consists of two protons, two neutrons, and two electrons, giving the following sum:

$$\begin{aligned} \text{Mass of 2 electrons} &= 2 \times 0.000549 \text{ amu} = 0.00110 \text{ amu} \\ \text{Mass of 2 protons} &= 2 \times 1.00728 \text{ amu} = 2.01456 \text{ amu} \\ \text{Mass of 2 neutrons} &= 2 \times 1.00867 \text{ amu} = 2.01734 \text{ amu} \\ \text{Total mass of particles} &= 4.03300 \text{ amu} \end{aligned}$$

The mass of the helium-4 atom is 4.00260 amu (see Table 20.3), so the mass difference is

$$\Delta m = (4.00260 - 4.03300) \text{ amu} = -0.03040 \text{ amu}$$

This mass difference is explained as follows. When the nucleons come together to form a nucleus, energy is released. (The nucleus has lower energy and is therefore more stable than the separate nucleons.) According to Einstein's equation, there must be an equivalent decrease in mass.

The **binding energy** of a nucleus is *the energy needed to break a nucleus into its individual protons and neutrons*. Thus, the binding energy of the helium-4 nucleus is the energy change for the reaction

The **mass defect** of a nucleus is *the nucleon mass minus the atomic mass*. In the case of helium-4, the mass defect is 4.03300 amu – 4.00260 amu = 0.03040 amu. (This is the positive value of the mass difference we calculated earlier.) Both the binding energy and the corresponding mass defect are reflections of the stability of the nucleus.

To compare the stabilities of various nuclei, it is useful to compare binding energies per nucleon. Figure 20.18 shows values of this quantity (in MeV per nucleon) plotted against the mass number for various nuclides. Most of the points lie near the smooth curve drawn on the graph.

Note that nuclides near mass number 50 have the largest binding energies per nucleon. This means that a group of nucleons would tend to form those nuclides, because they would form nuclei of the lowest energy. For this reason, heavy nuclei might be expected to split to give lighter nuclei, and light nuclei might be expected to react, or combine, to form heavier nuclei.

**Figure 20.18** ◀

**Plot of binding energy per nucleon versus mass number** The binding energy of each nuclide is divided by the number of nucleons (total of protons and neutrons), then plotted against the mass number of the nuclide. Note that nuclides near mass number 50 have the largest binding energies per nucleon. Thus, heavy nuclei are expected to undergo fission to approach this mass number, whereas light nuclei are expected to undergo fusion.

**Nuclear fission** is a nuclear reaction in which a heavy nucleus splits into lighter nuclei and energy is released. For example, californium-252 decays both by alpha emission (97%) and by spontaneous fission (3%). There are many possible ways in which the nucleus can split. One way is represented by the following equation:

In some cases, a nucleus can be induced to undergo fission by bombarding it with neutrons. An example is the nuclear fission of uranium-235. When a neutron strikes the  ${}_{92}^{235}\text{U}$  nucleus, the nucleus splits into roughly equal parts, giving off several neutrons. Three possible splittings are shown in the following equations:

Nuclear fission is discussed further in Section 20.7.

**Nuclear fusion** is a nuclear reaction in which light nuclei combine to give a more stable, heavier nucleus plus possibly several neutrons, and energy is released. An example of nuclear fusion is

Even though a nuclear reaction is energetically favorable, the reaction may be imperceptibly slow unless the proper conditions are present (see Section 20.7).

## 20.7 Nuclear Fission and Nuclear Fusion

We have seen that the stablest nuclei are those of intermediate size (with mass numbers around 50). Nuclear fission and nuclear fusion are reactions in which nuclei attain sizes closer to this intermediate range. In doing so, these reactions release tremendous amounts of energy. Nuclear fission of uranium-235 is employed in nuclear power plants to generate electricity. Nuclear fusion may supply us with energy in the future.

### Nuclear Fission; Nuclear Reactors

Nuclear fission was discovered as a result of experiments to produce transuranium elements. Soon after the neutron was discovered in 1932, experimenters realized that this particle, being electrically neutral, should easily penetrate heavy nuclei. They began using neutrons in bombardment reactions, hoping to produce isotopes that would decay to new elements. In 1938, Otto Hahn, Lise Meitner, and Fritz Strassmann in Berlin identified barium in uranium samples that had been bombarded with neutrons. Soon afterward, the presence of barium was explained as a result of fission of the uranium-235 nucleus. When this nucleus is struck by a neutron, it splits into two nuclei. Fissions of uranium nuclei produce approximately 30 different elements of intermediate mass, including barium.

When the uranium-235 nucleus splits, approximately two or three neutrons are released. If the neutrons from each nuclear fission are absorbed by other uranium-235 nuclei, these nuclei split and release even more neutrons. In this way, a chain reaction can occur. A nuclear **chain reaction** is a self-sustaining series of nuclear fissions caused by the absorption of neutrons released from previous nuclear fissions. The numbers of nuclei that split quickly multiply as a result of the absorption of neutrons released from previous nuclear fissions. Figure 20.19 shows how such a chain reaction occurs. The chain reaction of nuclear fissions is the basis of nuclear power and nuclear weapons.

Figure 20.19 ◀

**Representation of a chain reaction of nuclear fissions** Each nuclear fission produces two or more neutrons, which can in turn cause more nuclear fissions. At each stage, a greater number of neutrons are produced, so the number of nuclear fissions multiplies quickly. Such a chain reaction is the basis of nuclear power and nuclear weapons. The original nucleus splits into pieces of varying mass number.

To sustain a chain reaction in a sample of fissionable material, a nucleus that splits must give an average of one neutron that results in the fission of another nucleus, and so on. If the sample is too small, many of the neutrons leave the sample before they have a chance to be absorbed. There is thus a **critical mass** for a particular fissionable material, which is *the smallest mass of fissionable material in which a chain reaction can be sustained*. If the mass is much larger than this (a *supercritical mass*), the numbers of nuclei that split multiply rapidly. An atomic bomb is detonated with a small amount of chemical explosive that pushes together two or more masses of fissionable material to get a supercritical mass (Figure 20.20). A rapid chain reaction results in the splitting of most of the fissionable nuclei—and in the explosive release of an enormous amount of energy.

A **nuclear fission reactor** is a device that permits a controlled chain reaction of nuclear fissions. In power plants, a nuclear reactor is used to produce heat, which in turn is used to produce steam to drive an electric generator. A nuclear reactor consists of fuel rods alternating with control rods contained within a vessel. The **fuel rods** are the cylinders that contain fissionable material. In the light-water (ordinary water) reactors commonly used in the United States (see Figure 20.21), these fuel rods contain uranium dioxide pellets in a zirconium alloy tube. Natural uranium contains only 0.72% uranium-235, which is the isotope that undergoes fission. The uranium used for fuel in these reactors is “enriched” so that it contains about 3% of the uranium-235 isotope. **Control rods** are cylinders composed of substances that absorb neutrons, such as boron and cadmium, and can therefore slow the chain reaction. By varying the depth of the control rods within the fuel-rod assembly (reactor core), one can increase or decrease the absorption of neutrons. If necessary, these rods can be dropped all the way into the fuel-rod assembly to stop the chain reaction.

A **moderator**, a substance that slows down neutrons, is required if uranium-235 is the fuel and this isotope is present as a small fraction of the total fuel. The neutrons that are released by the splitting of uranium-235 nuclei are absorbed more readily by uranium-238 than by other uranium-235 nuclei. However, when the neutrons are slowed down by a moderator, they are more readily absorbed by

Figure 20.20 ▲

**An atomic bomb** In the gun-type bomb, one piece of uranium-235 of subcritical mass is hurled into another piece by a chemical explosive. The two pieces together give a supercritical mass, and a nuclear explosion results. Bombs using plutonium-239 require an implosion technique, in which wedges of plutonium arranged on a spherical surface are pushed into the center of the sphere by a chemical explosive, where a supercritical mass of plutonium results in a nuclear explosion.

**Figure 20.21** ▲

**Light-water nuclear reactor** The nuclear reactor consists of fuel rods with interspersed control rods. By raising or lowering the control rods, an operator can increase or decrease the rate of energy release from the fuel rods. Heat from the fuel rods raises the temperature of the liquid water in the reactor. A pump circulates the hot water to a steam generator, and the resulting steam passes through a turbine that operates an electric generator. The steam leaves the turbine and goes into the condenser, where it liquefies on the cooling coil. A nearby river or lake provides the cold water for the condenser.

uranium-235, so it is possible to sustain a chain reaction with low fractional abundance of this isotope. Commonly used moderators are heavy water ( ${}^2\text{H}_2\text{O}$ ), light water, and graphite.

In the light-water reactor, ordinary water acts as both a moderator and a coolant. Figure 20.21 shows a pressurized-water design of this type of reactor. Water in the reactor is maintained at about  $350^\circ\text{C}$  under high pressure (150 atm) so it does not boil. The hot water is circulated to a heat exchanger, where the heat is used to produce steam to run a turbine and generate electricity.

After a period of time, fission products that absorb neutrons accumulate in the fuel rods. This interferes with the chain reaction, so eventually the fuel rods must be replaced. Originally, the intention was to send these fuel rods to *reprocessing plants*, where fuel material could be chemically separated from the radioactive wastes. Opposition to constructing these plants has been intense, however. Plutonium-239 would be one of the fuel materials separated from the spent fuel rods. This isotope is produced during the operation of the reactor when uranium-238 is bombarded with neutrons. It is fissionable and can be used to construct atomic bombs. For this reason, many people believe that the availability of this element in large quantities would increase the chance that many countries and terrorist groups could divert enough plutonium to produce atomic bombs.

Whether or not the spent fuel rods are reprocessed, a pressing problem facing the nuclear power industry is how to dispose of radioactive wastes safely. One of many proposals is to encase the waste in a ceramic material and store the solids deep in the earth, perhaps in salt mines.

## Nuclear Fusion

As we noted in Section 20.6, energy can be obtained by combining light nuclei into a heavier nucleus by nuclear fusion. Such fusion reactions have been observed in the laboratory by means of bombardment using particle accelerators. Deuterons ( ${}^2_1\text{H}$  nuclei), for example, can be accelerated toward targets containing deuterium ( ${}^2_1\text{H}$  atoms) or tritium ( ${}^3_1\text{H}$  atoms). The reactions are

To get the nuclei to react, the bombarding nucleus must have enough kinetic energy to overcome the repulsion of electric charges of the nuclei. The first reaction uses only deuterium, which is present in ordinary water. ► It is therefore very attractive as a source of energy. But, as we will discuss, the second reaction is more likely to be used first.

Energy cannot be obtained in a practical way using particle accelerators. Another way to give nuclei sufficient kinetic energy to react is by heating the nuclear materials to a sufficiently high temperature. The reaction of deuterium,  ${}^2_1\text{H}$ , and tritium,  ${}^3_1\text{H}$ , turns out to require the lowest temperature of any fusion reaction. For this reason, it is likely to be the first fusion reaction developed as an energy source. For practical purposes, the temperature will have to be about 100 million °C. At this temperature, all atoms have been stripped of their electrons, so a plasma results. A **plasma** is an electrically neutral gas of ions and electrons. At 100 million °C, the plasma is essentially separate nuclei and electrons. Thus, the development of nuclear fusion requires study of the properties of plasmas at high temperatures.

It is now believed that the energy of stars, including our sun, where extremely high temperatures exist, derives from nuclear fusion. The hydrogen bomb also employs nuclear fusion for its destructive power. High temperature is first attained by a fission bomb. This then ignites fusion reactions in surrounding material of deuterium and tritium.

The main problem in developing controlled nuclear fusion is how to heat a plasma to high temperature and maintain those temperatures. When a plasma touches any material whatsoever, heat is quickly conducted away, and the plasma temperature quickly falls. ► A *magnetic fusion reactor* uses a magnetic field to hold the plasma away from any material (see Figure 20.22). A *laser fusion reactor* employs a bank of lasers aimed at a single point. Pellets containing deuterium and tritium would drop into the reactor, where they would be heated to 100 million °C by bursts of laser light.

Figure 20.22 ▲

**Torus Fusion Reactor** The National Spherical Torus Experiment at the Princeton Plasma Physics Laboratory uses this reactor to test an advanced magnetic field configuration to confine a compact, spherically shaped plasma.

Natural hydrogen contains 0.015% deuterium.

Even though the plasma is nearly 100 million °C above the melting point of any material, the total quantity of heat that could be transferred from the plasma is very small, because its concentration is extremely low. Therefore, if the plasma were to touch the walls of the reactor, the plasma would cool but the walls would not melt.

## ✓ A Checklist for Review

### Summary of Facts and Concepts

Nuclear reactions are of two types, *radioactive decay* and *nuclear bombardment*. Such reactions are represented by nuclear equations, each nucleus being denoted by a nuclide symbol. The equations must be balanced in charge (subscripts) and in nucleons (superscripts).

According to the *nuclear shell model*, the nucleons are arranged in shells. *Magic numbers* are the numbers

of nucleons in a completed shell of protons or neutrons. Nuclei with magic numbers of protons or neutrons are especially stable. Pairs of protons and pairs of neutrons are also especially stable. When placed on a plot of  $N$  versus  $Z$ , stable nuclei fall in a *band of stability*. Those radioactive nuclides that fall to the left of the band of stability in this plot usually decay by beta emission. Those radioactive nuclides

that fall to the right of the band of stability usually decay by positron emission or electron capture. However, nuclides with  $Z > 83$  often decay by alpha emission. Uranium-238 forms a *radioactive decay series*. In such series, one element decays to another, which decays to another, and so forth, until a stable isotope is reached (lead-206, in the case of the uranium-238 series).

*Transmutation* of elements has been carried out in the laboratory by bombarding nuclei with various atomic particles. Alpha particles from natural sources can be used as reactants with light nuclei. For heavier nuclei, positive ions such as alpha particles must first be accelerated in a *particle accelerator*. Many of the *transuranium elements* have been obtained by bombardment of elements with accelerated particles. For example, plutonium was first made by bombarding uranium-238 with deuterons ( ${}^2_1\text{H}$  nuclei) from a *cyclotron*, a type of particle accelerator.

Particles of radiation from nuclear processes can be counted by Geiger counters or scintillation counters. In a *Geiger counter*, the particle ionizes a gas, which then conducts a pulse of electricity between two electrodes. In a *scintillation counter*, the particle hits a phosphor, and this emits a flash of light that is detected by a photomultiplier tube. The activity of a radioactive source, or the number of nuclear disintegrations per unit time, is measured in units of *curies* ( $3.700 \times 10^{10}$  disintegrations per second).

Radiation affects biological organisms by breaking chemical bonds. The *rad* is the measure of radiation dosage that deposits  $1 \times 10^{-2}$  J of energy per kilogram of tissue.

A *rem* equals the number of rads times a factor to account for the relative biological effectiveness of the radiation.

Radioactive decay is a first-order rate process. The rate is characterized by the *decay constant*,  $k$ , or by the *half-life*,  $t_{1/2}$ . The quantities  $k$  and  $t_{1/2}$  are related. Knowing one or the other, you can calculate how long it will take for a given radioactive sample to decay by a certain fraction. Methods of *radioactive dating* depend on determining the fraction of a radioactive isotope that has decayed and, from this, the time that has elapsed.

Radioactive isotopes are used as *radioactive tracers* in chemical analysis and medicine. *Isotope dilution* is one application of radioactive tracers in which the dilution of the tracer can be related to the original quantity of nonradioactive isotope. *Neutron activation analysis* is a method of analysis that depends on the conversion of elements to radioactive isotopes by neutron bombardment.

According to Einstein's *mass-energy equivalence*, mass is related to energy by the equation  $E = mc^2$ . A nucleus has less mass than the sum of the masses of the separate nucleons. The positive value of this mass difference is called the *mass defect*; it is equivalent to the *binding energy* of the nucleus. Nuclides having mass numbers near 50 have the largest binding energies per nucleon. It follows that heavy nuclei should tend to split, a process called *nuclear fission*, and that light nuclei should tend to combine, a process called *nuclear fusion*. Tremendous amounts of energy are released in both processes. Nuclear fission is used in conventional nuclear power reactors. Nuclear fusion reactors are in the experimental stage.

## Learning Objectives

### 20.1 Radioactivity

- Define *radioactive decay* and *nuclear bombardment reaction*.
- Learn the nuclear symbols for *positron*, *gamma photon*, *electron*, *neutron*, and *proton*.
- Write a nuclear equation. **Example 20.1**
- Deduce a product or reactant in a nuclear equation. **Example 20.2**
- Describe the *shell model of the nucleus*.
- Explain the *band of stability*.
- Predict the relative stabilities of nuclides. **Example 20.3**
- List the six types of radioactive decay.
- Predict the type of radioactive decay. **Example 20.4**
- Define *radioactive decay series*.

## Important Terms

radioactive decay  
 nuclear bombardment reaction  
 nuclear equation  
 positron  
 gamma photon  
 nuclear force  
 shell model of the nucleus  
 magic number  
 band of stability  
 alpha emission  
 beta emission  
 positron emission  
 electron capture  
 gamma emission  
 metastable nucleus  
 spontaneous fission  
 radioactive decay series

### 20.2 Nuclear Bombardment Reactions

- Define *transmutation*.
- Use the notation for a bombardment reaction. **Example 20.5**
- Locate the *transuranium elements* on the periodic table.
- Determine the product nucleus in a nuclear bombardment reaction. **Example 20.6**

transmutation  
 particle accelerator  
 electron volt (eV)  
 cyclotron  
 deuterons  
 transuranium elements

## Questions and Problems

### Self-Assessment and Review Questions

**Key:** These questions test your understanding of the ideas you worked with in the chapter. These problems vary in difficulty and often can be used for the basis of discussion.

**20.1** What are the two types of nuclear reactions? Give an example of a nuclear equation for each type.

**20.2** What are *magic numbers*? Give several examples of nuclei with magic numbers of protons.

**20.3** List characteristics to look for in a nucleus to predict whether it is stable.

**20.4** What are the six common types of radioactive decay? What condition usually leads to each type of decay?

**20.5** What are the isotopes that begin each of the naturally occurring radioactive decay series?

**20.6** Give equations for **a** the first transmutation of an element obtained in the laboratory by nuclear bombardment, and for **b** the reaction that produced the first artificial radioactive isotope.

**20.7** What is a particle accelerator, and how does one operate? Why are they required for certain nuclear reactions?

**20.8** In what major way has the discovery of transuranium elements affected the form of modern periodic tables?

**20.9** Describe how a Geiger counter works. How does a scintillation counter work?

**20.10** Define the units *curie*, *rad*, and *rem*.

**20.11** The half-life of cesium-137 is 30.2 y. How long will it take for a sample of cesium-137 to decay to 1/8 of its original mass?

**20.12** What is the age of a rock that contains equal numbers of  $^{40}_{19}\text{K}$  and  $^{40}_{18}\text{Ar}$  nuclei? The half-life of  $^{40}_{19}\text{K}$  is  $1.28 \times 10^9$  y.

**20.13** What is a radioactive tracer? Give an example of the use of such a tracer in chemistry.

**20.14** Isotope dilution has been used to obtain the volume of blood supply in a living animal. Explain how this could be done.

**20.15** Briefly describe neutron activation analysis.

**20.16** The deuteron,  $^2_1\text{H}$ , has a mass that is smaller than the sum of the masses of its constituents, the proton plus the neutron. Explain why this is so.

**20.17** Certain stars obtain their energy from nuclear reactions such as

Explain in a sentence or two why this reaction might be expected to release energy.

**20.18** Briefly describe how a nuclear fission reactor operates.

**20.19** Polonium-216 decays to lead-212 by emission of an alpha particle. Which of the following is the nuclear equation for this radioactive decay?

**20.20** The half-life for the decay of carbon-14 is 5730 years. Present-day carbon (in living matter) gives 15.3 disintegrations of  $^{14}\text{C}$  per minute per gram of total carbon. An archaeological sample containing carbon was dated by analysis of its radioactive carbon. The activity of the carbon from the sample was 5.4 disintegrations of  $^{14}\text{C}$  per minute per gram of total carbon. What was the age of the sample?

**a**  $2.4 \times 10^{-5}$  y

**b**  $1.2 \times 10^4$  y

**c**  $3.7 \times 10^3$  y

**d**  $7.2 \times 10^3$  y

**e**  $8.6 \times 10^3$  y

**20.21** A radioactive isotope has a half-life of 56.6 days. What fraction of the isotope remains after 449 days?

**a**  $3.2 \times 10^{-6}$

**b** 1.00

**c** 0.92

**d**  $4.1 \times 10^{-3}$

**e** 0.83

**20.22** Neutron activation analysis is an analytical technique in which a sample of material is bombarded with neutrons from a fission reactor. When a 35.0-g aluminum can is irradiated, it has an initial activity of 40.0 curies (Ci). The safety office won't let you touch anything having an activity in excess of 0.100 Ci. Assuming all the radioactivity is from  $^{28}\text{Al}$ , which has a half-life of 2.28 min, how many minutes do you have to wait after bombardment before you can handle the can safely?

**a** 17.0 min

**b**  $1.32 \times 10^3$  min

**c** 19.7 min

**d** 478 min

**e** 476 min

### Conceptual Problems

**Key:** These problems are designed to check your understanding of the concepts associated with some of the main topics presented in each chapter. A strong conceptual understanding of chemistry is the foundation for both applying chemical knowledge and solving chemical problems. These problems vary in level of difficulty and often can be used as a basis for group discussion.

**20.23** When considering the lifetime of a radioactive species, a general rule of thumb is that after 10 half-lives have passed, the amount of radioactive material left in the sample is negligible. The disposal of some radioactive materials is based on this rule.

**a** What percentage of the original material is left after 10 half-lives?

**b** When would it be a bad idea to apply this rule?

**20.24** Use drawings to complete the following nuclear reactions (yellow circles represent neutrons and blue circles represent protons). Once you have completed the drawings, write the nuclide symbols under each reaction.

**20.25** Sodium has only one naturally occurring isotope, sodium-23. Using the data presented in Table 20.3, explain how the molecular weight of sodium is 22.98976 amu and not the sum of the masses of the protons, neutrons, and electrons.

**20.26** Identify each of the following reactions as fission, fusion, a transmutation, or radioactive decay.

- a  $4\text{}^1_1\text{H} \longrightarrow \text{}^4_2\text{He} + 2\text{}^0_{-1}\text{e}$   
 b  $^{14}_6\text{C} \longrightarrow \text{}^{14}_7\text{N} + \text{}^0_{-1}\text{e}$   
 c  $^1_0\text{n} + \text{}^{235}_{92}\text{U} \longrightarrow \text{}^{140}_{56}\text{Ba} + \text{}^{93}_{36}\text{Kr} + 3\text{}^0_{-1}\text{e}$   
 d  $^{14}_7\text{N} + \text{}^4_2\text{He} \longrightarrow \text{}^{17}_8\text{O} + \text{}^1_1\text{H}$

**20.27** A radioactive sample with a half-life of 10 minutes is placed in a container.

- a Complete the pictures below depicting the amount of this sample at the beginning of the experiment ( $t = 0$  min) and 30 minutes into the experiment ( $t = 30$  min). Each sphere represents one radioactive nuclide of the sample.

- b A friend working with 1000 atoms of the same nuclide represents the amount of nuclide at three time intervals in the following manner.

Is his drawing correct? If not, explain where and why it is incorrect.

**20.28** You have a mixture that contains 10 g of Pu-239 with a half-life of  $2.4 \times 10^4$  years and 10 g of Np-239 with a half-life of 2.4 days. Estimate how much time must elapse before the quantity of radioactive material is reduced by 50%.

**20.29** Come up with an explanation as to why  $\alpha$  radiation is easily blocked by materials such as a piece of wood, whereas  $\gamma$  radiation easily passes through those same materials.

**20.30** You have an acquaintance who tells you that he is going to reduce his radiation exposure to zero. What examples could you present that would illustrate this to be an impossible goal?

**20.31** Gamma radiation can be used to kill bacteria in food using a process called irradiation. There is concern on the part of some people that the irradiated food is radioactive. Why is this not the case? If you wanted to make the food radioactive, what would you have to do?

**20.32** You have a pile of I-131 atoms with a half-life of 8 days. A portion of the solid I-131 is represented below. Can you predict how many half-lives will occur before the green I-131 atom undergoes decay?

## Practice Problems

**Key:** These problems are for practice in applying problem-solving skills. They are divided by topic, and some are keyed to exercises (see the ends of the exercises). The problems are arranged in matching pairs; the odd-numbered problem of each pair is listed first, and its answer is given in the back of the book.

### Radioactivity

**20.33** Rubidium-87, which forms about 28% of natural rubidium, is radioactive, decaying by the emission of a single beta particle to strontium-87. Write the nuclear equation for this decay of rubidium-87.

**20.34** Write the nuclear equation for the decay of phosphorus-32 to sulfur-32 by beta emission. A phosphorus-32 nucleus emits a beta particle and gives a sulfur-32 nucleus.

**20.35** Thorium is a naturally occurring radioactive element. Thorium-232 decays by emitting a single alpha particle to produce radium-228. Write the nuclear equation for this decay of thorium-232.

**20.36** Radium is a radioactive noble gas formed in soil containing radium. Radium-226 decays by emitting a single alpha particle to produce radon-222. Write the nuclear equation for this decay of radium-226.

**20.37** Fluorine-18 is an artificially produced radioactive isotope. It decays by emitting a single positron. Write the nuclear equation for this decay.

**20.38** Scandium-41 is an artificially produced radioactive isotope. It decays by emitting a single positron. Write the nuclear equation for this decay.

## 719c

## Nuclear Chemistry

**20.39** Polonium was discovered in uranium ores by Marie and Pierre Curie. Polonium-210 decays by emitting a single alpha particle. Write the nuclear equation for this decay.

**20.40** Actinium was discovered in uranium ore residues by André-Louis Debierne. Actinium-227 decays by emitting a single alpha particle. Write the nuclear equation for this decay.

**20.41** From each of the following pairs, choose the nuclide that is radioactive. (One is known to be radioactive, the other stable.) Explain your choice.

**20.42** From each of the following pairs, choose the nuclide that is radioactive. (One is known to be radioactive, the other stable.) Explain your choice.

**20.43** Predict the type of radioactive decay process that is likely for each of the following nuclides.

**20.44** Predict the type of radioactive decay process that is likely for each of the following nuclides.

**20.45** Four radioactive decay series are known—three naturally occurring, and one beginning with the synthetic isotope  ${}_{94}^{241}\text{Pu}$ . To which of these decay series does the isotope  ${}_{86}^{218}\text{Rn}$  belong? To which series does  ${}_{86}^{220}\text{Rn}$  belong? Each isotope in these series decays by either alpha emission or beta emission. How do these decay processes affect the mass number?

**20.46** Four radioactive decay series are known—three naturally occurring, and one beginning with the synthetic isotope  ${}_{94}^{241}\text{Pu}$ . To which of these decay series does the isotope  ${}_{89}^{227}\text{Ac}$  belong? To which series does  ${}_{89}^{225}\text{Ac}$  belong? Each isotope in these series decays by either alpha emission or beta emission. How do these decay processes affect the mass number?

### Nuclear Bombardment Reactions

**20.47** Write the abbreviated notations for the following bombardment reactions.

**20.48** Write abbreviated notations for the following bombardment reactions.

**20.49** Write the nuclear equations for the following bombardment reactions.

**20.50** Write the nuclear equations for the following bombardment reactions.

**20.51** A proton is accelerated to 12.6 MeV per particle. What is this energy in kJ/mol?

**20.52** An alpha particle is accelerated to 23.1 MeV per particle. What is this energy in kJ/mol?

**20.53** Fill in the missing parts of the following reactions.

**20.54** Fill in the missing parts of the following reactions.

**20.55** Curium was first synthesized by bombarding an element with alpha particles. The products were curium-242 and a neutron. What was the target element?

**20.56** Californium was first synthesized by bombarding an element with alpha particles. The products were californium-245 and a neutron. What was the target element?

### Rate of Radioactive Decay

**20.57** Tritium, or hydrogen-3, is prepared by bombarding lithium-6 with neutrons. A 0.250-mg sample of tritium decays at the rate of  $8.94 \times 10^{10}$  disintegrations per second. What is the decay constant (in /s) of tritium, whose atomic mass is 3.02 amu?

**20.58** The first isotope of plutonium discovered was plutonium-238. It is used to power batteries for heart pacemakers. A sample of plutonium-238 weighing  $2.8 \times 10^{-6}$  g decays at the rate of  $1.8 \times 10^6$  disintegrations per second. What is the decay constant of plutonium-238 in reciprocal seconds (/s)?

**20.59** A  $4.00 \times 10^{-2}$ -mol sample of a radioisotope has an activity of 56.5 Ci. What is the decay constant of the isotope (in /s)?

**20.60** Sodium-24 is used in medicine to study the circulatory system. A sample weighing  $5.2 \times 10^{-6}$  g has an activity of 45.3 Ci. What is the decay constant of sodium-24 (in /s)?

**20.61** Tellurium-123 is a radioactive isotope occurring in natural tellurium. The decay constant is  $1.7 \times 10^{-21}$ /s. What is the half-life in years?

**20.62** Neptunium-237 was the first isotope of a transuranium element to be discovered. The decay constant is  $1.03 \times 10^{-14}$ /s. What is the half-life in years?

**20.63** Carbon-14 has been used to study the mechanisms of reactions that involve organic compounds. The half-life of carbon-14 is  $5.73 \times 10^3$  y. What is the decay constant (in /s)?

**20.64** Promethium-147 has been used in luminous paint for dials. The half-life of this isotope is 2.5 y. What is the decay constant (in /s)?

**20.65** Gold-198 has a half-life of 2.69 d. What is the activity (in curies) of a 0.92-mg sample?

**20.66** Cesium-134 has a half-life of 2.05 y. What is the activity (in curies) of a 0.50-mg sample?

**20.67** A sample of a phosphorus compound contains phosphorus-32. This sample of radioactive isotope is decaying at the rate of  $6.3 \times 10^{12}$  disintegrations per second. How many grams of  ${}^{32}\text{P}$  are in the sample? The half-life of  ${}^{32}\text{P}$  is 14.3 d.

**20.68** A sample of sodium thiosulfate,  $\text{Na}_2\text{S}_2\text{O}_3$ , contains sulfur-35. Determine the mass of  ${}^{35}\text{S}$  in the sample from the decay rate, which was determined to be  $7.3 \times 10^{11}$  disintegrations per second. The half-life of  ${}^{35}\text{S}$  is 88 d.

**20.69** A sample of sodium-24 was administered to a patient to test for faulty blood circulation by comparing the

radioactivity reaching various parts of the body. What fraction of the sodium-24 nuclei would remain undecayed after 12.0 h? The half-life is 15.0 h. If a sample contains 6.0  $\mu\text{g}$  of  $^{24}\text{Na}$ , how many micrograms remain after 12.0 h?

**20.70** A solution of sodium iodide containing iodine-131 was given to a patient to test for malfunctioning of the thyroid gland. What fraction of the iodine-131 nuclei would remain undecayed after 5.0 d? If a sample contains 2.5  $\mu\text{g}$  of  $^{131}\text{I}$ , how many micrograms remain after 5.0 d? The half-life of I-131 is 8.07 d.

**20.71** If 24.0% of a sample of radioisotope decays in 8.73 s, what is the half-life of this isotope (in seconds)?

**20.72** If 20.0% of a sample of zinc-65 decays in 69.9 d, what is the half-life of this isotope (in days)?

**20.73** A sample of iron-59 initially registers 165 counts per second on a radiation counter. After 11.0 d, the sample registers 139 counts per second. What is the half-life (in days) of iron-59?

**20.74** A sample of silver-112 gives a reading of 875 counts per hour on a radiation counter. After 0.25 h, the sample gives a reading of 400 counts per hour. What is the half-life (in hours) of silver-112?

**20.75** Carbon from a cypress beam obtained from the tomb of Sneferu, a king of ancient Egypt, gave 8.8 disintegrations of  $^{14}\text{C}$  per minute per gram of carbon. How old is the cypress beam? Carbon from living material gives 15.3 disintegrations of  $^{14}\text{C}$  per minute per gram of carbon.

**20.76** Carbon from the Dead Sea Scrolls, very old manuscripts found in Israel, gave 12.1 disintegrations of  $^{14}\text{C}$  per minute per gram of carbon. How old are the manuscripts? Carbon from living material gives 15.3 disintegrations of  $^{14}\text{C}$  per minute per gram of carbon.

**20.77** Several hundred pairs of sandals found in a cave in Oregon were found by carbon-14 dating to be  $9.0 \times 10^3$  years

old. What must have been the activity of the carbon-14 in the sandals in disintegrations per minute per gram? Assume the original activity was 15.3 disintegrations per minute per gram.

**20.78** Some mammoth bones found in Arizona were found by carbon-14 dating to be  $1.13 \times 10^4$  years old. What must have been the activity of the carbon-14 in the bones in disintegrations per minute per gram? Assume the original activity was 15.3 disintegrations per minute per gram.

### Mass-Energy Equivalence

**20.79** Find the change of mass (in grams) resulting from the release of heat when 1 mol C reacts with 1 mol  $\text{O}_2$ .

**20.80** Find the change of mass (in grams) resulting from the release of heat when 1 mol  $\text{SO}_2$  is formed from the elements.

**20.81** Calculate the energy change for the following nuclear reaction (in joules per mole of  $^1_1\text{H}$ ).

Give the energy change in MeV per  $^1_1\text{H}$  nucleus. See Table 20.3.

**20.82** Calculate the change in energy, in joules per mole of  $^1_1\text{H}$ , for the following nuclear reaction.

Give the energy change in MeV per  $^1_1\text{H}$  nucleus. See Table 20.3.

**20.83** Obtain the mass defect (in amu) and binding energy (in MeV) for the  $^6_3\text{Li}$  nucleus. What is the binding energy (in MeV) per nucleon? See Table 20.3.

**20.84** Obtain the mass defect (in amu) and binding energy (in MeV) for the  $^{58}_{28}\text{Ni}$  nucleus. What is the binding energy (in MeV) per nucleon? See Table 20.3.

## General Problems

**Key:** These problems provide more practice but are not divided by topic or keyed to exercises. Each section ends with essay questions, each of which is color added to refer to the *A Chemist Looks at Frontiers* (purple) or *A Chemist Looks at Life Science* (pink) chapter essay on which it is based. Odd-numbered problems and the even-numbered problems that follow are similar; answers to all odd-numbered problems except the essay questions are given in the back of the book.

**20.85** Sodium-23 is the only stable isotope of sodium. Predict how sodium-20 will decay and how sodium-26 will decay.

**20.86** Aluminum-27 is the only stable isotope of aluminum. Predict how aluminum-24 will decay and how aluminum-30 will decay.

**20.87** A uranium-235 nucleus decays by a series of alpha and beta emissions until it reaches lead-207. How many alpha emissions and how many beta emissions occur in this series of decays?

**20.88** A thorium-232 nucleus decays by a series of alpha and beta emissions until it reaches lead-208. How many alpha emissions and how many beta emissions occur in this series of decays?

**20.89** A bismuth-209 nucleus reacts with an alpha particle to produce an astatine nucleus and two neutrons. Write the complete nuclear equation for this reaction.

**20.90** A bismuth-209 nucleus reacts with a deuteron to produce a polonium nucleus and a neutron. Write the complete nuclear equation for this reaction.

**20.91** Complete the following equation by filling in the blank.

**20.92** Complete the following equation by filling in the blank.

**20.93** Tritium, or hydrogen-3, is formed in the upper atmosphere by cosmic rays, similar to the formation of carbon-14. Tritium has been used to determine the age of wines. A certain wine that has been aged in a bottle has a tritium content only 64% of that in a similar wine of the same mass that has just been bottled. How long has the aged wine been in the bottle? The half-life of tritium is 12.3 y.

**20.94** The naturally occurring isotope rubidium-87 decays by beta emission to strontium-87. This decay is the basis of

a method for determining the ages of rocks. A sample of rock contains  $102.1 \mu\text{g}$   $^{87}\text{Rb}$  and  $5.0 \mu\text{g}$   $^{87}\text{Sr}$ . What is the age of the rock? The half-life of rubidium-87 is  $4.8 \times 10^{10}$  y.

**20.95** When an antiproton and proton collide, they are annihilated and two gamma photons of equal energy are emitted. Calculate the wavelength corresponding to this gamma emission.

**20.96** When technetium-99m decays to technetium-99, a gamma photon corresponding to an energy of 0.143 MeV is emitted. What is the wavelength of this gamma emission? What is the difference in mass between Tc-99m and Tc-99?

**20.97** Calculate the energy released when 4.50 kg of uranium-235 undergoes the following fission process.

The masses of  ${}_{53}^{136}\text{I}$  and  ${}_{39}^{96}\text{Y}$  nuclei are 135.8401 amu and 95.8629 amu, respectively. Other masses are given in Table 20.3. Compare this energy with the heat released when 4.50 kg C(graphite) burns to  $\text{CO}_2(\text{g})$ .

**20.98** Calculate the energy released when 1.00 kg of hydrogen-1 undergoes fusion to helium-4, according to the following reaction.

This reaction is one of the principal sources of energy from the sun. Compare the energy released by 1.00 kg of  ${}_1^1\text{H}$  in this reaction to the heat released when 1.00 kg of C(graphite) burns to  $\text{CO}_2(\text{g})$ . See Table 20.3 for data.

**20.99** The half-life of calcium-47 is 4.536 days and it decays by the emission of a beta particle.

**a** Write a balanced equation for the decay of Ca-47.

**b** If  $10.0 \mu\text{g}$  of Ca-47 is needed for an experiment, what mass of  ${}^{47}\text{CaSO}_4$  must be ordered if it takes 48 h for it to arrive from the supplier?

**20.100** The radioactive isotope phosphorus-32 is often used in biochemical research. Its half-life is 14.28 days and it decays by beta emission.

**a** Write a balanced equation for the decomposition of P-32.

**b** If the original sample were 275 mg of  $\text{K}_3^{32}\text{PO}_4$ , what amount remains after 37.0 d? What percent of the sample has undergone decay?

**20.101** The half-life of  ${}_{35}^{83}\text{Br}$  is 1.471 days. This isotope decays by the emission of a beta particle.

**a** Gaseous HBr is made with Br-82. When the bromine isotope decays, the HBr produces  $\text{H}_2$  and the bromine decay product. Write a balanced equation for the decay of Br-82. Now, write a balanced equation for the decomposition of  $\text{H}^{82}\text{Br}$ .

**b** If a pure sample of 0.0150 mol of HBr made entirely with Br-82 is placed in an evacuated 1.00-L flask, how much HBr remains after 10.0 h? If the temperature is  $22^\circ\text{C}$ , what is the pressure in the flask?

**20.102** The half-life of  ${}_{52}^{132}\text{Te}$  is 3.26 days. This isotope decays by beta emission to a highly unstable intermediate that decays rapidly to a stable product by beta emission.

**a** What is the ultimate product obtained from Te-132? Write a balanced equation for this reaction.

**b** Gaseous  $\text{H}_2\text{Te}$  is made with Te-132. When the tellurium isotope decays, the  $\text{H}_2\text{Te}$  produces  $\text{H}_2$  and the ultimate decay product of Te-132. Write a balanced equation for the formation of stable products from  $\text{H}_2^{132}\text{Te}$ .

**c** If a pure sample of 0.0125 mol of  $\text{H}_2\text{Te}$  made entirely of Te-132 is placed in an evacuated 1.50-L flask, how much  $\text{H}_2\text{Te}$  remains after 93.0 h? If the temperature is  $25^\circ\text{C}$ , what is the pressure in the flask?

**20.103** How would you describe the structure of the alpha particle in terms of the shell model? Note that the protons and neutrons have their own shell structures. Why would you expect the alpha particle to be especially stable?

**20.104** What are the next three energy levels following the  $1f$  level (before spin-orbit coupling is accounted for)?

**20.105** What is the purpose of a PET scan? What type of substance is administered to a person undergoing a PET scan?

**20.106** The instrument for PET scans actually detects gamma rays. However, the radioactive substance emits another particle. Describe what is happening.

## Strategy Problems

**Key:** As noted earlier, all of the practice and general problems are matched pairs. This section is a selection of problems that are not in matched-pair format. These challenging problems require that you employ many of the concepts and strategies that were developed in the chapter. In some cases, you will have to integrate several concepts and operational skills in order to solve the problem successfully.

**20.107** Complete the following nuclear reactions.

**20.108** What nuclide is formed when americium-241 undergoes alpha decay?

**20.109** Radioisotope thermoelectric generators can be used by satellites to obtain power from radioactive decay of various isotopes, plutonium-238 being the preferred fuel. Plutonium-238 decays via alpha emission and has a half-life of 87.7 years.

**a** Write the nuclear equation for the alpha decay of plutonium-238.

**b** If you were to start with 250.0 g of Pu-238 to power a satellite, what mass would remain after 45 years?

**20.110** Calculate the energy released, in joules per mole, when uranium-238 undergoes alpha decay. See Table 20.3.

**20.111** Consider Rn-222.

**a** Predict the type of radioactive decay that Rn-222 is most likely to undergo.

**b** Write the equation for the decay process.

**c** The half-life of Rn-222 is 3.82 days. If you start with a 150.0-g sample of Rn-222, how much remains after 15.0 days?

**20.112** The gold-198 isotope is used in the treatment of brain, prostate, and ovarian cancer. Au-198 has a half-life of 2.69 d. If a hospital needs to have 25 mg of Au-198 on hand for treatments on a particular day, and shipping takes 72 h, what mass of Au-198 needs to be ordered?

**20.113** The bromine isotope Br-75 is used for imaging in positron emission tomography. Br-75 has a half-life of 57 h. How much time must elapse for a given dose of Br-75 to drop to 25% of its initial amount?

**20.114** The decay of Rb-87 ( $t_{1/2} = 4.8 \times 10^{10}$  y) to Sr-87 has been used to determine the age of ancient rocks and minerals.

**a** Write the balanced nuclear equation for this decay.

**b** If a sample of rock is found to be 0.100% by mass Rb-87 and 0.00250% by mass Sr-87, what is the age of the rock? Assume that there was no Sr-87 present when the rock formed.

**20.115** You have two piles of different unknown radioactive substances: pile A with a mass of 200 g, and pile B with a mass of 100 g. Would it be possible for these two piles to have the same rate of radioactive decay? Explain.

**20.116** Cobalt-60 has a half-life of 5.26 y. Gamma radiation from this isotope is used to treat malignant tumors. What mass of cobalt-60 is required to generate a 500-Ci gamma-ray source?

**20.117** Consider a 1.0-g sample of carbon.

**a** Calculate the amount of energy released (kJ) if the entire mass of the carbon sample could be converted to energy.

**b** Using data from Appendix C, calculate the amount of energy released when the sample of graphite is combusted.

**c** If you had a sample of coal that was pure graphite, what mass of coal would need to be combusted in order to produce an equivalent energy to that calculated in part a?

**20.118** Samarium-153 is used in a drug to treat bone disorders. Sm has an activity of 8.6 Ci per mg.

**a** What is the rate constant of Sm-153?

**b** What is the half-life of Sm-153.

**c** In the United States, pharmaceutical companies can purchase Sm-153 from the National Isotope Development Center at Oak Ridge National Laboratory. A company needs a 500.0-mg sample of Sm-153 to manufacture a bone treatment drug. However, if production is expected to be delayed by 8 weeks after the company has obtained the Sm-153, what mass of Sm-153 will it need to purchase?

**20.119** Radon-222 gas can be found seeping from granite that contains uranium-238. Radon-222 is a nuclide in the radioactive decay series of uranium-238. Radon is an element with a half-life of 3.82 days.

**a** Predict the most likely particle emitted when radon-222 undergoes nuclear decay and write the nuclear equation for the decay.

**b** What is the decay constant ( $k$ ) for radon-222.

**c** The U.S. Environmental Protection Agency recommends that the concentration of radon gas in dwellings not exceed 4 pCi per liter of air. What mass of Rn-222 would be in a 1-L sample of air that had a decay rate of 4 pCi?

**20.120** Plutonium-239 is a fissionable material used in the construction of nuclear weapons and has a half-life of 24,100 years. Approximately  $2 \times 10^4$  kg of plutonium is produced per year. How long would it take for 99.99% of the plutonium produced in one year to decay?

**20.121** Californium-251 was synthesized at the University of California in 1950. What type of decay would you predict for Cf-251? Write the balanced nuclear reaction for this decay.

**20.122** Sodium has only one naturally occurring isotope that is not radioactive.

**a** What is the mass defect of sodium?

**b** What is the nuclear binding energy (MeV) of a sodium nucleon?

## Capstone Problems

**Key:** The problems under this heading combine skills, strategies, and concepts learned in previous chapters with those introduced in the current one.

**20.123** A sample of sodium phosphate,  $\text{Na}_3\text{PO}_4$ , weighing 32.4 mg contains radioactive phosphorus-32 (with mass 32.0 amu). If 22.3% of the phosphorus atoms in the compound is phosphorus-32 (the remainder is naturally occurring phosphorus), how many disintegrations of this nucleus occur per second in this sample? Phosphorus-32 has a half-life of 14.3 d.

**20.124** A sample of sodium thiosulfate,  $\text{Na}_2\text{S}_2\text{O}_3$ , weighing 43.6 mg contains radioactive sulfur-35 (with mass 35.0 amu). If 22.3% of the sulfur atoms in the compound is sulfur-35 (the remainder is naturally occurring sulfur), how many disintegrations of this nucleus occur per second in this sample? Sulfur-35 has a half-life of 87.9 d.

**20.125** Polonium-210 has a half-life of 138.4 days, decaying by alpha emission. Suppose the helium gas originating from the alpha particles in this decay was collected. What volume of helium at 25°C and 735 mmHg could be

obtained from 1.0000 g of polonium dioxide,  $\text{PoO}_2$ , in a period of 48.0 h?

**20.126** Radium-226 decays by alpha emission to radon-222, a noble gas. What volume of pure radon-222 at 23°C and 755 mmHg could be obtained from 543.0 mg of radium bromide,  $\text{RaBr}_2$ , in a period of 37.5 y? The half-life of radium-226 is 1602 years.

**20.127** What is the energy (in joules) evolved when 1 mol of helium-4 nuclei is produced from protons and neutrons? How many liters of ethane,  $\text{C}_2\text{H}_6(g)$ , at 25°C and 725 mmHg are needed to evolve the same quantity of energy when the ethane is burned in oxygen to  $\text{CO}_2(g)$  and  $\text{H}_2\text{O}(g)$ ? See Table 20.3 and Appendix C for data.

**20.128** Plutonium-239 has been used as a power source for heart pacemakers. What is the energy obtained from the following decay of 215 mg of plutonium-239?

Suppose the electric energy produced from this amount of plutonium-239 is 25.0% of this value. What is the minimum grams of zinc that would be needed for the standard voltaic cell  $\text{Zn}|\text{Zn}^{2+}||\text{Cu}^{2+}|\text{Cu}$  to obtain the same electric energy?

Chemistry of the  
Main-Group Elements

The exothermic reaction of sodium metal with water to form sodium hydroxide and hydrogen gas. The yellow emission is from sodium atoms.

© Charles D. Winters

## CONTENTS AND CONCEPTS

We begin our study with some general observations about the main-group elements.

**21.1** General Observations About the Main-Group Elements

### Chemistry of the Main-Group Metals

We first focus on the metals of Groups 1A, 2A, 3A, and 4A. We look at the commercial production of metals and then at bonding in metals.

**21.2** Metals: Characteristics and Production

**21.3** Bonding in Metals

**21.4** Group 1A: The Alkali Metals

**21.5** Group 2A: The Alkaline Earth Metals

**21.6** Group 3A and Group 4A Metals

### Chemistry of the Nonmetals

The nonmetals are elements that do not exhibit metallic characteristics. Almost half of these elements are gases.

**21.7** Hydrogen

**21.8** Group 4A: The Carbon Family

**21.9** Group 5A: Nitrogen and the Phosphorus Family

**21.10** Group 6A: Oxygen and the Sulfur Family

**21.11** Group 7A: The Halogens

**21.12** Group 8A: The Noble Gases

Suppose you were asked to name some important elements. Let's see. There is oxygen in air, which you need to breath to support the oxidation reactions in the mitochondria of your cells that supply your body with energy. Then there is hydrogen, which combines with oxygen to form water. Water is the indispensable medium for most of the life processes that occur in your cells and those of other living things. Then there is carbon, which is central to biological compounds. Carbohydrates (including sugars, starch, and cellulose) and fats and oils contain carbon with hydrogen and oxygen. Proteins are the major structural and functional compounds of living organisms. They are made principally of carbon, hydrogen, oxygen, and nitrogen. These four elements—along with a few others, such as aluminum and silicon—are also among the most abundant elements on earth. They are all *main-group elements*.

Figure 21.1 is an abridged periodic table showing just these elements. Hydrogen is shown here, as it often is, in a group by itself at the top of the table, although it is sometimes placed in Groups 1A and 7A. Carbon is in Group 4A, nitrogen is in Group 5A, and oxygen is in Group 6A. The main-group elements are definitely important to life, but they also play central roles in many everyday applications, as we will see.

A dominant feature of these elements is the pronounced trends in the properties as you go from one group to the other in the periodic table. We will begin this chapter by looking at these and other *general observations* about the main-group elements. Then we will look at the *metallic elements*, describing how the metals are produced from their sources and how the metal atoms chemically bond. And, of course, we will want to look at some individual elements, exploring their physical and chemical properties, as well as their commercial applications. In the final sections of this chapter, we will explore the *nonmetallic elements*.

## 21.1 General Observations About the Main-Group Elements

In this section, we want to consider some periodic trends that you will find useful as you study the chemistry of specific elements. The elements on the left side of the periodic table in Figure 21.1 are largely metallic in character; those on the right side are largely nonmetallic. Table 21.1 compares the characteristics of metallic and nonmetallic elements, and the following discussion describes some of these characteristics in greater detail.

The metallic elements generally have low ionization energies and low electronegativities compared with the nonmetallic elements. As a result, the metals tend to lose their valence electrons to form cations ( $\text{Na}^+$ ,  $\text{Ca}^{2+}$ ,  $\text{Al}^{3+}$ ) in compounds or in aqueous solution. Nonmetals, on the other hand, form monatomic anions ( $\text{O}^{2-}$ ,  $\text{Cl}^-$ ) and oxoanions ( $\text{NO}_3^-$ ,  $\text{SO}_4^{2-}$ ).

Also, as noted earlier (Section 8.7), the oxides of the metals are usually basic. The oxides of the most reactive metals react with water to give basic solutions. For example,

	H							18
	1	2	13	14	15	16	17	8A

Figure 21.1 ▲

An abridged periodic table showing the main-group elements. Elements to the left of the heavy staircase line are largely metallic in character; those to the right are largely nonmetallic.

**Table 21.1** Comparison of Metallic and Nonmetallic Elements

Metals	Nonmetals
Lustrous	Nonlustrous
Solids at 20°C (except Hg, which is a liquid)	Solids or gases at 20°C (except Br <sub>2</sub> , which is a liquid)
Solids are malleable and ductile	Solids are usually hard and brittle
Conductors of heat and electricity	Nonconductors of heat and electricity (except the C allotropes graphite and graphene)
Low ionization energies	Moderate to high ionization energies
Low electronegativities	Moderate to high electronegativities
Form cations	Form monatomic anions or oxoanions
Oxides are basic (unless metal is in a high oxidation state)	Oxides are acidic

[Oxides of metals in high oxidation states, which you encounter in some transition metals, can be acidic; chromium(VI) oxide, CrO<sub>3</sub>, is an acidic oxide.] The oxides of the nonmetals are acidic. Sulfur dioxide, an oxide of a nonmetal, dissolves in water to form an acidic solution.

Silicon dioxide (silica sand) does not dissolve in water, but it does react when melted with basic oxides such as calcium oxide to form salts.

Table 21.2 shows the oxidation states displayed by compounds of the main-group elements. The principal conclusions are as follows: the metallic elements generally have oxidation states equal to the group number (the Roman numeral for a column), representing a loss of the valence electrons in forming compounds. Some of the metallic elements in the fifth and sixth periods also have oxidation states equal to the group number minus two (for example, Pb<sup>2+</sup>). However, the nonmetals (except for the most electronegative elements fluorine and oxygen) have a variety of oxidation states extending from the group number (the most positive value) to the group number minus eight (the most negative value). For example, chlorine (a Group 7A element) has the following oxidation states in compounds: +7, +5, +3, +1, -1.

The metallic–nonmetallic characteristics of the elements change in definite ways as you move from left to right across a period or down a column of the periodic table. *The metallic characteristics of the main-group elements in the periodic table generally decrease in going across a period from left to right.* Figure 21.1 illustrates this in a broad way. In any period, the elements at the far left are metals and those at the far right are nonmetals. The trend of decreasing metallic character can be seen clearly in the third-period elements. Sodium, magnesium, and aluminum are metals. Silicon is a metalloid, whereas phosphorus, sulfur, and chlorine are nonmetals. The oxides of these elements show the expected trend from basic to acidic. Sodium oxide and magnesium oxide are basic. Aluminum oxide is amphoteric (it has basic and acidic character). The oxides of the elements silicon to chlorine are acidic.

*The metallic characteristics of the main-group elements in the periodic table become more important going down any column (group).* This trend is more pronounced in the middle groups of the periodic table (Groups 3A to 5A). For example, in Group 4A, carbon is a nonmetal, silicon and germanium are metalloids, and tin and lead are metals. The metallic elements tend to become more reactive as you progress down a column. You can see this most clearly in the Group 2A elements; beryllium is much less reactive than strontium and barium.

Period	Group						
	1A	2A	3A	4A	5A	6A	7A
2	Li	Be	B	C	N	O	F
	+1	+2	+3	+4	+5	-1	-1
				+2	+4	-2	
				-4	+3		
3	Na	Mg	Al	Si	P	S	Cl
	+1	+2	+3	+4	+5	+6	+7
				-4	+3	+4	+5
					-3	+2	+3
4	K	Ca	Ga	Ge	As	Se	Br
	+1	+2	+3	+4	+5	+6	+7
				+2	+3	+4	+5
					-3	-2	+1
5	Rb	Sr	In	Sn	Sb	Te	I
	+1	+2	+3	+4	+5	+6	+7
			+1	+2	+3	+4	+5
					-3	-2	+1
6	Cs	Ba	Tl	Pb	Bi	Po	At
	+1	+2	+3	+4	+5	+4	+5
			+1	+2	+3	+2	-1

\*The most common oxidation state is shown in color. Some uncommon oxidation states are not shown.

*A second-period element is often rather different from the remaining elements in its group.* The second-period element generally has a small atom that tends to hold electrons strongly, giving rise to a relatively high electronegativity (electron-withdrawing power). For example, nitrogen has an electronegativity of 3.0, but the other Group 5A elements have electronegativities between 1.9 and 2.1. Also, the small atomic size of the second-period elements seems to limit the types of compounds formed. For example, nitrogen only forms trihalides (such as  $\text{NCl}_3$ ), whereas phosphorus, with a relatively larger atomic size, forms both trihalides ( $\text{PCl}_3$ ) and pentahalides ( $\text{PCl}_5$ ).

## ► Chemistry of the Main-Group Metals

In the first half of this chapter, we will focus on the metals in Groups 1A, 2A, 3A, and 4A. We will discuss the preparation of several of these metals in Section 21.2 and the bonding of metals in Section 21.3. Then, in Sections 21.4 to 21.6, we will address

these questions: What are the physical and chemical properties of some of the main-group metallic elements and their compounds? What are some of the commercial uses of these substances?

## 21.2 Metals: Characteristics and Production

One of the obvious characteristics of a metal is its luster, or shine. But metals have other interesting properties, such as their relatively high electrical and heat conductivities. Metals are also more or less malleable and ductile. By *malleable*, we mean you can pound the material into flat sheets; by *ductile*, we mean you can draw it into a wire. Thus we can define a **metal** as *a material that is lustrous (shiny), has high electrical and heat conductivities, and is malleable and ductile*.

A metal need not be a pure element; it can be a compound or mixture. An **alloy** is *a material with metallic properties that is either a compound or a mixture*. If the alloy is a mixture, it may be homogeneous (a solution) or heterogeneous. Most commercial metals are alloys consisting of one metal with small quantities of other metals to add desirable characteristics. For example, aluminum is often alloyed with magnesium and copper for strength.

### Sources of Metals

Metals and their compounds come from various minerals. A **mineral** is *a naturally occurring inorganic solid substance or solid solution with a definite crystalline structure*. Thus a mineral might be a definite chemical substance, or it might be a homogeneous solid mixture. For example, bauxite, from which we obtain aluminum, is a *rock* (a naturally occurring solid material composed of one or more minerals) that contains several aluminum minerals, including gibbsite, a mineral form of aluminum hydroxide,  $\text{Al}(\text{OH})_3$ , and the mineral boehmite, aluminum oxide hydroxide,  $\text{AlO}(\text{OH})$ . Corundum is an oxide mineral of aluminum,  $\text{Al}_2\text{O}_3$ . Some of the aluminum atoms in corundum may be replaced by chromium atoms, forming a mineral that is a red solution of  $\text{Al}_2\text{O}_3$  and  $\text{Cr}_2\text{O}_3$ . When this mineral is of gemstone quality, it is known as ruby (Figure 21.2). An **ore** is *a rock or mineral from which a metal or nonmetal can be economically produced*. Thus bauxite is the principal ore of aluminum.

Jacana/Science Source

**Figure 21.2** ▲

**Ruby** Ruby is aluminum oxide,  $\text{Al}_2\text{O}_3$ , containing a small percentage of chromium(III) oxide,  $\text{Cr}_2\text{O}_3$ .

### Metallurgy

No doubt nuggets of gleaming metal in sand and rock initially fascinated early humans simply because of their appearance. Eventually, however, someone discovered that metals could be fashioned into tools. The first metals used were probably those that occurred naturally in the free state, such as gold. Later, it was found that heating certain rocks in a hot charcoal fire yielded metals. We realize now that these rocks contain metal compounds that can be reduced to the metallic state by reaction with charcoal (carbon) or the carbon monoxide obtained from the partial burning of charcoal. Copper was probably the first metal produced this way. Later, it was discovered that rocks containing copper and tin compounds yielded bronze, the first manufactured alloy. It was from these beginnings that metallurgy arose. **Metallurgy** is *the scientific study of the production of metals from their ores and the making of alloys having various useful properties*. In this section, we will look at the basic steps in the production of a metal from its ore:

1. *Preliminary treatment.* Usually, an ore must first be treated in some way to concentrate its metal-containing portion. Ores are usually mixtures of a mineral containing the metal along with economically worthless rock material that must be discarded. During the preliminary treatment, the metal-containing mineral is separated from these less desirable parts of the ore. It may also be necessary to transform the metal-containing mineral by chemical reaction to a metal compound that is more easily reduced to the free metal.

2. *Reduction.* Unless the metal occurs free, the metal compound obtained from preliminary treatment has to be reduced. Electrolysis or chemical reduction may be used, depending on the metal.
3. *Refining.* Once the free metal is obtained, it may have to be purified before it can be used. This purification process is referred to as metal refining.

### Preliminary Treatment

A metal ore contains varying quantities of economically worthless material along with the mineral containing the metallic element. To separate the useful mineral from an ore, both physical and chemical methods are used. Panning for gold nuggets is a simple physical separation method based on differences in densities of gold and other minerals. Flushing water over a pan of gold-bearing earth easily washes sand and dirt aside, leaving the more dense grains of gold at the bottom of the pan.

The Bayer process is an example of a chemical method of concentrating an ore in its metal-bearing fraction. The **Bayer process** is a *chemical procedure in which purified aluminum oxide,  $Al_2O_3$ , is separated from the aluminum ore bauxite.* It depends on the fact that aluminum hydroxide is amphoteric, meaning that it behaves both as a base (reacting with acid to form the metal ion), which is expected of a metal hydroxide, and as an acid (reacting with base to form a hydroxo metal ion). Bauxite, as we noted earlier, contains aluminum hydroxide,  $Al(OH)_3$ , and aluminum oxide hydroxide,  $AlO(OH)$ , as well as relatively worthless constituents such as silicate minerals with some iron oxides. When bauxite is mixed with hot, aqueous sodium hydroxide solution, the amphoteric aluminum minerals, along with some silicates, dissolve in the strong base. The aluminum minerals give the aluminate ion,  $Al(OH)_4^-$ .

Other substances, including the iron oxides, remain undissolved and are filtered off. As the hot solution of sodium aluminate cools, aluminum hydroxide precipitates, leaving the soluble silicates in solution. In practice, the solution is seeded with aluminum hydroxide to start the precipitation.

Aluminum hydroxide can also be precipitated from the basic solution by acidifying it with carbon dioxide gas (Figure 21.3). The aluminum hydroxide is finally *calcined* (heated strongly in a furnace) to produce aluminum oxide.

Bauxite is also a source of gallium, the element under aluminum in the periodic table. Gallium is important in preparing gallium arsenide for solid-state devices, including lasers for compact disc players and light-emitting diodes, or LEDs (Figure 21.4). Sodium gallate,  $Na[Ga(OH)_4]$ , is more soluble than the corresponding aluminum compound, and it remains in the filtrate from the Bayer process after aluminum hydroxide has been filtered off.

Once an ore is concentrated, it may be necessary to convert the mineral to a compound more suitable for reduction. **Roasting** is the *process of heating a mineral in air to obtain the oxide.* Sulfide minerals, such as lead ore (containing the mineral galena,  $PbS$ ), are usually roasted before reducing them to the metal.

The roasting process is exothermic, because it is essentially the burning of the sulfide ore. Once the ore has been heated to initiate roasting, additional heating is unnecessary.

### Reduction

A metal, if it is not already free, must be obtained from one of its compounds by reduction, using either electrolysis or chemical reduction.

Figure 21.3 ►

**Precipitation of aluminum hydroxide by acidifying an aluminate ion solution**

Carbon dioxide gas is bubbled into a solution of aluminate ion,  $\text{Al}(\text{OH})_4^-$ , containing aluminon dye.

Aluminum hydroxide,  $\text{Al}(\text{OH})_3$ , precipitates from the acidic solution. The precipitate is normally white but adsorbs the dye to form a pink-colored precipitate called a *lake*. A standard test for aluminum ion is its precipitation as the hydroxide in the presence of aluminon dye to form this lake.

Hank Morgan/Science Source

Figure 21.4 ▲

**Preparation of gallium arsenide, GaAs, semiconductor material** The bars in the tube are gallium; the small pieces in the tube near the furnace are arsenic.

Gallium arsenide is used to make semiconductor diode lasers for use in fiber optic communications, compact disc players, and laser printers. Also, computer chips are being developed using gallium arsenide, because it conducts an electrical signal five times faster than presently used silicon.

**Electrolysis** The reactive main-group metals, such as lithium, are obtained by *electrolysis*. Electrolysis uses an electric current to reduce a metal compound to the metal. Lithium, for example, is obtained commercially by electrolysis of molten lithium chloride,  $\text{LiCl}$ . (The industrial process uses a mixture of  $\text{LiCl}$  and  $\text{KCl}$  melting at  $450^\circ\text{C}$ , which is lower than the melting point of pure  $\text{LiCl}$  at  $613^\circ\text{C}$ .) Molten lithium chloride is a liquid consisting of lithium ions,  $\text{Li}^+$ , and chloride ions,  $\text{Cl}^-$ . Electrons from the negative pole of a battery flow to an attached electrode and react with lithium ions in the melt, forming lithium metal:

At the other electrode, chloride ions yield chlorine gas, and electrons flow back to the battery.

The net result of these electrode reactions is the production of lithium metal and chlorine from lithium chloride. The electric current supplies the energy for the reaction.

Magnesium is another reactive metal obtained by electrolysis of the chloride. Magnesium ion,  $\text{Mg}^{2+}$ , is the third most abundant dissolved ion in the oceans, after  $\text{Cl}^-$  and  $\text{Na}^+$ . The oceans, therefore, are an essentially inexhaustible supply of magnesium ion, from which the metal can be obtained. The **Dow process**, a commercial method for isolating magnesium from seawater, depends on the fact that magnesium ion can be precipitated from aqueous solution by adding a base. Figure 21.5 shows a flowchart for the process. Seashells provide the source of the

**Figure 21.5** ▲

**Dow process for producing magnesium from seawater** Oyster shells or other seashells are calcined in a kiln to produce calcium oxide, which when added to seawater precipitates magnesium ion as magnesium hydroxide. This is neutralized with hydrochloric acid to give magnesium chloride. Electrolysis of molten  $\text{MgCl}_2$  yields magnesium metal and chlorine. Hydrochloric acid can be recovered by burning the chlorine with natural gas.

base (calcium hydroxide). Seashells are principally calcium carbonate,  $\text{CaCO}_3$ , which when heated decomposes to calcium oxide,  $\text{CaO}$ , and carbon dioxide,  $\text{CO}_2$ . Calcium oxide reacts with water to produce calcium hydroxide. The base, calcium hydroxide, provides hydroxide ion that reacts with magnesium ion in seawater to precipitate magnesium hydroxide:

The magnesium hydroxide is allowed to settle out in ponds; here it gives a suspension, or slurry, of  $\text{Mg}(\text{OH})_2$ . The slurry is filtered to recover the magnesium hydroxide precipitate, which is then treated with hydrochloric acid to yield magnesium chloride. The dry magnesium chloride salt is melted and electrolyzed at  $700^\circ\text{C}$  to yield magnesium metal and chlorine gas. ►

Aluminum is manufactured from the aluminum oxide obtained in the Bayer process using electrolysis. The method for doing this was discovered in 1886 by Charles Martin Hall (then a student at Oberlin College) in the United States and, independently, by Paul Héroult in France.

The **Hall–Héroult process** is the commercial method for producing aluminum by the electrolysis of a molten mixture of aluminum oxide in cryolite,  $\text{Na}_3\text{AlF}_6$ . Originally, the process used natural cryolite as the molten solvent. Today, the Hall–Héroult process uses synthetic cryolite, or sodium hexafluoroaluminate, produced by reacting aluminum hydroxide from the Bayer process with sodium hydroxide and hydrofluoric acid.

A Hall–Héroult electrolytic cell consists of a rectangular steel shell lined first with an insulating material, then with carbon (from baked petroleum coke) to form the negative electrode (Figure 21.6). The other (positive) electrode is also made

Magnesium is also produced by the chemical reduction of magnesium oxide,  $\text{MgO}$ , by silicon,  $\text{Si}$ . China is a major producer of magnesium metal, using this process.

Figure 21.6 ▶

**Hall-Héroult cell for the production of aluminum**

Aluminum oxide is electrolyzed in molten cryolite (the electrolyte). Molten aluminum forms at the negative electrode (tank lining), where it is periodically withdrawn.

from carbon. The electrolyte consists of molten cryolite, at about 1000°C, into which some aluminum oxide is dissolved. The overall electrolysis reaction is

The positive carbon electrodes are consumed in the electrolysis and must be replaced periodically; aluminum oxide is continually added to the electrolyte bath.

**Chemical Reduction** The cheapest chemical reducing agent is some form of carbon, such as hard coal or coke. Coke is the solid residue left from coal after its volatile constituents have been driven off by heating in the absence of air. Some important metals, including iron and zinc, are obtained by reduction of their compounds with carbon (or carbon monoxide, which is a product of partial oxidation of carbon).

Earlier, we described how lead is obtained from its sulfide ore by roasting it to lead(II) oxide. When the oxide is heated strongly with carbon in a *blast furnace*, it is reduced to the metal. Lead(II) oxide and coke are added at the top of the furnace; a blast of air enters at the bottom. Some of the coke burns in the air and heats the material to a high temperature. The lead(II) oxide reacts with carbon:

Liquid lead collects at the bottom of the furnace, where it is drawn off.

**Refining**

Often the metal obtained from the reduction process contains impurities and must be purified, or *refined*. Various refining techniques are used. For example, zinc is easily vaporized (it boils at 908°C), so it is purified by distillation. Lead is purified by blowing air through the liquid metal to oxidize impurities, including carbon and sulfur. Copper is purified by electrolysis, in which the impure copper forms the positive pole and pure copper the negative. Copper ions flow from the impure copper and collect on the pure copper. See Figure 19.24.

**21.3 Bonding in Metals**

The special properties of a metal result from its delocalized bonding, in which bonding electrons are spread over a number of atoms. In this section, we will look first at the “electron-sea” model of a metal and then at the molecular orbital theory of bonding in metals.

**Electron-Sea Model of Metals**

A very simple picture of a metal depicts an array of positive ions surrounded by a “sea” of valence electrons free to move over the entire metal crystal. When the metal is connected to a source of electric current, the electrons easily move away from the negative side of the electric source and toward the positive side, forming an electric current in the metal. In other words, the metal is a conductor of

electric current because of the mobility of the valence electrons. A metal is also a good heat conductor because the mobile electrons can carry additional kinetic energy across the metal. ►

### Molecular Orbital Theory of Metals

The electron-sea model of metals is a simplified view that accounts in only a qualitative way for properties of a metal such as electrical conductivity. Molecular orbital theory gives a more detailed picture of the bonding in a metal and other solids as well. ►

Recall that molecular orbitals form between two atoms when atomic orbitals on the atoms overlap. In some cases, the atomic orbitals on three or more atoms overlap to form molecular orbitals that encompass all of the atoms. These molecular orbitals are said to be *delocalized*. The number of molecular orbitals that form by the overlap of atomic orbitals always equals the number of atomic orbitals. In a metal, the outer orbitals of an enormous number of metal atoms overlap to form an enormous number of molecular orbitals that are delocalized over the metal. As a result, a large number of energy levels are crowded together into “bands.” Because of these energy bands, the molecular orbital theory of metals is often referred to as *band theory*.

Sodium metal provides a simple illustration of band theory. Imagine that you build a crystal of sodium by bringing sodium atoms together one at a time, and during this process you follow the formation of molecular orbitals and associated energy levels. Each isolated sodium atom has the electron configuration  $1s^22s^22p^63s^1$ , or  $[\text{Ne}]3s^1$ . When two sodium atoms approach each other, their  $3s$  orbitals overlap to form two molecular orbitals (a bonding molecular orbital and an antibonding molecular orbital). The inner-core electrons, represented as  $[\text{Ne}]$  in the electron configuration, remain essentially nonbonding. Now imagine that a third atom is brought up to this diatomic molecule. The three  $3s$  orbitals overlap to form three molecular orbitals, each orbital encompassing the entire  $\text{Na}_3$  molecule (that is, they are delocalized over the molecule). When a large number  $N$  (on the order of Avogadro’s number) of sodium atoms have been brought together to form a crystal, the atoms will have formed  $N$  molecular orbitals encompassing the entire crystal.

Figure 21.7 shows that at each stage the number of energy levels grows. Eventually, the energy levels effectively merge into a *band* of continuous energies. We call this the  $3s$  band of the sodium metal. A  $3s$  band formed from  $N$  atoms will have  $N$  orbitals that hold a maximum of  $2N$  electrons. Because each sodium atom has one valence electron,  $N$  atoms will supply  $N$   $3s$  electrons and will therefore half-fill the  $3s$  band.

We can now explain the electrical conductivity of sodium metal. Electrons become free to move throughout a crystal when they are excited to unoccupied orbitals of a band. In sodium metal, this requires very little energy; because of the half-filled  $3s$  band, unoccupied orbitals lie just above the occupied orbitals of highest energy. When a voltage is applied to a metal crystal, electrons are excited to the unoccupied orbitals and move toward the positive pole of the voltage source. A current flows in the metal.

The electron-sea model of metallic bonding is described briefly in Section 9.7; see Figure 9.18.

Molecular orbital theory is discussed in Sections 10.5 to 10.7.

**Figure 21.7** ◀

**Formation of an energy band in sodium metal** Note that the number of energy levels grows until the levels merge into a continuous band of energies. The lower half of the band is occupied by electrons.

Figure 21.8 ►

**Formation of 3s and 3p bands in magnesium metal** Note that the 3s and 3p bands merge. As a result, the bands are only partially filled.

The explanation of the electrical conductivity of magnesium metal is somewhat more complicated than in the case of sodium. A magnesium atom has the configuration  $[\text{Ne}]3s^2$ . As in sodium, the 3s orbitals of magnesium metal overlap to form a 3s band. If this were the whole story, you would expect the  $2N$  valence electrons of the atoms to completely fill the 3s band. Therefore, if a small voltage were applied, the electrons would have no place to go. You would expect magnesium to be an insulator (a nonconducting material), but in fact it is a conductor.

Both sodium and magnesium have unoccupied 3p bands formed from unoccupied 3p orbitals of the atoms. The presence of this band in sodium has no effect on its electrical conductivity. In magnesium, however, the situation is different, as Figure 21.8 shows. As the orbitals of the individual atoms interact in forming the metal, the energy levels spread so that the bottom of the 3p band merges with the top of the 3s band. Imagine electrons filling the 3s band. When the electrons reach the energy where the two bands have merged, electrons begin to fill orbitals in both bands. As a result, the 3s and 3p bands of magnesium metal are only partially filled by the time you have accounted for all  $2N$  valence electrons. Therefore, when a voltage is applied to the metal, the highest-energy electrons are easily excited into the unoccupied orbitals, giving an electrical conductor.

In general, a solid that has a partially filled band will be an electrical conductor. A solid that has only completely filled bands (without a nearby unfilled band) will be a nonconductor of electricity, or electrical insulator.

## 21.4 Group 1A: The Alkali Metals

The alkali metals, the elements in the first column of the periodic table except hydrogen, are all soft, silvery metals. Figure 21.10 shows sodium metal being cut with a knife. The alkali metals are the most reactive of all metals, reacting readily with air and water. Because the valence configuration of these elements is  $ns^1$ , the alkali metals usually react by losing this electron to form the +1 ions, such as  $\text{Li}^+$  and  $\text{Na}^+$ . Most of the compounds of these ions are soluble in water.

Because of their chemical reactivity, the Group 1A elements never occur as free metals in nature. They do occur extensively in silicate minerals, which weather to form soluble compounds of the elements (particularly of sodium and potassium). These soluble compounds eventually find their way to landlocked lakes and oceans, where they concentrate. Enormous underground beds of sodium and potassium compounds formed when lakes and seas became isolated by geologic events; the water eventually evaporated, leaving solid deposits of alkali metal compounds. Commercially, sodium and potassium compounds are common, and both sodium and lithium metals are available in quantity.

## Materials

A CHEMIST Looks at . . .

## Superconductivity

A *superconductor* is a material that abruptly loses its resistance to an electric current when cooled to a definite characteristic temperature. This means that an electric current will flow in a superconductor without heat loss, unlike the current in a typical conductor. Once a current has been started in a superconducting circuit, it continues to flow indefinitely. Another intriguing property of a superconductor is its perfect diamagnetism. This means that the superconductor completely repels magnetic field lines. Figure 21.9 shows a magnet suspended in midair over one of the newly discovered ceramic superconductors. The magnet seems to levitate—it appears to hover in air in defiance of gravity. In fact, the repulsion of magnetic field lines by the superconductor holds the magnet aloft.

Argonne National Laboratory

Figure 21.9 ▲

**Levitation of a magnet by a superconductor** The magnet (samarium–cobalt alloy) is supported above the ceramic superconductor (approximate formula  $\text{YBa}_2\text{Cu}_3\text{O}_7$ ). The ceramic becomes superconducting when it is cooled by liquid nitrogen.

Superconductivity was discovered in 1911 by the Dutch physicist Heike Kamerlingh Onnes soon after he found a way to liquefy helium. By evaporating liquid helium, he could obtain temperatures near absolute zero. Kamerlingh Onnes found that mercury metal suddenly loses all resistance to an electric current when cooled to 4 K. Superconductors first became useful when a niobium metal alloy was found to become superconducting at about 23 K and to remain superconducting even when large currents flow through it. (Many superconducting materials lose their superconductivity when even moderate currents flow through them.) It became possible to construct superconducting magnets with high magnetic fields by starting an electric current in a superconducting circuit. Such magnets are being used in medical magnetic resonance imaging. (See Instrumental Methods: Nuclear Magnetic Resonance in Chapter 8.) Even though expensive liquid helium (more than \$50 per gallon) is needed to operate these magnets, they are still cheaper to use than the usual electromagnets because of their much lower power requirements.

In 1986, Johannes Georg Bednorz and Karl Alexander Müller of IBM discovered that certain copper oxide ceramic materials became superconducting at 30 K, and more recently researchers have found similar materials that become superconducting at 138 K. (Bednorz and Müller won the 1987 Nobel Prize in physics for their discovery.) This means that superconductors could be operated using a cheap refrigerant, such as liquid nitrogen, at a little over a dollar per gallon. Perhaps materials can be found that are superconducting even at room temperature. What remains is to determine how to fabricate such superconducting materials into wires and similar objects with the ability to carry large currents.

■ See Problems 21.191 and 21.192.

## Lithium

In recent years, the commercial importance of lithium metal has risen markedly. Among the alkali metals, only sodium metal is more important.

As you might expect for an alkali metal, lithium is chemically reactive. Like the other alkali metals, it is a relatively soft metal, although the hardest of the Group 1A elements. Lithium does exhibit properties that are somewhat different from those of the lower members of the Group 1A elements. Many of its ionic compounds are much less soluble than are similar compounds of the other alkali metals. Lithium carbonate,  $\text{Li}_2\text{CO}_3$ , for example, is only slightly soluble in water at room temperature, whereas sodium carbonate,  $\text{Na}_2\text{CO}_3$ , is soluble.

Figure 21.12 ▲

**Lithium batteries** Lithium batteries are used wherever a reliable current is required for a lengthy period.

**Lithium Metallurgy** Lithium metal is obtained commercially by processing brine solutions obtained from underground sources that contain lithium ions, as well as ions of other alkali metals. The lithium ore spodumene, which is a lithium aluminum silicate,  $\text{LiAl}(\text{SiO}_3)_2$ , is also a commercial source of lithium. To obtain lithium from the ore, the ore is heated and then washed with sulfuric acid to obtain a solution of lithium ion. Lithium is obtained from solutions of alkali metal ions by precipitating it as lithium carbonate. Lithium carbonate is the primary starting substance for the production of lithium metal and lithium compounds. Lithium metal is obtained by electrolysis of the chloride.

The use of lithium metal has greatly expanded in recent years (Figure 21.11). A major use is in the production of low-density aluminum alloy for aircraft construction. Batteries with lithium metal anodes have also become common (Figure 21.12). The anode reaction is the oxidation of lithium to the ion:

The cathode material varies, but the cathodes in batteries used in cameras, calculators, and similar devices consist of manganese(II) oxide, the same substance used in common dry cells. The electrolyte in this  $\text{Li}/\text{MnO}_2$  cell is a solution of lithium perchlorate,  $\text{LiClO}_4$ , dissolved in an organic solvent.

**Reactions of Lithium Metal** Lithium, like the other alkali metals, reacts readily with water and with moisture in the air to produce lithium hydroxide and hydrogen gas:

When a pellet of lithium is placed in water, the pellet spins around on the surface of the water, evolving bubbles of hydrogen gas. (Lithium floats because it is less dense than water.) The reaction is not as vigorous, however, as the similar reaction of sodium and water.

Lithium burns in air to produce lithium oxide,  $\text{Li}_2\text{O}$ , a white powder.

When heated with nitrogen gas, lithium reacts to form lithium nitride,  $\text{Li}_3\text{N}$ , the only stable alkali-metal nitride.

Lithium nitride is an ionic compound of the nitride ion,  $\text{N}^{3-}$ .

**Lithium Compounds** Lithium carbonate is the primary source of other lithium compounds. Significant quantities of lithium carbonate are also used in the preparation of porcelain enamels, glazes, and special glass. When purified, the carbonate is used as a source of lithium ion for the treatment of bipolar disorder. The physiological action of lithium ion in this treatment is not completely understood, although lithium ion is believed to inhibit certain biochemical reactions involved in the action of neurotransmitters in the brain.

Lithium hydroxide,  $\text{LiOH}$ , is a strong base. It is produced by reaction of lithium carbonate with calcium hydroxide in a precipitation reaction. Calcium carbonate is much less soluble than lithium carbonate:

The calcium carbonate is filtered off, and lithium hydroxide is recovered from the filtrate. Lithium hydroxide is used in the production of lithium soaps, which are used in making lubricating greases from oil. (Lithium soap thickens the oil.) Soaps are salts of fatty acids; they are prepared by heating a fat with a strong base.

Lithium hydroxide is used to remove carbon dioxide from the air in spacecraft and submarines. Humans exhale carbon dioxide that is produced by the normal biochemical reactions of the body. For people to live in a closed space, it is necessary to remove this carbon dioxide. Although carbon dioxide is not normally toxic, increasing concentrations do have a physiological effect by interfering with the

blood's capacity to carry oxygen, and high concentrations of carbon dioxide are hazardous. Like the other alkali-metal hydroxides, lithium hydroxide absorbs carbon dioxide from air by forming the carbonate and hydrogen carbonate:

Sodium hydroxide could be used to remove carbon dioxide from air, since it undergoes the same reactions. However, the formula weight of LiOH (24 amu) is much lower than that of NaOH (40 amu). Where light weight is important, lithium hydroxide is preferred, even though it is more expensive than sodium hydroxide.

Table 21.3 lists some uses of lithium and other alkali metal compounds.

### Sodium and Potassium

Sodium compounds are of enormous economic importance. Common table salt, which is sodium chloride, has been an important article of commerce since earliest recorded history. Salt was of such importance in Roman times that a specific allowance of salt was part of the soldiers' pay. The word *salary* derives from the Latin word for this salt allowance (*salarium*, which comes from the Latin word *sal*, for "salt"). Sodium metal and sodium compounds are produced from sodium chloride.

Compound	Use
Li <sub>2</sub> CO <sub>3</sub>	Preparation of porcelain, glazes, special glasses Preparation of LiOH Treatment of bipolar disorder
LiOH	Manufacture of lithium soaps for lubricating greases In air-regeneration systems
LiH	Reducing agent in organic syntheses
LiNH <sub>2</sub>	Preparation of antihistamines and other pharmaceuticals
NaCl	Source of sodium and sodium compounds Condiment and food preservative Soap manufacture (precipitates soap from reaction mixture)
NaOH	Pulp and paper industry Extraction of aluminum oxide from ore Manufacture of viscose rayon Petroleum refining Manufacture of soap
Na <sub>2</sub> CO <sub>3</sub>	Manufacture of glass In detergents and water softeners
Na <sub>2</sub> O <sub>2</sub>	Textile bleach
NaNH <sub>2</sub>	Preparation of indigo dye for denim (blue jeans)
KCl	Fertilizer Source of other potassium compounds
KOH	Manufacture of soft soap Manufacture of other potassium compounds
K <sub>2</sub> CO <sub>3</sub>	Manufacture of glass
KNO <sub>3</sub>	Fertilizers Explosives and fireworks

The economic importance of potassium stems in large part from its role as a plant nutrient. Enormous quantities of potassium chloride from underground deposits are used as fertilizer to increase the world's food supply. In fact, plants were an early source of potassium compounds. Wood and other plant materials were burned to give ashes that were leached in pots to give potash, which consists primarily of potassium carbonate. The name potassium has its origin in the word *potash* from this earlier source of the element.

Sodium metal is more reactive than lithium metal, and potassium metal is still more reactive. In general, as you move down the column of alkali metals in Group 1A of the periodic table, you find that the metals become more chemically reactive (forming the +1 ions). This is partly a result of the decrease in ionization energy of the atom (from 520 kJ/mol for the first ionization of lithium to 376 kJ/mol for that of cesium). As the atomic size increases going from the top of the column to the bottom, the valence electrons are held less strongly and so are lost more easily.

The Group 1A metals also increase in softness going from the top of the column to the bottom. Lithium is a moderately firm metal, whereas potassium is soft enough to be cut with a butter knife. This increasing softness of the metals is in part a result of increasing atomic size, which results in decreasing strength of bonding by the valence-shell *s* electrons.

**Sodium Metallurgy** Sodium metal is obtained by the electrolysis of molten, or fused, sodium chloride. Sodium chloride is mined from huge underground deposits. The other source of sodium chloride is seawater, which is a solution of many dissolved substances, but sodium chloride is the principal one. Sodium chloride melts at 801°C, but commercial electrolysis employs a mixture of NaCl and CaCl<sub>2</sub>, which melts at 580°C. We discussed the electrolysis in some detail in Section 19.9. ◀

Sodium metal is a strong reducing agent, and this accounts for many of its major uses. For example, it is used to obtain metals such as titanium and zirconium by reduction of their compounds. Titanium is a strong metal used in airplane and spacecraft manufacture. It is produced by reduction of titanium tetrachloride, TiCl<sub>4</sub>, obtained by chemical processing of titanium ores. The overall process can be written as follows:

Sodium is also employed as a reducing agent in the production of a number of organic compounds, including dyes and pharmaceutical drugs.

**Reactions of Sodium Metal** Like lithium, sodium metal reacts with water, but with even greater vigor. The reaction is sufficiently exothermic to ignite the hydrogen gas produced in the reaction:

Sodium burns in air, producing some sodium oxide, Na<sub>2</sub>O, but mainly sodium peroxide, Na<sub>2</sub>O<sub>2</sub>, a compound containing the peroxide ion O<sub>2</sub><sup>2-</sup> (Figure 21.13).

The peroxide ion acts as an oxidizing agent (Figure 21.14).

**Sodium Compounds** Sodium hydroxide, NaOH, is among the top ten industrial chemicals. It is produced by the electrolysis of aqueous sodium chloride. The overall electrolysis, which was described in Section 19.10, can be written as

Both chlorine gas and sodium hydroxide are major products of this electrolysis. ◀

Sodium hydroxide is a strong base, and this property is useful in many applications. It is used in large quantities in aluminum production (which depends on its reaction with the amphoteric aluminum hydroxide) and in the refining of petroleum (where it chemically reacts with acid constituents during the refining process).

Figure 19.20 depicts the commercial Downs cell for the preparation of sodium from molten sodium chloride.

**Figure 21.13** ▲

**Oxygen compounds of alkali metals** Sodium peroxide, Na<sub>2</sub>O<sub>2</sub> (yellowish white, *top*), and potassium superoxide, KO<sub>2</sub> (orange-yellow, *bottom*). Potassium superoxide is the principal product formed when potassium metal burns in air.

Figures 19.22 and 19.23 show two different commercial cells for the electrolysis of aqueous sodium chloride.

**Figure 21.14** ◀  
Sodium peroxide as an oxidizing agent

A couple of drops of water are added to a mixture of sodium peroxide and sulfur to initiate a reaction.

During the violent reaction, sulfur is oxidized to sulfur dioxide.

Large quantities of sodium hydroxide are also used to produce sodium compounds, which occur in a wide variety of commercial products.

For example, soap is made by heating a fat with sodium hydroxide solution. The product is a mixture of sodium salts of fatty acids, obtained from the fat. Fatty acids are chemically similar to acetic acid, but they consist of long chains of carbon atoms. Compare the structure of the acetate ion with that of the stearate ion. (Stearic acid is a typical fatty acid.) ▶

The action of soap in dispersing oil in water is described in Section 12.9.

Sodium hydroxide is commonly known as lye or caustic soda. You can buy it in a grocery store as a drain opener and as an oven cleaner (Figure 21.15). Both usages depend on the reaction of sodium hydroxide with organic materials, such as fats and hair, to produce soluble materials. Because of these reactions, sodium hydroxide and its solutions require careful handling.

Sodium carbonate is another important compound of sodium. The anhydrous compound,  $\text{Na}_2\text{CO}_3$ , is known commercially as *soda ash*. Large quantities of soda ash are consumed with sand and lime in making glass. ▶ The decahydrate,  $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$ , is added to many detergent preparations and is sold commercially as washing soda. In the United States, most sodium carbonate is produced from the mineral trona, whose chemical formula is approximately  $\text{Na}_2\text{CO}_3 \cdot \text{NaHCO}_3 \cdot 2\text{H}_2\text{O}$ . There are large deposits of trona in southwestern Wyoming.

Worldwide, a large fraction of sodium carbonate is still produced by the Solvay process. The **Solvay process** is an industrial method for obtaining sodium carbonate

Soda ash decomposes to sodium oxide when heated. Sodium and calcium oxides, which are basic oxides, react with fused silicon dioxide,  $\text{SiO}_2$ , an acidic oxide, to produce silicate glass.

Figure 21.15 ▼

Sodium compounds available at the grocery store

Figure 21.16 ▲

Laboratory demonstration of the Solvay process

from sodium chloride and limestone. In the main step of this process, ammonia is first dissolved in a saturated solution of sodium chloride. Then carbon dioxide is bubbled in, and sodium hydrogen carbonate (baking soda) precipitates. Figure 21.16 shows a laboratory demonstration of this reaction.

You can think of this as an exchange reaction of  $\text{NH}_4\text{HCO}_3$  (from  $\text{NH}_3 + \text{H}_2\text{CO}_3$ ) with  $\text{NaCl}$ , to give the products  $\text{NaHCO}_3$  and  $\text{NH}_4\text{Cl}$ . The sodium hydrogen carbonate is filtered from the solution. When heated to  $175^\circ\text{C}$ , it decomposes to sodium carbonate.

The reaction to produce sodium hydrogen carbonate uses relatively expensive ammonia. The industrial Solvay process illustrates how you can affect the economics of a process by the ingenious use of raw materials and by recycling intermediate products. Carbon dioxide for the industrial process is obtained by heating limestone ( $\text{CaCO}_3$ ):

The calcium oxide is used to recover ammonia from the ammonium chloride obtained from the preparation of sodium hydrogen carbonate.

The carbon dioxide obtained when sodium hydrogen carbonate is heated to form sodium carbonate is also recycled to prepare more sodium hydrogen carbonate. The overall result of these steps in the industrial Solvay process is the reaction of limestone ( $\text{CaCO}_3$ ) and salt ( $\text{NaCl}$ ) to produce sodium carbonate and calcium chloride:

The raw materials (limestone and salt) are cheap, and for many years the Solvay process was the principal source of sodium carbonate. Unfortunately, there is not sufficient

demand for the by-product calcium chloride. Some is used for deicing of roads, but much of it has to be disposed of as waste. The environmental cost of this waste disposal has made the Solvay process increasingly less attractive.

**Potassium and Potassium Compounds** The principal source of potassium and potassium compounds is potassium chloride, KCl, which is obtained from underground deposits. Small amounts of this salt are used to prepare the metal. Potassium is prepared by the chemical reduction of potassium chloride rather than by electrolysis of the molten chloride, as in the preparation of sodium. In the commercial process, potassium chloride is melted with sodium metal by heating to 870°C.

At this temperature, potassium forms as a vapor. The reaction goes in the direction written because potassium vapor leaves the reaction chamber and is condensed.

Some potassium metal is used to prepare sodium–potassium alloy, which is used as a heat-transfer medium in certain types of nuclear reactors. Most of the potassium metal produced is used in the preparation of potassium superoxide,  $\text{KO}_2$ , for self-contained breathing apparatus used in situations, such as firefighting, where toxic fumes may be present. When potassium burns in air, it produces potassium superoxide:

(The superoxide ion is  $\text{O}_2^-$ , and the oxidation state of oxygen in this ion is  $-\frac{1}{2}$ .) In a self-contained breathing apparatus, the potassium superoxide is contained in a canister through which one's breath passes. Moisture in the breath attacks the superoxide, releasing oxygen.

The potassium hydroxide produced in this reaction removes the carbon dioxide from the exhaled air. The net effect of the self-contained breathing apparatus is to remove moisture and carbon dioxide from exhaled air and provide oxygen.

More than 90% of the potassium chloride that is mined is used directly as a plant fertilizer. The rest is used in the preparation of potassium compounds. Potassium hydroxide, used in the manufacture of liquid soaps, is obtained by the electrolysis of aqueous potassium chloride. Potassium nitrate is prepared by the reaction of potassium hydroxide and nitric acid. This compound is used in fertilizers and for explosives and fireworks. (Table 21.3 summarizes the major uses of potassium compounds, as well as those of lithium and sodium.)

## 21.5 Group 2A: The Alkaline Earth Metals

The Group 2A elements are also known as the alkaline earth metals. These metals exhibit the expected periodic trends. If you compare an alkaline earth metal with the alkali metal in the same period, you see that the alkaline earth metal is less reactive and a harder metal. For example, lithium reacts readily with water, but beryllium reacts hardly at all even with steam. Lithium is a soft metal, whereas beryllium is hard enough to scratch glass. You also see the expected trend within the column of alkaline earth metals; the elements at the bottom of the column are more reactive and are softer metals than those at the top of the column (Figure 21.17). Barium, in the sixth period, is a very reactive metal and, when placed in water, reacts much like an alkali metal. It is also a soft metal, much like the alkali metals. Magnesium, in the third period, is much less reactive and a harder metal (comparable to aluminum).

As we noted in Section 21.1, a second-period element is often considerably different from the other elements in its column. Those differences become more pronounced as you progress to the right in the periodic table. We briefly noted differences in properties of lithium from those of the other alkali metals, though those differences are not great. Beryllium, however, shows rather marked differences from the other alkaline earth elements. We have already noted that beryllium differs

### Magnesium and barium metals

Magnesium metal turnings are in the beaker (left). Barium metal (right) is much more reactive than magnesium and must be stored in a bottle of kerosene to exclude moisture and oxygen, with which barium reacts.

in its lack of reactivity compared with the other Group 2A metals. Another notable difference is in the properties of the hydroxides. Whereas those of the elements magnesium to barium are basic, beryllium hydroxide is amphoteric, reacting with both acids and bases.

Like the alkali metals, the Group 2A elements occur in nature as silicate rocks. They also occur as carbonates and sulfates, and many of these are commercial sources of alkaline earth metals and compounds.

Calcium and magnesium are the most common and commercially useful of the alkaline earth elements, and we will consider them in some detail in the next two subsections. Calcium is the fifth, and magnesium the eighth, most abundant element in the earth's crust.

## Magnesium

The name *magnesium* comes from the name of the mineral magnesite, which in turn is believed to stem from the name *Magnesia*, a site in northern Greece where various minerals, including those of magnesium, have been mined since ancient times. The British chemist Humphry Davy discovered the pure element magnesium in 1808. Davy had already discovered the alkali metals potassium and sodium in late 1807. Several months later, he managed to isolate in quick succession the alkaline earth metals barium, strontium, calcium, and finally magnesium. He obtained magnesium by a procedure similar to the one he used for the other alkaline earths. He electrolyzed a moist mixture of magnesium oxide and mercury(II) oxide, from which he obtained magnesium amalgam (an alloy of magnesium dissolved in mercury). To obtain pure magnesium, Davy distilled the mercury from the amalgam.

**Magnesium Metallurgy** Magnesium has become increasingly important as a structural metal. Its great advantages are its low density ( $1.74 \text{ g/cm}^3$ , which compares with  $7.87 \text{ g/cm}^3$  for iron and  $2.70 \text{ g/cm}^3$  for aluminum, the other important structural metals) and the relative strength of its alloys.

Some important commercial sources of magnesium are the minerals dolomite,  $\text{CaCO}_3 \cdot \text{MgCO}_3$ , and magnesite,  $\text{MgCO}_3$ . However, magnesium ion,  $\text{Mg}^{2+}$ , is the third most abundant dissolved ion in the oceans, after  $\text{Cl}^-$  and  $\text{Na}^+$ . The oceans, therefore, are an essentially inexhaustible supply of the ion, from which the metal can be obtained. ◀

Pure magnesium metal is a relatively reactive element. Its alloys, however, contain aluminum and small quantities of other metals to impart both strength and corrosion resistance. Increasing quantities of magnesium alloy are used to make automobile and aircraft parts, as well as consumer materials such as power-tool and lawn-mower housings (Figure 21.18). Most commercial aluminum metal contains some percentage of magnesium, which improves the hardness and corrosion resistance of the aluminum.

Magnesium metal is also used as a reducing agent in the manufacture of titanium and zirconium from their tetrachlorides. (Sodium is also used as the reducing agent in the production of titanium, as we mentioned earlier.)

Zirconium metal is used to make containment vessels for uranium-235 fuel rods for nuclear power reactors, because of its low absorption of the neutrons needed in the nuclear fission of uranium-235.

**Reactions of Magnesium Metal** Once magnesium metal has been ignited, it burns vigorously in air to form the oxide.

The metal powder and fine wire burn readily. Burning magnesium metal gives off an intense white light; this is the white light you see in the burning of some fireworks and flares.

Magnesium metal is isolated from seawater by the Dow process, which is described in Section 21.2.

Perov Stanislav/Shutterstock.com

**Figure 21.18** ▲

### Magnesium in motorcycles

Magnesium alloys are used in many motorcycle parts. Shown here is a closeup of the engine area of a Harley-Davidson motorcycle. The V engine (upper right), engine block (lower right), and transmission case (lower left) are made of an aluminum–magnesium alloy.

Magnesium also burns in carbon dioxide, producing magnesium oxide and soot, or carbon (Figure 21.19).

Many fire extinguishers contain carbon dioxide, which normally smothers a fire by preventing oxygen from air getting to combustible materials. Carbon dioxide, however, cannot be used to extinguish magnesium fires; burning magnesium must be smothered with dry sand.

The pure metal reacts slowly with water. (Magnesium alloys are even less reactive.) Magnesium does react readily with steam, however.

**Magnesium Compounds** When magnesite, a magnesium carbonate mineral, is heated above 350°C, it decomposes to the oxide, a white solid:

Careful heating at low temperature results in a powdery form of the oxide that is relatively reactive. It reacts slowly with water to produce magnesium hydroxide but reacts readily with acids to yield the corresponding salts:

Large quantities of magnesium oxide are used in animal feed supplements, because magnesium ion is an important nutrient for animals. (The ion is also important for human nutrition.) Firebricks are produced by strongly heating magnesite (to about 1400°C) to give a hard, relatively inert form of magnesium oxide. Magnesium oxide is quite stable at high temperatures and is a good thermal insulator.

Magnesium hydroxide is only slightly soluble in water. (The solubility product,  $K_{sp}$ , is  $1.8 \times 10^{-11}$ .) A suspension of the white compound in water is called *milk of magnesia* (Figure 21.20). This suspension has a pH of about 10, which means the solution is mildly basic. Milk of magnesia is sold as an antacid, because the magnesium hydroxide reacts to neutralize excess hydrochloric acid in the stomach. Table 21.4 gives a summary list of the uses of compounds of magnesium and other Group 2A elements.

## Calcium

Calcium is a common element. It is present in the earth's crust as silicates, which weather to give free calcium ion,  $\text{Ca}^{2+}$ . The ion is about as abundant in seawater as magnesium ion. Calcium ion is an important nutrient for living organisms. As noted in the preceding section, seashells are principally calcium carbonate. Corals are marine organisms that grow in colonies; their calcium carbonate skeletons eventually form enormous coral reefs in warm waters. The Bahamas and the Florida Keys originated as coral reefs. Deposits of limestone (mostly  $\text{CaCO}_3$ ) formed in earlier times as sediments of seashells and coral and by the direct precipitation of calcium carbonate from seawater. Gypsum,  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ , is another important mineral of calcium; deposits originated from evaporation of inland lakes and seas.

**Calcium Metallurgy** Most calcium metal is obtained by the reduction of calcium oxide with aluminum. Calcium metal is used mainly in some alloys. For example, the addition of a small quantity of calcium to the lead used for the electrodes of lead storage batteries substantially reduces the decomposition of water into its elements during the recharging of the battery. Since gases are not produced during recharging, the battery can be sealed so it requires less maintenance.

Figure 21.19 ▲

**Reaction of magnesium and carbon dioxide** When a glowing ribbon of magnesium metal is thrust into a beaker of carbon dioxide (from the sublimation of the dry ice at the bottom of the beaker), the metal bursts into a bright flame, producing a smoke of magnesium oxide and carbon.

Figure 21.20 ▲

**Milk of magnesia** Milk of magnesia is a suspension of  $\text{Mg}(\text{OH})_2$  in water. It is used as an antacid and a laxative.

**Table 21.4** Uses of Alkaline Earth Compounds

Compound	Use
MgO	Refractory bricks (for furnaces) Animal feeds
Mg(OH) <sub>2</sub>	Source of magnesium for the metal and compounds Milk of magnesia (antacid and laxative)
MgSO <sub>4</sub> ·7H <sub>2</sub> O	Fertilizer Medicinal uses (laxative and analgesic) Mordant (used in dyeing fabrics)
CaO and Ca(OH) <sub>2</sub>	Manufacture of steel Neutralizer for chemical processing Water treatment Mortar Stack-gas scrubber (to remove H <sub>2</sub> S and SO <sub>2</sub> )
CaCO <sub>3</sub>	Paper coating and filter Antacids, dentifrices
CaSO <sub>4</sub>	Plaster, wallboard Portland cement
Ca(H <sub>2</sub> PO <sub>4</sub> ) <sub>2</sub>	Soluble phosphate fertilizer
BaSO <sub>4</sub>	Oil-well drilling mud Gastrointestinal X-ray photography Paint pigment

**Reactions of Calcium Metal** Calcium is a soft, reactive metal. It reacts with water, like the alkali metals do, to produce the metal hydroxide and hydrogen; the reaction, however, is much less vigorous.

Calcium burns in air to produce the oxide, CaO, and with chlorine to produce calcium chloride. Calcium also reacts directly with hydrogen to give the hydride. Calcium hydride, CaH<sub>2</sub>, is a convenient source of hydrogen, because it reacts easily with water to yield H<sub>2</sub>.

**Calcium Compounds** Calcium compounds are extremely important commercially (see Table 21.4). Enormous quantities of them are used in metallurgy, in building materials, in the making of glass and paper, and in other products. Limestone (CaCO<sub>3</sub>), dolomite (CaCO<sub>3</sub>·MgCO<sub>3</sub>), anhydrite (CaSO<sub>4</sub>), and gypsum (CaSO<sub>4</sub>·2H<sub>2</sub>O) are all important sources of calcium compounds. An interesting use of ground limestone is shown in Figure 21.21; this application depends on the basic character of the carbonate ion. The mineral gypsum, CaSO<sub>4</sub>·2H<sub>2</sub>O, forms plaster of Paris, CaSO<sub>4</sub>·½H<sub>2</sub>O, when heated to 100°C. Plaster of Paris is used to make wallboard.

Calcium oxide, CaO, is among the top ten industrial chemicals. It is prepared by calcining calcium carbonate. Limestone and seashells are all possible starting materials.

Calcium oxide is known commercially as *quicklime* or simply *lime*. Much of the calcium oxide produced is used in the manufacture of iron from its ores. Iron is obtained by reducing iron ore (containing iron oxides with silicate impurities) in a blast furnace. A charge of iron ore, carbon, and calcium oxide is added at the top of

Figure 21.21 ◀

**Raising the pH of a lake with ground limestone** A specially designed barge applies a slurry of finely ground limestone ( $\text{CaCO}_3$ ) to a lake to neutralize its acidity, caused by acid-rain pollution. Acid rain results from the burning of sulfur-containing materials (coal and sulfide ores) and from nitrogen oxide pollution from automobiles.

the furnace, and a stream of compressed air flows in from the bottom. The purpose of calcium oxide is to combine with silicon dioxide (sand) and silicate impurities in the iron ore to produce a glassy material (called *slag*). The slag is molten at the temperatures of the blast furnace, and it flows to the bottom of the furnace and is withdrawn. The essential reaction is that between a basic oxide (calcium oxide) and an acidic oxide (silicon dioxide).

Calcium oxide reacts exothermically with water to produce calcium hydroxide. The considerable heat released is apparent when you add a few drops of water to a pile of calcium oxide powder; there is a hiss, and puffs of steam rise from the mixture.

Commercially, calcium hydroxide is referred to as *slaked lime*. Calcium hydroxide is a strong base, and many of its uses depend on this fact. For example, hydrochloric and sulfuric acids are used to remove rust from steel products. After the steel has been cleaned this way, calcium hydroxide is used to neutralize the excess acid.

Calcium hydroxide solutions react with gaseous carbon dioxide (the acid oxide of carbonic acid) to give a white, milky precipitate of calcium carbonate.

This reaction, with its formation of a milky precipitate, is the basis of a simple test for carbon dioxide. Commercially, the reaction is important as a method of preparing precipitated calcium carbonate, a pure form of the finely divided compound. An important use of precipitated calcium carbonate is as a filler for paper. (The purpose of a filler is to improve the paper's characteristics, such as brightness and inking ability.) Precipitated calcium carbonate is also used in toothpastes, antacids, and nutritional supplements (Figure 21.22).

Bricklaying mortar is made by mixing slaked lime,  $\text{Ca}(\text{OH})_2$ , with sand and water. The mortar hardens as the mixture dries and calcium hydroxide crystallizes. Over time, however, the mortar sets to a harder solid as calcium hydroxide reacts with carbon dioxide in the air to form calcium carbonate crystals that intertwine with the sand particles. ▶

Large amounts of quicklime,  $\text{CaO}$ , and slaked lime,  $\text{Ca}(\text{OH})_2$ , are used to *soften* municipal water supplies. This may seem paradoxical at first, because the process of “softening” water refers to the removal of certain metal ions, particularly calcium

Figure 21.22 ▲

**Some antacids contain calcium carbonate** These antacid preparations consist of purified calcium carbonate with flavorings and a binder. Such antacids are sometimes prescribed as a nutrient calcium supplement.

Mortar was used by the ancient Romans for buildings and roads.

Figure 21.23 ▶

## Reaction of carbon dioxide with calcium hydroxide solution

Calcium hydroxide solution with bromthymol-blue indicator.

Carbon dioxide from dry ice reacts with calcium ion to precipitate calcium carbonate.

In an excess of carbon dioxide, the calcium carbonate dissolves to form a solution of calcium ion and hydrogen carbonate ion,  $\text{HCO}_3^-$ . In this acidic solution, bromthymol blue changes to yellow color.

ions, from the water. Water that is “hard” contains these metal ions. When soap, which is a sodium salt of a fatty acid, is added to hard water, a curdy precipitate of the calcium salt of the fatty acid forms. (When this precipitate adheres to the tub, it is called bathtub ring.) The calcium ion in hard water results when water containing carbon dioxide from air (and from rotting leaves and other organic matter) passes through limestone ( $\text{CaCO}_3$ ). The calcium carbonate dissolves in this water to produce soluble calcium hydrogen carbonate. ◀

A brief discussion of hard water and water softening appears in the essay on water at the end of Chapter 11.

Figure 21.23 illustrates the dissolution of calcium carbonate by carbon dioxide. The apparent paradox is resolved when we observe that the addition of a stoichiometric amount of calcium hydroxide to hard water containing calcium hydrogen carbonate can precipitate all of the calcium ions as calcium carbonate.

## 21.6 Group 3A and Group 4A Metals

The Group 3A elements clearly show the trend of increasing metallic character in going down any column of elements in the periodic table. Boron, at the top of Group 3A, is a metalloid, and its chemistry is typical of a nonmetal. The compound  $\text{B}(\text{OH})_3$  is actually acidic (boric acid). The rest of the elements (aluminum, gallium, indium, and thallium) are metals, but their hydroxides change from amphoteric (acidic and basic) for aluminum and gallium to basic for indium and thallium.

Bonding to boron is covalent; the atom shares its  $2s^2 2p^1$  valence electrons to give the +3 oxidation state. Although aluminum has many covalent compounds, it also has definitely ionic ones, such as  $\text{AlF}_3$ . The cation  $\text{Al}^{3+}(aq)$  is present in aqueous solutions of aluminum salts. Gallium, indium, and thallium also have ionic compounds and give cations in aqueous solution. The +3 oxidation state is the only important one for aluminum, but some +1 compounds are known for gallium and indium, and in the case of thallium, both +1 and +3 states are important.

1A	2A		3A	4A	5A	6A	7A	8A

K	Ca	Sc		In	Sn	Sb	Te	Xe
Rb	Sr	Y		Tl	Pb	Bi	Po	At
Cs	Ba	Lu						
Fr	Ra	Lr						

The Group 4A elements also show the trend of greater metallic character in going down the column of elements. The last two elements of the column, tin and lead, are well-known metals, and we will discuss them in this section. Tin and lead, in their compounds, exist in the +2 and +4 oxidation states. In tin, both oxidation states are common. In most lead compounds, lead is in the +2 oxidation state. Lead(IV) compounds, such as  $\text{PbO}_2$ , are strong oxidizing agents, indicating their tendency to revert to lead(II).

## Aluminum

Aluminum is the third most abundant element in the earth's crust (after oxygen and silicon). It occurs primarily in aluminosilicate minerals. The weathering of these rocks results in aluminum-containing clays, which are an essential part of most soils. Further weathering of clay yields bauxite, the principal ore of aluminum, which contains aluminum hydroxide,  $\text{Al}(\text{OH})_3$ , and aluminum oxide hydroxide,  $\text{AlO}(\text{OH})$ . Deposits of bauxite occur throughout the world but are particularly common in tropical and subtropical regions. Corundum is a hard mineral of aluminum oxide,  $\text{Al}_2\text{O}_3$ . The pure oxide is colorless, but the presence of impurities can give various colors to it. Sapphire (usually blue) and ruby (deep red) are gem-quality corundum (Figure 21.24).

**Aluminum Metallurgy** We discussed the details of aluminum metallurgy in Section 21.2. Aluminum is the most important commercial metal after iron. Despite the fact that pure aluminum is soft and chemically reactive, the addition of a small quantity of other metals, such as copper and magnesium, yields hard, corrosion-resistant alloys. The corrosion resistance of these alloys, together with their relatively low densities, allows their use in structural applications and for containers and packaging (Figure 21.25). Aluminum is also a very good conductor of electricity. Because of this property and its low density, aluminum is used to make electrical transmission wire.

**Reactions of Aluminum Metal** Aluminum is a chemically reactive metal, although much less reactive than the alkali metals and alkaline earth metals. It does not react at an appreciable rate with water at room temperature. In air, aluminum metal reacts readily with oxygen, but the aluminum oxide that forms gives an adherent coat, which protects the underlying metal from further reaction. (The metal will burn vigorously once started, however.) Thus, unlike iron, which is chemically less reactive than aluminum but corrodes quickly in a moist environment, aluminum is corrosion resistant. The demonstration depicted in Figure 21.26 shows that aluminum does corrode quickly in air in the absence of an oxide coating. That aluminum metal does not normally corrode, or rust, makes the metal extremely useful in many practical applications. However, this property is also the source of an environmental problem. Tin cans (nowadays mostly steel) disintegrate quickly in the environment through rusting, but aluminum cans remain intact for decades. The solution to this problem is to recycle aluminum cans, which also saves on the energy otherwise required in the electrolytic production of the metal.

Aluminum metal is also used to produce other metals. The **Goldschmidt process** is a method of preparing a metal by reduction of its oxide with powdered aluminum. Chromium metal is obtained this way; the reaction is highly exothermic, because of the large negative heat of formation of  $\text{Al}_2\text{O}_3$ :

A similar reaction with a mixture of iron(III) oxide and aluminum powder (called *thermite*) produces iron for certain kinds of welding. Once the thermite powder is ignited, the reaction is self-sustaining and gives a spectacular incandescent shower. The reaction is also the basis of certain kinds of incendiary bombs.

**Aluminum Compounds** The most important compound of aluminum is aluminum oxide,  $\text{Al}_2\text{O}_3$ , or alumina. It is prepared by heating aluminum hydroxide, obtained from

**Protective oxide coating on aluminum** In air, aluminum metal forms an adherent coating of aluminum oxide that protects the metal from further oxidation. Note the shiny surface of the foil (*left*). When a similar sheet of aluminum (*right*) is coated with mercury, however, needle-like crystals of aluminum oxide form at the aluminum–mercury surface. Instead of adhering to the metal, the aluminum oxide flakes away from the metal, and the aluminum continuously oxidizes in air.

Figure 21.27 ▲

**Heterogeneous catalysts** Many heterogeneous catalysts use aluminum oxide as a carrier, or support.

The ruby laser is described in the essay at the end of Section 7.3.

bauxite, at low temperature (550°C). Alumina is a white powder or porous solid. Although most alumina is used to make aluminum metal, large quantities are used for other purposes. For example, alumina is used as a carrier, or support, for many of the heterogeneous catalysts required in chemical processes, including those used in the production of gasoline (Figure 21.27).

When aluminum oxide is fused (melted) at high temperature (2045°C), it forms corundum, one of the hardest materials known. Corundum is used as an abrasive for grinding tools. When aluminum oxide is fused with small quantities of other metal oxides, synthetic sapphires and rubies are obtained. Synthetic ruby, for example, contains about 2.5% chromium oxide, Cr<sub>2</sub>O<sub>3</sub>. Ruby is used in fine instrument bearings (“jewel” bearings) and to make lasers. ◀

Aluminum oxide is used in the manufacture of industrial ceramics. Industrial ceramics are materials made by high-temperature firing (heating) of minerals or inorganic substances. (The term *ceramics* derives from the Greek word *kerimikos*, which means “of pottery,” referring to objects made by firing clay.) Ceramics made from aluminum oxide are used to line metallurgical furnaces, and the white ceramic material in automobile spark plugs is made from aluminum oxide. Ceramic fibers composed of aluminum oxide with other metal oxides have been developed for special applications, including ceramic-fiber-reinforced aluminum.

Aluminum sulfate octadecahydrate, Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>·18H<sub>2</sub>O, is the most common soluble salt of aluminum. It is prepared by dissolving bauxite in sulfuric acid. The salt is acidic in aqueous solution. In water, aluminum ion forms a strong hydration complex, Al(H<sub>2</sub>O)<sub>6</sub><sup>3+</sup>, and this ion in turn hydrolyzes.

Until recently, large quantities of aluminum sulfate were used to make paper. Printing paper requires the addition of materials to improve the capacity of the paper to hold ink without the ink spreading. A mixture of rosin (a tree resin) and aluminum sulfate was traditionally used for this purpose. The aluminum ion, however, makes the paper fairly acidic, and the paper fibers deteriorate over time; see Figure 21.28. Acid-free paper is now being produced that is less prone to deterioration.

Aluminum sulfate is also used to treat the wastewater obtained from the process of making paper pulp, a water slurry of fibers obtained from wood. Aluminum sulfate and a base, such as calcium hydroxide, are added to the wastewater, and a gelatinous precipitate of aluminum hydroxide forms.

Figure 21.28 ►

#### Deterioration of paper in books

Aluminum sulfate and similar acidic compounds mixed with materials such as clay and rosin were added to paper to improve its printing characteristics. However, the acids decompose the cellulose fibers in paper, causing the paper to deteriorate over time.

$\text{AlCl}_3 \cdot 6\text{H}_2\text{O}$	Antiperspirant

Colloidal particles of clay and other substances adhere to the precipitate, which is then filtered from the water. The same procedure is one of the steps in the purification of municipal water supplies. The process removes colloidal particles of clay and some bacteria.

Aluminum hydroxide is amphoteric. With acids, aluminum hydroxide acts as a base, as most metal hydroxides do. The reaction is simply a neutralization.

With bases, aluminum hydroxide forms a hydroxo ion (tetrahydroxoaluminate ion, often simply called the aluminate ion).

The amphoteric character of aluminum hydroxide is a reflection of the partial nonmetallic character of aluminum. Table 21.5 lists the major uses of aluminum compounds.

## Tin and Lead

Tin and lead were both known in ancient times. The Egyptians used lead coins and made lead sculptures perhaps as early as 5000 B.C. The use of tin in the form of bronze, an alloy of copper and tin, dates from about 3500 B.C.

Tin is a relatively rare element (ranking 50th or so in abundance in the earth's crust). However, the element occurs in localized deposits of the tin ore cassiterite ( $\text{SnO}_2$ ), so the metal is much more common than you might expect from its abundance in the earth's crust. Lead is more abundant than tin. Its most important ore is galena, a lead(II) sulfide mineral ( $\text{PbS}$ ). Galena is a common mineral and often occurs in association with other important metallic elements, such as silver.

As noted earlier, metallic character increases in moving down a group of elements. Tin, which is between the metalloid germanium and the metal lead in Group 4A, illustrates this periodic trend in a very interesting way: it has two different forms, or allotropes; one is a metal and the other is a nonmetal.

The nonmetallic form of tin, called *gray tin*, is a brittle, gray powder. The metallic form of tin is called *white tin*. White tin is stable above  $13^\circ\text{C}$ , but at lower temperatures white tin slowly undergoes a transition to gray tin.

The transition from white tin (with metallic bonding) to gray tin (with covalent bonding) becomes more rapid if the temperature is much lower than  $13^\circ\text{C}$ . During a cold winter in the 1850s, the tin pipes of some church organs in Russia and other parts of Europe began crumbling from what was described then as "tin disease." Tin disease, as we now know, is simply the transition from white to gray tin (Figure 21.29).

**Allotropes of tin** A bar of metallic tin (white tin) was cooled to  $-45^\circ\text{C}$  in a solution of tin(IV) ion catalyst. After several hours, an area of gray tin formed on the bar and then grew rapidly until the bar broke apart.

© Cengage Learning

Figure 21.30 ▲

**Tin alloys** Shown here are solder (and a soldering iron) and bronze.

**Metallurgy of Tin and Lead** Tin metal is obtained from cassiterite. Purified tin(IV) oxide,  $\text{SnO}_2$ , from tin ore is reduced to the metal by heating with carbon in a furnace.

Lead metal is obtained from ores containing galena. The ore is first concentrated in the lead(II) sulfide mineral using physical separation techniques. The concentrated ore is then roasted; that is, the sulfide ore is burned in air to yield lead(II) oxide.

The fused mass from the roasting is broken up, mixed with coke (carbon), and fed into a blast furnace. Here the lead(II) oxide is reduced with carbon monoxide produced in the blast furnace by partial oxidation of the carbon.

Tin is used to make tinfoil, which is steel (iron alloy) with a thin coat of tin. The tin coating protects the iron from corrosion from air or acidic materials. Tin cans were originally made from tinfoil, although these cans are now mostly aluminum or plastic-coated steel with perhaps a tinfoil rim. Tin is also used to make a number of alloys. Solder is a low-melting alloy of tin and lead; bronze is an alloy of copper and tin (Figure 21.30).

More than half of the lead produced is used to make electrodes for lead storage batteries. ◀ The manufacture of military and sporting ammunition also consumes a significant fraction of the lead produced. Because lead resists attack from many corrosive substances, the metal is also used to make chemical plant equipment.

**Reactions of Tin and Lead Metals** Tin and lead are much less reactive than the metals of Groups 1A, 2A, and 3A. Whereas aluminum reacts vigorously with dilute hydrochloric and sulfuric acids, tin reacts only slowly with these acids. Tin reacts more rapidly with the concentrated acids. The products are tin(II) ion and hydrogen:

Lead metal reacts with these acids, but the products  $\text{PbCl}_2$  and  $\text{PbSO}_4$  are insoluble and adhere to the metal. As a result, the reaction soon stops.

**Tin and Lead Compounds** Tin(II) chloride,  $\text{SnCl}_2$ , is used as a reducing agent in the preparation of dyes and other organic compounds. In reactions where tin(II) ion acts as a reducing agent, tin(II) ion oxidizes to tin(IV) species. Tin(II) compounds are commonly referred to as *stannous* compounds, using an older naming system. Thus, tin(II) chloride is commonly called stannous chloride. Tin also has a number of tin(IV), or *stannic*, compounds. Tin(IV) oxide,  $\text{SnO}_2$ , is, as we have seen, the chemical substance in the mineral cassiterite. Tin(IV) chloride,  $\text{SnCl}_4$ , is a liquid; it freezes at  $-33^\circ\text{C}$ . (These properties indicate that the substance is molecular, rather than ionic.)

Lead also exists in compounds in the +2 and +4 oxidation states, although lead(II) compounds are the more common. The starting compound for preparing most lead compounds is lead(II) oxide,  $\text{PbO}$ . This is a reddish yellow solid, commercially called *litharge*. Lead(II) oxide is prepared by exposing molten lead to air. Lead(IV) oxide,  $\text{PbO}_2$ , is a dark brown or black powder; it forms the cathode of lead storage batteries. The cathode is made by packing a paste of lead(II) oxide (litharge) into a lead metal grid. When the battery is charged, the lead(II) oxide is oxidized to lead(IV) oxide. Table 21.6 gives a summary list of the uses of tin and lead compounds.

Lead storage batteries are discussed in Section 19.8.

## ▶ Chemistry of the Nonmetals

The nonmetals are elements that do not exhibit the characteristics of a metal. Nearly half of them are colorless gases; and until the eighteenth century, gases were referred to as “airs” and were not well differentiated. In contrast, the special characteristics of metals held special fascination for early humans—only fire was more fascinating. And both of the two nonmetals known to the ancients, carbon and sulfur, are associated with fire.

Carbon was known in the form of charcoal and lampblack, or soot, which are products of fire. Charcoal may have been so common that it was hardly noticed at first, until its role in the reduction of metal ores was discovered. Lampblack was used by the ancient Egyptians to produce ink for writing on papyrus.

Free sulfur was less widely available than carbon, although it was probably well known because of its ready occurrence in volcanic areas. No doubt its yellow color made it stand out among other rocks. That sulfur also burned with a beautiful blue flame made it especially distinctive. The old English name of sulfur was *brimstone*, which means “a stone that burns.” This term survives today in the expression “fire and brimstone.”

These two nonmetals have rather distinctive physical characteristics, as do some of the nonmetals discovered later. For example, white phosphorus is a waxy, white solid; bromine is a reddish brown liquid; chlorine is a greenish yellow gas. Some nonmetallic elements are shown in Figure 21.31.

In the remainder of this chapter, we look at the chemistry of the nonmetals. Some questions we will address are these: What are the chemical and physical properties of the more important nonmetallic elements? What are some of the commercial uses of these substances and their compounds?

### 21.7 Hydrogen

Hydrogen is the most abundant element in the universe, comprising nearly 90% of all atoms, and is the third most abundant element on the surface of the earth. (Oxygen and silicon are the most abundant.) Most stars, including our sun, consist primarily of hydrogen. The hydrogen in our sun is the fuel for the nuclear fusion reactions that produce the life-sustaining energy that reaches our planet. On earth, the majority of hydrogen is found in oceans combined with oxygen as water. Hydrogen occurs in a variety of compounds that you have had and will have the opportunity to study as a part of your general chemistry course. These include the organic compounds (Chapter 23), biologically important compounds (Chapter 24), and acids and bases (Chapters 4 and 15).

#### Properties and Preparation of Hydrogen

Hydrogen was first isolated and identified by Henry Cavendish in 1766. His experiments consisted of reacting iron, zinc, and tin with several different binary acids. For example, H<sub>2</sub>(g) can easily be produced on a small scale according to the reaction

**Figure 21.31** ▲

Fr	Ra	Lr									

Hydrogen is a colorless, odorless gas that is less dense than air. Even though hydrogen is often placed in Group 1A of the periodic table, aside from its valence electron configuration, it has little in common with the alkali metals that make up the rest of Group 1A. It is much less likely to form a cation than any of the alkali metals, with a first ionization energy of 1312 kJ/mol versus 520 kJ/mol for lithium. Because of this, hydrogen generally combines with nonmetallic elements to form covalent compounds such as CH<sub>4</sub>, H<sub>2</sub>S, and PH<sub>3</sub>.

There are three isotopes of hydrogen: *protium*,  ${}^1_1\text{H}$  or H, which is the most abundant; *deuterium*,  ${}^2_1\text{H}$  or D; and *tritium*,  ${}^3_1\text{H}$  or T. All three isotopes are naturally occurring; however, only 0.0156% is D and a trace is T. Because an atom of D has about twice the mass of protium, compounds that contain deuterium often have different properties than those that contain only protium. For example, the normal boiling point of D<sub>2</sub>O is 101.42°C versus 100.00°C for H<sub>2</sub>O. Tritium is produced naturally in the upper atmosphere by nuclear reactions that are induced by cosmic rays or in a nuclear reactor by bombarding lithium-6 with neutrons:

Tritium is radioactive with a half-life of 12.3 years, hence very little of what is naturally produced in the upper atmosphere reaches the surface of the earth.

The isotopes of hydrogen find many applications. They are used as markers or labels that can be followed during chemical reactions. For example, a chemist who was interested in determining whether hydrogen atoms move between water molecules could make a solution that contains DOD and HOH. If hydrogen atom transfer takes place (which is the case in this example), then the solution, after a period of time, would be expected to contain DOD, HOH, and the new compound DOH. Information about the exchange rate of H with D can also be obtained from the experiment by measuring the rate at which the DOH forms. Because so many compounds contain hydrogen, the hydrogen isotopes are widely used in this manner.

The elemental form of hydrogen is a diatomic molecule having a bond dissociation energy of 432 kJ/mol. This is a large value when compared with chlorine at 240 kJ/mol. This relatively high bond dissociation energy indicates why hydrogen is less reactive than its halogen counterparts. However, with the addition of heat or light, or in the presence of a suitable catalyst, hydrogen can be induced to react.

Hydrogen is currently produced on a massive industrial scale, with an annual U.S. production on the order of 10<sup>10</sup> m<sup>3</sup>. Approximately 40% of this production is used to manufacture ammonia by the Haber process:

The hydrogen for this reaction is generally prepared using the **steam-reforming process** where steam and hydrocarbons from natural gas or petroleum react at high temperature and pressure in the presence of a catalyst to form carbon monoxide and hydrogen. For example:

Another route for hydrogen production is the *water-gas reaction*, which is no longer used commercially but may become important in the future as natural gas and petroleum become more expensive and scarce. In this reaction, steam is passed over red-hot coke or coal.

Both of these reactions produce a mixture of hydrogen and carbon monoxide. Such mixtures are used to produce various organic compounds, but to obtain pure hydrogen the carbon monoxide must be removed. First the carbon monoxide is reacted with steam in the presence of a catalyst to give carbon dioxide and more hydrogen.

The carbon dioxide is then removed by passing the mixture of gases through a basic aqueous solution.

Hydrogen can also be produced via the electrolysis of water. The net reaction is

Due to the cost of electricity, electrolysis is often not economical. However, hydrogen is produced economically as a by-product of the electrolysis of aqueous NaCl solutions during the production of NaOH and chlorine. ▶

### Hydrogen Reactions and Compounds

In addition to the preparation of ammonia, the other major use of hydrogen is in the petrochemical industry. In many cases, the reaction is one where hydrogen is added to hydrocarbon compounds containing carbon–carbon double bonds to produce compounds that contain carbon–carbon single bonds. For example, 1-butene can be reacted with hydrogen using a platinum or palladium catalyst to produce butane.

This process, called *hydrogenation*, is used in the food processing industry where oils (liquids) that contain many carbon–carbon double bonds are converted to fats (solids) that contain few or no carbon–carbon double bonds. Another important process that requires hydrogen is the cobalt-catalyzed *synthesis gas* reaction with carbon monoxide to produce methanol (vapor).

Hydrogen is also used to reduce metal oxides to extract pure metals. For example, tungsten(VI) oxide can be reduced at high temperatures via the reaction

When hydrogen combines with another element, it forms a **binary hydride**—that is, a compound that contains hydrogen and one other element. There are three categories of binary hydrides: ionic hydrides, covalent hydrides, and metallic hydrides.

*Ionic hydrides*, which contain the hydride ion,  $\text{H}^-$ , can be directly formed via the reaction of an alkali metal or the larger Group 2A metals (Ca, Sr, and Ba) with hydrogen gas near  $400^\circ\text{C}$ .

These hydrides are white crystalline compounds in which the H atoms have an oxidation state of  $-1$ . Ionic hydrides can undergo an oxidation–reduction reaction with water to produce hydrogen and a basic solution. For example:

Because of this, hydrides can be used as a source of hydrogen gas where transportation of  $\text{H}_2(g)$  is impractical, such as for inflating weather balloons. Ionic hydrides are also used as reducing agents (a source of electrons) during chemical reactions.

*Covalent hydrides* are molecular compounds in which hydrogen is covalently bonded to another element. Examples of these compounds are  $\text{NH}_3$ ,  $\text{H}_2\text{O}$ ,  $\text{H}_2\text{O}_2$ , and HF. Some of these compounds often can be formed from the direct reaction of the elements. If the nonmetal reacting with hydrogen is reactive, the reaction will readily occur without the need for elevated temperatures or a catalyst:

The reaction of hydrogen with oxygen to form water is an example of a reaction that requires the input of energy to get started; however, once it does, the reaction is rapid and exothermic.

See Section 19.10 for a discussion of the electrolysis of sodium chloride solutions.

## 21.8 Group 4A: The Carbon Family

The elements of Group 4A show in more striking fashion than the previous groups the normal periodic trend of greater metallic character going down a column. Carbon, the first element in the group, is distinctly nonmetallic. Silicon and germanium are metalloids, or semimetals, although their chemical properties are primarily those of nonmetals. Tin and lead, the last two elements in the group, are metals.

In the following subsections, we will look at carbon and silicon. Both elements have many important compounds that exhibit tetrahedral ( $sp^3$ ) bonding. Carbon, however, also has many compounds that contain multiple bonds in which  $sp$  and  $sp^2$  bonding occurs; silicon has very few such compounds. Another difference in the bonding characteristics of these elements is silicon's ability to form compounds exhibiting octahedral bonding, which is not seen with carbon. The hexafluorosilicate ion,  $\text{SiF}_6^{2-}$ , is an example of such bonding.

### Carbon

One of the most important features of the carbon atom is its ability to bond to other carbon atoms to form chains and rings of enormous variety. *The covalent bonding of two or more atoms of the same element to one another* is referred to as **catenation**. Although other elements display catenation, none show it to the same degree as carbon. Millions of carbon compounds are known, most classified as *organic*. These can be thought of as derivatives of hydrocarbons, each consisting of a chain (or more complicated arrangement) of carbon atoms to which hydrogen atoms are bonded. In this section, we will confine ourselves to the element and its oxides and carbonates.

**Allotropes of Carbon** Until recently, carbon was thought to occur in only two principal allotropic forms: diamond and graphite. Both allotropes are covalent network solids, whose structures we discussed in detail in Section 11.8. In diamond, each carbon atom is tetrahedrally ( $sp^3$ ) bonded to four other carbon atoms. To move one plane of atoms in the diamond crystal relative to another requires the breaking of many strong carbon–carbon bonds. Because of this, diamond is one of the hardest substances known. As a pure substance, diamond is colorless, although natural diamond may be colored by impurities.

Graphite is a black substance having a layer structure. Each layer consists of carbon atoms bonded to three other carbon atoms to give a hexagonal pattern of carbon atoms arranged in a plane. The bonding involves  $sp^2$  hybridization of the carbon atoms with delocalized  $\pi$  electrons. You can also describe the bonding in terms of resonance formulas with alternating single and double bonds. One layer of carbon atoms in graphite is held to another layer only by van der Waals forces.

Unlike diamond, graphite is a good electrical conductor, because of the delocalized bonding within layers. The layer structure of graphite also explains its lubricating properties. At one time, this was explained as a simple sliding of one

Because it is such an exothermic reaction and the product is a gas, it is an ideal rocket fuel (Figure 21.32).

The combustion of hydrogen produces more heat per gram than any other fuel (120 kJ/g). Unlike hydrocarbons, it is a “clean fuel” because the product (water) is environmentally benign. Because of these features, hydrogen may become the favorite automobile fuel of the twenty-first century. (An energy source is needed to produce the hydrogen, however.)

*Metallic hydrides* are compounds containing a transition metal and hydrogen. Generally, the formula of these compounds is  $\text{MH}_x$ , where  $x$  is often not an integer. These compounds contain hydrogen atoms that are spread throughout a metal crystal occupying the holes in the crystal lattice. Often, hydrogen atoms enter the holes in nonstoichiometric amounts. The result is that the composition of the metallic hydride is variable. For example, under one pressure of  $\text{H}_2$  the composition of the metallic hydride  $\text{MH}_x$  might be  $\text{MH}_{0.4}$ , whereas at a higher pressure of  $\text{H}_2$  it might be  $\text{MH}_{0.5}$ . Examples of these compounds are  $\text{TiH}_{1.7}$  and  $\text{ZrH}_{1.9}$ .

layer over another. It has been shown, however, that graphite is not a good lubricant in a vacuum. Moist air appears to be necessary for this lubricating property. The adsorption of water molecules to the graphite layers appears to break the van der Waals attraction between layers, allowing them to slide easily over one another. In a vacuum, the collective van der Waals attractions are sufficient to prevent easy sliding of one layer over the other.

In 1985, a third allotropic form of carbon, known as buckminsterfullerene ( $C_{60}$ ), was discovered. This molecular allotrope has a stable “soccer-ball” structure, described in the essay at the end of this section. Since the discovery of buckminsterfullerene, though, a series of similar spherical carbon molecules have been discovered, in addition to tubeshaped molecules. Then in 2004, Andre Geim and Konstantin Novoselov reported that they were able to prepare single-layer sheets of graphite, called graphene. Together, there are now many allotropic forms of carbon known.

**Carbon Black** The form of carbon known as *carbon black* is composed of extremely small crystals of carbon having an amorphous, or imperfect, graphite structure. It is produced in large quantities by burning natural gas ( $CH_4$ ) or petroleum hydrocarbons in a limited supply of air so that heat “cracks” (or breaks bonds in) the hydrocarbon. Lampblack is a form of carbon black.

Carbon black is used in the manufacture of rubber tires (to increase wear) and as a pigment in black printing inks. Coke is an amorphous carbon obtained by heating coal in the absence of air; it is used in large quantities in the making of iron.

**Oxides of Carbon** Carbon has two principal oxides: carbon monoxide,  $CO$ , and carbon dioxide,  $CO_2$ . Carbon and organic compounds burn in an excess of oxygen to give carbon dioxide,  $CO_2$ . However, an equilibrium exists among carbon, carbon monoxide, and carbon dioxide that favors carbon monoxide above  $700^\circ C$ .

For this reason, carbon monoxide is almost always one of the products of combustion of carbon and organic compounds, unless an excess of oxygen is present, in which case the carbon monoxide burns to carbon dioxide.

These two oxides of carbon are quite different in their chemical and physiological properties. Carbon monoxide is a colorless, odorless gas that burns in air with a blue flame. It is a toxic gas, which poisons by attaching strongly to iron atoms in the hemoglobin of red blood cells, preventing them from carrying out their normal oxygen-carrying function. As a result, the cells of the body become starved for oxygen.

Carbon monoxide is manufactured industrially from natural gas ( $CH_4$ ) and petroleum hydrocarbons, either by reaction with steam or by partial oxidation. For example,

The product in these reactions is a mixture of carbon monoxide and hydrogen, which is called *synthesis gas*. Synthesis gas can yield any of a number of organic products depending on the reaction conditions and catalyst. Methanol,  $CH_3OH$ , for example, is produced in large quantities from synthesis gas.

Carbon dioxide is a colorless, odorless gas with a faint acid taste. Under normal circumstances, the gas is nontoxic, although at high concentrations it interferes with respiration. Carbon dioxide does not support most combustions, which makes  $CO_2$  useful as a fire extinguisher.

© Cengage Learning

**Figure 21.33** ▲

**Test for carbon dioxide** When carbon dioxide is bubbled into a solution of calcium hydroxide (limewater), a milky white precipitate of calcium carbonate forms. This is the basis of a test for carbon dioxide. The reaction is also used to manufacture pure calcium carbonate. (The needle at the right is to provide an escape for excess gas.)

Carbon dioxide is produced whenever carbon or organic materials are burned. For example,

Carbon dioxide is obtained commercially as a by-product in the production of ammonia (see Section 21.9) and in the calcining (strong heating) of limestone to give calcium oxide. Liquid carbon dioxide and solid carbon dioxide (dry ice) are used in large quantities as refrigerants. Carbonated beverages are made by dissolving carbon dioxide gas under pressure in an aqueous solution of sugar and flavorings. Carbonated water is acidic as the result of the formation of carbonic acid, although carbonated beverages frequently also contain fruit acids and phosphoric acid.

**Carbonates** Carbon dioxide dissolves in water to form an aqueous solution of carbonic acid.

The acid is diprotic (has two acidic H atoms per molecule) and dissociates to form hydrogen carbonate ion and carbonate ion.

Carbonic acid has never been isolated from solution, but its salts, hydrogen carbonates and carbonates, are well known. When you bubble carbon dioxide gas into an aqueous solution of calcium hydroxide, a milky white precipitate of calcium carbonate forms (Figure 21.33).

This is a standard test for carbon dioxide. The reaction is also used to manufacture a pure calcium carbonate for antacids and other products.

Carbonate minerals are very common and many are of commercial importance. Limestone contains the mineral calcite, which is calcium carbonate,  $\text{CaCO}_3$ . Much of this was formed by marine organisms, although some limestone was also formed by direct precipitation from water solution.

Table 21.7 lists uses of some compounds of carbon (and of silicon, discussed in the next subsection).

**Table 21.7** Uses of Some Compounds of Carbon and of Silicon

Compound	Use
CO	Fuel; reducing agent Synthesis of methanol, $\text{CH}_3\text{OH}$
$\text{CO}_2$	Refrigerant Carbonation of beverages
$\text{SiO}_2$	Source of silicon and its compounds Abrasives Glass
$(\text{CH}_3)_2\text{SiCl}_2$	Manufacture of silicones (used as lubricants, hydraulic fluids, caulking compounds, and medical implants)

## Silicon

If we were to list the materials of technology, silicon would certainly be prominent on that list. Silicon is the basic material in the semiconductor devices that make up smartphones, computers, and other electronics gear. Oxygen compounds of silicon also are important to technology. Quartz crystals, a form of silica (also called silicon dioxide,  $\text{SiO}_2$ ), for example, are used to control frequencies in radio transmitters and watches. And many practical materials such as cement and bricks are silicate materials. Silicates are compounds of silicon and oxygen with one or more metallic elements.

Silicon occurs in the earth's crust, the outermost solid layer of the planet, as compounds with oxygen. About 95% of the earth's crust is silica and silicate rocks and minerals. Elemental silicon is obtained by reducing quartz sand ( $\text{SiO}_2$ ) with coke (C) in an electric furnace at  $3000^\circ\text{C}$ .

Silicon has a diamond-like structure (in which silicon atoms bond tetrahedrally to four other silicon atoms). It is a hard, lustrous gray solid and is used to make alloys and solid-state electronic devices.

For the manufacture of solid-state devices, it is necessary to start with extremely pure silicon (no more than  $10^{-8}\%$  impurities). See Figure 21.34. You first convert the impure element to silicon tetrachloride,  $\text{SiCl}_4$ , which is a low-boiling liquid (b.p.  $58^\circ\text{C}$ ) that can be purified by distillation.

You then reduce the purified silicon tetrachloride by passing the vapor with hydrogen through a hot tube, where pure silicon crystallizes on the surface of a pure silicon rod.

**Silica (Silicon Dioxide)** Silica (whose formal chemical name is silicon dioxide,  $\text{SiO}_2$ ) has several different crystalline forms. The most important of these is quartz, which is a constituent of many rocks. It is the weathering of these rocks that releases quartz particles, a major component of most kinds of sands. Amethyst is a gem form of quartz; it contains a small quantity of  $\text{Fe}_2\text{O}_3$ , which is believed to be responsible for its purple color. **Silica**,  $\text{SiO}_2$ , is a covalent network solid in which each silicon atom is covalently bonded in tetrahedral directions to four oxygen atoms; each oxygen atom is in turn bonded to another silicon atom (Figure 21.35).

Quartz crystals have a very interesting and useful property: they exhibit the *piezoelectric effect*. In a piezoelectric crystal, such as quartz, compression of the crystal in a particular direction causes an electric voltage to develop across it. Such crystals are used in phonograph pickups and microphones to convert sound vibrations to alternating electric currents. The opposite effect is also possible: an alternating

© Karukai/Shutterstock.com

electric current applied to a piezoelectric crystal can make it vibrate. When cut to precise dimensions, the crystal responds most strongly to a certain vibrational frequency. Such crystals are used to control the frequency of an alternating electric current. When the alternating current frequency deviates from the natural frequency of the crystal, a feedback mechanism adjusts the alternating current frequency. Quartz crystals are used to control radio and television frequencies, as well as clocks.

**Silicates** A **silicate** is a compound of silicon and oxygen (with one or more metals) that may be formally regarded as a derivative of silicic acid,  $H_4SiO_4$  or  $Si(OH)_4$ . Silicic acid has never been isolated, although solutions containing anions of the acid are well known. When silica is melted with sodium carbonate, it forms a soluble material referred to commercially as *water glass*. These solutions contain various silicate ions, such as

The solution also contains ions with two or more silicon atoms, which form by condensation reactions. A **condensation reaction** is a reaction in which two molecules or ions are chemically joined by the elimination of a small molecule such as  $H_2O$ . For example, the silicic acid anion can react in a condensation reaction with another such anion to form a disilicate anion (anion of two silicon atoms):

Silicate anions containing long  $\text{Si}-\text{O}-\text{Si}-\dots$  chains can result from such condensation reactions. Materials exhibiting chains and networks of this sort of silicon-oxygen bonding are common. The silicate minerals of the earth all have this type of structure. (See Figure 21.36.)

**Silicones** A **silicone** is a polymer containing chains of silicon-oxygen bonds, with hydrocarbon groups (such as  $\text{CH}_3-$ ) attached to silicon atoms. (Polymers are very large molecules made up of smaller molecules repeatedly linked together. See Section 2.6.) The preparation of many silicones begins with the reaction of silicon with methyl chloride at elevated temperature in the presence of a copper catalyst.

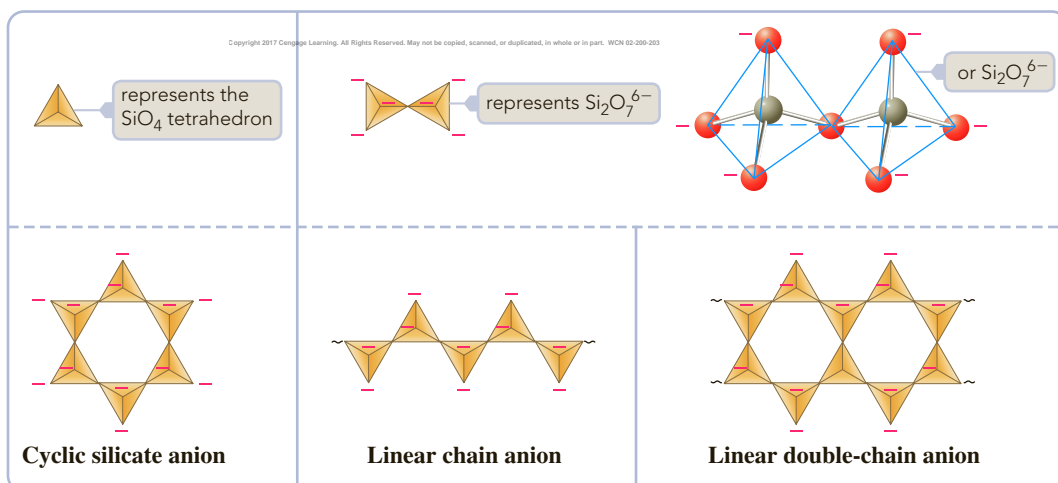

Figure 21.36 ►

**Structures of some silicate minerals** A number of silicate minerals consist of finite silicate anions, such as  $\text{SiO}_4^{4-}$  and  $\text{Si}_2\text{O}_7^{6-}$ . Beryl contains the cyclic anion  $\text{Si}_6\text{O}_{18}^{12-}$ . Other silicate minerals have anions with very long chains or double chains.

If a long chain of Si—O bonds is desired, the product of this reaction is reacted with water.

The silicon-containing product of this reaction then undergoes a condensation reaction to form a silicone oil (polydimethylsiloxane) and water. (See Figure 21.37.)

Depending on the application for the silicone, the chain length can be varied to make oils of different weights, or the chains can be linked together to form *elastomers* (rubbers). The methyl group,  $\text{CH}_3$ , can also be replaced by a different organic group, which can lead to the formation of hard materials called resins. Silicones have a wide variety of applications (Figure 21.38).

Figure 21.37 ▲

**Molecular model of a silicone** This model shows a fragment of the polydimethylsiloxane molecule. Note how the chain structure is created by linking  $(\text{CH}_3)_2\text{SiO}_2$  tetrahedra through Si—O bonds.

## 21.9 Group 5A: Nitrogen and the Phosphorus Family

Like the carbon family of elements, the Group 5A elements show the distinct trend of increasing metallic character as you go from top to bottom of the column. The first members, nitrogen and phosphorus, are nonmetallic; arsenic and antimony are metalloids; bismuth is a metal.

As expected for a second-period element, nitrogen is in many respects different from the other elements in its group. You can see this in the formulas of the elements and compounds. Elementary nitrogen is  $\text{N}_2$ , while white phosphorus is  $\text{P}_4$ . Similarly, the common +5 oxoacid of nitrogen is  $\text{HNO}_3$ , that of phosphorus is  $\text{H}_3\text{PO}_4$ , and that of arsenic is  $\text{H}_3\text{AsO}_4$ . (Nitrogen exists in many molecular compounds in a variety of oxidation states. Phosphorus exists in many compounds in the +5 and +3 oxidation states. Many phosphorus compounds have P—O—P bonding.)

### Nitrogen

The element nitrogen is crucial to life: it is a component of all proteins, which are involved in almost every biochemical process that occurs in living organisms. Most of the available nitrogen on earth, however, is present as nitrogen gas (dinitrogen,  $\text{N}_2$ ) in the atmosphere, which consists of 78.1%  $\text{N}_2$ , by mass. Dinitrogen, also simply called “nitrogen,” has collected in the atmosphere because of its relative chemical unreactivity. Most organisms cannot use dinitrogen from the atmosphere as their source of the element. However, certain soil bacteria, as well as bacteria that live in nodules on the roots of beans, clover, and similar plants, can “fix” nitrogen; that is, they convert dinitrogen to ammonium and nitrate compounds. Plants use these simple nitrogen compounds to make proteins and other complex nitrogen compounds. Animals eat these plants, and other animals eat those animals. Finally, bacteria in decaying organic matter convert the nitrogen compounds back to dinitrogen. In this way, nitrogen in our environment continually cycles from dinitrogen to living organisms and back. Figure 21.40 depicts this *nitrogen cycle*.

**Properties and Uses of Nitrogen** Daniel Rutherford, a chemist and physician, discovered nitrogen,  $\text{N}_2$ , in air in 1772. In his experiments, he removed the oxygen from air by burning a substance in it. When burning carbon-containing substances, he removed the carbon dioxide that formed by reacting it with aqueous potassium hydroxide. He then showed that the residual gas would no longer support either combustion or living organisms. Although this residual gas is mostly  $\text{N}_2$ , it does contain small amounts of noble gases.

## Materials

A CHEMIST Looks at . . .

# Buckminsterfullerene— A Molecular Form of Carbon

Until recently, carbon was thought to occur in only two principal forms: diamond and graphite, both network solids. In 1985, Harold W. Kroto (from the University of Sussex in Brighton, England) approached Richard E. Smalley and Robert F. Curl (at Rice University, in Houston, Texas) to do some experiments to simulate the conditions in certain stars to see what sorts of carbon-containing molecules might be produced. The research group at Rice had previously constructed an instrument in which they used an intense laser beam to vaporize solids. The hot vapor produced in this way could then be directed as a molecular beam into a mass spectrometer, where the molecular weight of the species in the vapor could be measured.

The experiments on the vaporization of graphite produced surprising results. Molecular clusters of 2 to 30 carbon atoms were found, as expected; but in addition, the mass spectrum of the vapor consistently showed the presence of a particularly abundant molecule,  $C_{60}$ . Why was this molecule so stable? Kroto, Smalley, and Curl wrestled with this problem and eventually came to the conclusion that the molecule must be like a piece of graphite sheet that somehow closed back on itself to form a closed-dome structure. Kroto recalled how he once built a cardboard dome with the night sky printed on it for his children; he thought it contained not only hexagons, as in graphite, but also pentagons. Smalley set about trying to construct a model of  $C_{60}$  by gluing paper polygons together. He discovered that he could obtain a very stable, closed polygon with 60 vertices by starting with a pentagon and attaching hexagons to each of its five edges. To this bowl-shaped structure he attached more pentagons and hexagons, producing a paper soccer ball stable enough to bounce on the floor. The molecular structure is shown in Figure 21.39. Kroto and Smalley named the molecule buckminsterfullerene, after R. Buckminster Fuller, who studied closed-dome architectural structures constructed from polygons.

In 1990, buckminsterfullerene was prepared in gram quantities. Once the reddish brown substance was available in sufficient quantity, researchers were able to verify the soccer-ball structure of the  $C_{60}$  molecule. Since the discovery of buckminsterfullerene, many similar molecular forms of carbon, called fullerenes, have been found and studied.

In 1996, the Nobel Prize in chemistry was awarded to professors Curl, Kroto, and Smalley for their discovery.

Figure 21.39 ▲

**Structure of buckminsterfullerene** *Top:* A molecular model of  $C_{60}$ . Carbon atoms are at the corners of each polygon. Each bond is intermediate between a single and a double bond, similar to the bonding in graphite. *Bottom:* The buckminsterfullerene molecule is often called a “buckyball,” because of its soccer-ball appearance.

■ See Problems 21.193 and 21.194.

Nitrogen,  $N_2$ , is a relatively unreactive element because of the stability of the nitrogen–nitrogen triple bond. (The  $N\equiv N$  bond energy is 945 kJ/mol, compared with 163 kJ/mol for the  $N-N$  bond energy.) When substances burn in air, they generally react with oxygen, leaving the nitrogen unreacted. Some very reactive

**Figure 21.40** ◀

**The nitrogen cycle** Nitrogen,  $N_2$ , is fixed (converted to compounds) by bacteria, by lightning, and by the industrial synthesis of ammonia. Fixed nitrogen is used by plants and enters the food chain of animals. Later, plant and animal wastes decompose. Denitrifying bacteria complete the cycle by producing free nitrogen again.

metals do react directly with nitrogen, however. For example, when magnesium metal burns in air, it forms the nitride, as well as the oxide.

Because the nitride ion,  $N^{3-}$ , is a very strong base, ionic nitrides react with water, producing ammonia.

Magnesium nitride reacts with water to give magnesium hydroxide and ammonia.

Air is the major commercial source of nitrogen. The components of air are separated by liquefaction, followed by distillation. Nitrogen is the most volatile component in liquid air, so it is the first to distill off, leaving behind a liquid that is primarily oxygen with a small amount of noble gases (mostly argon).

Liquid nitrogen is used as a refrigerant to freeze foods, to freeze soft or rubbery materials prior to grinding them, and to freeze biological materials (Figure 21.41). Large quantities of nitrogen are also used as a *blanketing gas*, whose purpose is to protect a material from oxygen during processing or storage. Thus, electronic components are often made under a nitrogen atmosphere. The other principal use of nitrogen is to prepare nitrogen compounds.

**Nitrogen Compounds** Ammonia,  $NH_3$ , is the most important commercial compound of nitrogen. A colorless gas with a characteristic irritating or pungent odor, it is prepared commercially from  $N_2$  and  $H_2$  by the *Haber process*. Figure 21.42 shows a flowchart of the industrial preparation of ammonia from natural gas, steam, and air. Small amounts can be prepared in the laboratory by heating a solution of an ammonium salt with a strong base, such as  $NaOH$  or  $Ca(OH)_2$  (Figure 21.43).

Charles D Winters/Getty Images

**Figure 21.41** ▲

**Liquid nitrogen** When liquid nitrogen is poured over a balloon on a table (which, although at room temperature, is about  $220^\circ$  above the boiling point of nitrogen), the liquid sizzles and boils away violently, creating a fog by cooling water vapor from the surrounding air.

Figure 21.42 ▲

**Industrial preparation of ammonia (flowchart)** The raw materials are natural gas, water, and air. Hydrogen for the Haber process is obtained by reacting natural gas with steam to give carbon monoxide and hydrogen. In the next step, carbon monoxide is reacted with steam to give carbon dioxide and additional hydrogen. The carbon dioxide is removed by dissolving it in water solution.

Ammonia is easily liquefied, and the liquid is used as a nitrogen fertilizer. Ammonium salts, such as the sulfate and nitrate, are also sold as fertilizers. Large quantities of ammonia are converted to urea,  $\text{NH}_2\text{CONH}_2$ , which is used as a fertilizer, as a livestock feed supplement, and in the manufacture of urea–formaldehyde plastics. Ammonia is also the starting compound for the preparation of most other nitrogen compounds.

Dinitrogen monoxide, commonly known as nitrous oxide,  $\text{N}_2\text{O}$ , is a colorless gas with a sweet odor. It can be prepared by careful heating of molten ammonium nitrate. (If heated strongly, it explodes.)

Nitrous oxide, or laughing gas, is used as a dental anesthetic. It is also useful as a propellant in whipped-cream dispensers. The gas dissolves in cream under pressure. When the cream is dispensed, the gas bubbles out, forming a foam.

Nitrogen monoxide, commonly known as nitric oxide,  $\text{NO}$ , is a colorless gas that is of great industrial and biological importance. ◀ Although it can be prepared by the direct combination of the elements at elevated temperatures, large amounts are prepared from ammonia as the first step in the commercial preparation of nitric acid. The ammonia is oxidized in the presence of a platinum catalyst.

Nitric acid,  $\text{HNO}_3$ , is the third most important industrial acid (after sulfuric and phosphoric acids). It is used to prepare explosives, nylon, and polyurethane plastics. Nitric acid is produced commercially by the **Ostwald process**, which is an industrial preparation of nitric acid starting from the catalytic oxidation of ammonia to nitrogen monoxide. In this process, ammonia is burned in the presence of a platinum catalyst to give  $\text{NO}$ , which is then reacted with oxygen to form  $\text{NO}_2$ . The  $\text{NO}_2$  is dissolved in water, where it reacts to form nitric acid and nitrogen monoxide.

The nitrogen monoxide produced in the last step is recycled for use in the second step.

Figure 21.43 ▲

**Preparation of ammonia from an ammonium salt** Sodium hydroxide solution was added to ammonium chloride. Ammonia gas, formed in the reaction, turns colorless phenolphthalein in the moist paper to a bright pink.

The biological importance of  $\text{NO}$  was discussed in an essay in Chapter 5.

Figure 21.44 ◀

Reaction of copper metal with dilute nitric acid

Nitric acid is a strong oxidizing agent. Although copper metal is unreactive to most acids, it is oxidized by the nitrate ion in acid solution. In dilute acid, nitrogen monoxide is the principal reduction product (Figure 21.44).

With concentrated nitric acid, nitrogen dioxide is obtained (Figure 21.45).

When certain nitrates, such as sodium nitrate, are heated, they decompose to the nitrites.

The corresponding acid, nitrous acid, is unstable and is usually prepared when needed as an aqueous solution. When the stoichiometric amount of sulfuric acid is added to an aqueous solution of barium nitrite,  $\text{Ba}(\text{NO}_2)_2$ , barium sulfate precipitates, leaving a solution of nitrous acid.

Table 21.8 lists uses of some compounds of nitrogen (and of phosphorus, discussed in the next section).

Figure 21.45 ▲

Reaction of copper metal with concentrated nitric acid The principal reduction product from concentrated nitric acid is nitrogen dioxide,  $\text{NO}_2$  (reddish brown gas).

### CONCEPT CHECK 21.1

Considering the fact that  $\text{N}_2$  makes up about 80% of the atmosphere, why don't animals use the abundant  $\text{N}_2$  instead of  $\text{O}_2$  for biological reactions?

## Phosphorus

Phosphorus, the most abundant of the Group 5A elements, occurs in phosphate minerals, such as fluorapatite, whose formula is written either  $\text{Ca}_5(\text{PO}_4)_3\text{F}$  or  $3\text{Ca}_3(\text{PO}_4)_2 \cdot \text{CaF}_2$ . Unlike nitrogen, which exists in important compounds with oxidation states between  $-3$  and  $+5$ , the most important oxidation states of phosphorus are  $+3$  and  $+5$ . Like nitrogen, however, phosphorus is an important element in living organisms. DNA (deoxyribonucleic acid), a chainlike biological molecule in which information about inheritable traits resides, contains

**Table 21.8** Uses of Some Compounds of Nitrogen and of Phosphorus

Compound	Use
$\text{NH}_3$	Nitrogen fertilizer Manufacture of nitrogen compounds
$\text{N}_2\text{H}_4$	Blowing agent for foamed plastics Water treatment
$\text{HNO}_3$	Explosives Polyurethane plastics
$\text{Ca}(\text{H}_2\text{PO}_4)_2 \cdot \text{H}_2\text{O}$	Phosphate fertilizer Baking powder
$\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$	Animal feed additive Toothpowder
$\text{H}_3\text{PO}_4$	Manufacture of phosphate fertilizers Soft drinks
$\text{PCl}_3$	Manufacture of $\text{POCl}_3$ Manufacture of pesticides
$\text{POCl}_3$	Manufacture of plasticizers (substances that keep plastics pliable) Manufacture of flame retardants
$\text{Na}_5\text{P}_3\text{O}_{10}$	Detergent additive

phosphate groups along the length of its chain. Similarly, ATP (adenosine triphosphate), the energy-containing molecule of living organisms, contains phosphate groups.

**Allotropes of Phosphorus** Phosphorus has two common allotropes: white phosphorus and red phosphorus (Figure 21.46). White phosphorus, a waxy, white solid, is very poisonous and very reactive. If white phosphorus is left exposed to air, it bursts spontaneously into flame. Because of its reactivity with oxygen, white phosphorus is stored under water, in which it is insoluble. As you might expect from its low melting point ( $44^\circ\text{C}$ ), white phosphorus is a molecular solid, with the formula  $\text{P}_4$ .

The phosphorus atoms in the  $\text{P}_4$  molecule are arranged at the corners of a regular tetrahedron such that each atom is single-bonded to the other three (Figure 21.47). The experimentally determined  $\text{P}-\text{P}-\text{P}$  bond angle is  $60^\circ$ . Because this is considerably smaller than the normal bond angle, the bonding in  $\text{P}_4$  is strained and therefore weaker. This accounts for the reactivity seen in this phosphorus allotrope; chemical reactions of  $\text{P}_4$  replace its weak bonds by stronger ones.

**Figure 21.46** ▶**Allotropes of phosphorus***Left:* White phosphorus.*Right:* Red phosphorus.

White phosphorus is a major industrial chemical and is prepared by heating phosphate rock with coke (C) and quartz sand ( $\text{SiO}_2$ ) in an electric furnace. The overall reaction is

The gases from the furnace are cooled by water to condense the phosphorus vapor to the liquid; the carbon monoxide gas is used as a fuel. The other product, calcium silicate glass (called *slag*), is drained periodically from the bottom of the furnace.

Most of the white phosphorus produced is used to manufacture phosphoric acid,  $\text{H}_3\text{PO}_4$ . Some white phosphorus is converted to red phosphorus, an amorphous material that can be crystallized to give an allotrope with a polymeric chain structure (Figure 21.48). Red phosphorus is much less reactive than white phosphorus and can be stored in the presence of air. This phosphorus allotrope is relatively nontoxic and is used in the striking surface for safety matches. Red phosphorus is made by heating white phosphorus at about  $400^\circ\text{C}$  for several hours.

**Phosphorus Oxides** Phosphorus has two common oxides, tetraphosphorus hexoxide,  $\text{P}_4\text{O}_6$ , and tetraphosphorus decoxide,  $\text{P}_4\text{O}_{10}$ . Their common names are phosphorus trioxide and phosphorus pentoxide, respectively. The names are at odds with present rules of nomenclature but stem from their empirical formulas,  $\text{P}_2\text{O}_3$  and  $\text{P}_2\text{O}_5$ .

These oxides have interesting structures (Figure 21.49). Tetraphosphorus hexoxide has a tetrahedron of phosphorus atoms, as in  $\text{P}_4$ , but with oxygen atoms between each pair of phosphorus atoms. Tetraphosphorus decoxide is similar, except that each phosphorus atom has an additional oxygen atom bonded to it. These phosphorus–oxygen bonds are much shorter than the ones in the  $\text{P—O—P}$  bridges (139 pm versus 162 pm); hence, they are best represented as double bonds.

Tetraphosphorus hexoxide is a low-melting solid (m.p.  $23^\circ\text{C}$ ) and the anhydride of phosphorous acid,  $\text{H}_3\text{PO}_3$ . Tetraphosphorus decoxide is the most important oxide; it is a white solid that sublimates at  $360^\circ\text{C}$ . This oxide is the anhydride of

Figure 21.47 ▲

**Structure of the  $\text{P}_4$  molecule**

The structure is obtained by linking  $\text{P}_4$  tetrahedra together after breaking a bond in each tetrahedron.

Figure 21.49 ▲

**Structures of the phosphorus oxides** *Left:* The phosphorus atoms in  $\text{P}_4\text{O}_6$  have tetrahedral positions, as in  $\text{P}_4$ ; however, the phosphorus atoms are bonded to oxygen atoms, forming  $\text{P—O—P}$  bridges between each pair of phosphorus atoms. *Right:* The  $\text{P}_4\text{O}_{10}$  molecule is similar, except that an additional oxygen atom is bonded to each phosphorus atom. Both ball-and-stick and space-filling models are shown.

phosphoric acid,  $\text{H}_3\text{PO}_4$ . The reaction with water is quite vigorous, making tetraphosphorus decoxide useful in the laboratory as a drying agent. It is prepared by burning white phosphorus in air.

Tetraphosphorus decoxide is used to manufacture phosphoric acid, an oxoacid.

**Oxoacids of Phosphorus** Phosphorus has many oxoacids, but the most important of these can be thought of as derivatives of orthophosphoric acid (often called simply phosphoric acid),  $\text{H}_3\text{PO}_4$ . Orthophosphoric acid is a colorless solid, melting at  $42^\circ\text{C}$  when pure. It is usually sold as an aqueous solution, however. Orthophosphoric acid is triprotic (three acidic H atoms per molecule); possible sodium salts are sodium dihydrogen phosphate ( $\text{NaH}_2\text{PO}_4$ ), disodium hydrogen phosphate ( $\text{Na}_2\text{HPO}_4$ ), and trisodium phosphate ( $\text{Na}_3\text{PO}_4$ ). The acid has the following electron-dot formula:

Orthophosphoric acid is produced in enormous quantity either directly from phosphate rock or from tetraphosphorus decoxide, which in turn is obtained by burning white phosphorus. In the direct process, phosphate rock is treated with sulfuric acid, from which a solution of phosphoric acid is obtained by filtering off the calcium sulfate and other solid materials. The product is an impure phosphoric acid, which is used in the manufacture of phosphate fertilizers. ◀

A purer grade of orthophosphoric acid is obtained by reacting tetraphosphorus decoxide with water. It is used in soft drinks for tartness.

Orthophosphoric acid,  $\text{H}_3\text{PO}_4$ , undergoes condensation reactions to form other phosphoric acids. For example, two orthophosphoric acid molecules condense to form diphosphoric acid (also called pyrophosphoric acid).

Two series of these phosphoric acids exist (all having phosphorus in the +5 oxidation state). One series consists of the linear **polyphosphoric acids**, which are *acids with the general formula  $\text{H}_{n+2}\text{P}_n\text{O}_{3n+1}$ , formed from linear chains of P—O bonds.*

The other series consists of the **metaphosphoric acids**, which are *acids with the general formula  $(\text{HPO}_3)_n$* . Figure 21.50 shows the structure of a cyclic, or ring, metaphosphate anion. When a linear polyphosphoric acid chain is very long, the formula becomes  $(\text{HPO}_3)_n$ , with  $n$  very large, and the acid is called *polymetaphosphoric acid*.

Because phosphate rock contains  $\text{CaF}_2$ , hydrofluoric acid is a by-product in the preparation of phosphoric acid. HF is used in aluminum production.

**Figure 21.50** ▲

**The structure of trimetaphosphate ion,  $\text{P}_3\text{O}_9^{3-}$**  A cyclic metaphosphate ion; the general formula of the metaphosphate ions is  $(\text{PO}_3^-)_n$ .

The polyphosphates and metaphosphates have been used in detergents, where they act as water softeners by complexing with metal ions in the water. Sodium triphosphate,  $\text{Na}_5\text{P}_3\text{O}_{10}$ , one of the most commonly used polyphosphates, is manufactured by adding sufficient sodium carbonate to orthophosphoric acid to give a solution of the salts  $\text{NaH}_2\text{PO}_4$  and  $\text{Na}_2\text{HPO}_4$ . When this solution is sprayed into a hot kiln, the orthophosphate ions condense to give sodium triphosphate.

The use of phosphates in detergents has been criticized for contributing to the overfertilization of plants and algae in lakes (a process referred to as *eutrophication*). Such lakes become oxygen-deficient from decomposing plants and algae, and the fish die. The use of phosphates in laundry detergents has been banned in the United States since 1993. State governments have also begun banning phosphates in dishwasher detergents. In response, manufacturers have introduced phosphate-free products.

Table 21.8 lists some uses of compounds of phosphorus.

## 21.10 Group 6A: Oxygen and the Sulfur Family

Group 6A, like the preceding groups, shows the trend from nonmetallic to metallic as you proceed from top to bottom of the column of elements. Oxygen and sulfur are strictly nonmetallic. Although the chemical properties of selenium and tellurium are predominantly those of nonmetals, they do have semiconducting allotropes as expected of metalloids. Polonium is a radioactive metal.

Oxygen, a second-period element, has rather different properties from those of the other members of Group 6A. It is very electronegative, and exists in compounds mainly in the  $-2$  oxidation state. The other Group 6A elements exist in compounds in this state also, but the  $+4$  and  $+6$  states are common. (Oxygen is the most abundant element on earth, making up 48% by mass of the earth's crust. Sulfur, although not as abundant as oxygen, is a common element. Both oxygen and sulfur are important to living organisms.)

### Oxygen

Oxygen in the form of dioxygen,  $\text{O}_2$ , makes up 20.9 mole percent of the atmosphere. Although this might seem to constitute a considerable quantity of the element, most of the oxygen on earth is present as oxide and oxoanion minerals (in silicates, carbonates, sulfates, and so forth). Indeed, oxygen combines with almost every element—only some of the noble gases have no known oxygen compounds. The chemistry of oxygen is therefore very important, though we frequently discuss it in the context of other elements. In fact, much of the chemistry of the elements discussed in this chapter concerns either their reactions with oxygen or the properties of their oxides and oxoacids.

**Properties and Preparation of Oxygen** The common form of the element oxygen is dioxygen,  $\text{O}_2$ . (The element also exists as the allotrope ozone,  $\text{O}_3$ .) Dioxygen, usually called simply oxygen, is a colorless, odorless gas under standard conditions. The critical temperature is  $-118^\circ\text{C}$ . Therefore, you can liquefy oxygen if you first cool the gas below this temperature and then compress it. Both liquid and solid  $\text{O}_2$  have a pale blue color. The melting point of the solid is  $-218^\circ\text{C}$ , and the boiling point at 1 atm is  $-183^\circ\text{C}$ . ▶

Oxygen is produced in enormous quantity from air. As described in the discussion of nitrogen, air is first liquefied, then distilled. Nitrogen and argon are more volatile components of air and distill off, leaving liquid oxygen behind.

Oxygen can be prepared in small quantities by decomposing certain oxygen-containing compounds. Both the Swedish chemist Karl Wilhelm Scheele and the British chemist Joseph Priestley are credited with the discovery of oxygen. Priestley obtained the gas in 1774 by heating mercury(II) oxide.

Ozone and its presence in the atmosphere are discussed in an essay at the end of Chapter 10.

**Figure 21.51** ▲

**Chromium oxides** Top: Chromium(III) oxide, a basic oxide. Bottom: Chromium(VI) oxide, an acidic oxide.

In one laboratory preparation, potassium chlorate,  $\text{KClO}_3$ , is heated with pure manganese(IV) oxide,  $\text{MnO}_2$ , as a catalyst.

**Reactions of Oxygen** Molecular oxygen is a very reactive gas and combines directly with many substances. The products are usually oxides. An **oxide** is a *binary compound with oxygen in the  $-2$  oxidation state*.

Most metals react readily with oxygen to form oxides, especially if the metal is in a form that exposes sufficient surface area. For example, magnesium wire and iron wool burn brightly in air to yield the oxides.

The resulting oxides  $\text{MgO}$  and  $\text{Fe}_3\text{O}_4$  are basic oxides, as is true of most metal oxides. If the metal is in a high oxidation state, however, the oxide may be acidic. For example, chromium(III) oxide,  $\text{Cr}_2\text{O}_3$ , is a basic oxide, but chromium(VI) oxide,  $\text{CrO}_3$ , is an acidic oxide (Figure 21.51).

The alkali metals form an interesting series of binary compounds with oxygen. When an alkali metal burns in air, the principal product with oxygen depends on the metal. With lithium, the product is the basic oxide,  $\text{Li}_2\text{O}$ . With the other alkali metals, the product is predominantly the peroxide and superoxide. A **peroxide** is a *compound with oxygen in the  $-1$  oxidation state*. (Peroxides contain either the  $\text{O}_2^{2-}$  ion or the covalently bonded group  $-\text{O}-\text{O}-$ .) A **superoxide** is a *binary compound with oxygen in the  $-\frac{1}{2}$  oxidation state*; superoxides contain the superoxide ion,  $\text{O}_2^-$ . Sodium metal burns in air to give mainly the peroxide.

Potassium and the other alkali metals form mainly the superoxides.

Nonmetals react with oxygen to form covalent oxides, most of which are acidic. For example, carbon burns in an excess of oxygen to give carbon dioxide, which is the acid anhydride of carbonic acid (that is, carbon dioxide produces carbonic acid when it reacts with water). Sulfur,  $\text{S}_8$ , burns in oxygen to give sulfur dioxide,  $\text{SO}_2$ , the acid anhydride of sulfurous acid.

Sulfur forms another oxide, sulfur trioxide,  $\text{SO}_3$ , but only small amounts are obtained during the burning of sulfur in air. Sulfur trioxide is the acid anhydride of sulfuric acid.

Compounds in which at least one element is in a reduced state are oxidized by oxygen, giving compounds that would be expected to form when the individual elements are burned in oxygen. For example, a hydrocarbon such as octane,  $\text{C}_8\text{H}_{18}$ , burns to give carbon dioxide and water.

Some other examples are given in the following equations:

Note the products that are formed; sulfur compounds usually form  $\text{SO}_2$ .

**CONCEPT CHECK 21.2**

Why do we need such low temperatures to liquefy gases such as nitrogen, oxygen, and helium?

## Sulfur

Sulfur occurs in sulfate minerals, such as gypsum ( $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ ), and in sulfide and disulfide minerals, many of which are important metal ores. Pyrite is iron(II) disulfide,  $\text{FeS}_2$ ; it consists of  $\text{Fe}^{2+}$  and  $\text{S}_2^{2-}$  ions. This mineral is sometimes called “fool’s gold,” because its golden color often fooled novice miners into thinking they had found gold. Sulfur is also present in coal and petroleum as organic sulfur compounds and in natural gas as hydrogen sulfide,  $\text{H}_2\text{S}$ . Free sulfur occurs in some volcanic areas, perhaps formed by the reaction of hydrogen sulfide and sulfur dioxide, which are present in volcanic gases.

Commercial deposits of free sulfur also occur in the rock at the top of salt domes, which are massive columns of salt embedded in rock a hundred meters or more below the earth’s surface. These deposits are believed to have formed by bacterial action involving calcium sulfate minerals. Figure 21.52 shows free sulfur obtained from such deposits that occur in the United States along the Gulf of Mexico.

Sulfur also occurs in several amino acids, which are the building blocks of the proteins in living organisms. Plants are able to use sulfate ion as a source of sulfur for the synthesis of amino acids. Animals and decay bacteria derive most of their nutritional sulfur from organic sources.

**Allotropes of Sulfur** Sulfur has a fascinating array of allotropes, including two common crystal forms, rhombic sulfur and monoclinic sulfur (see Figure 6.18). *Rhombic sulfur* is the stablest form of the element under normal conditions; natural sulfur is rhombic sulfur. It is a yellow, crystalline solid with a lattice consisting of crown-shaped  $\text{S}_8$  molecules (Figure 21.53). The relative stability of this molecule results in part from the ability of sulfur atoms to undergo catenation—that is, to form stable bonds to other sulfur atoms. Rhombic sulfur melts at  $113^\circ\text{C}$  to give an orange-colored liquid.

When this liquid is cooled, it crystallizes to give *monoclinic sulfur*. This allotrope also consists of  $\text{S}_8$  molecules; it differs from rhombic sulfur only in the way the molecules are packed to form crystals. Monoclinic sulfur melts at  $119^\circ\text{C}$ . It is unstable below  $96^\circ\text{C}$ , and in a few weeks at room temperature it reverts to rhombic sulfur.

If, instead of cooling the liquid sulfur, you raise its temperature above  $160^\circ\text{C}$ , the sulfur begins to darken and at somewhat higher temperatures changes to a dark reddish brown, viscous liquid. The original melt consists of  $\text{S}_8$  molecules, but these rings of sulfur atoms open up, and the fragments join to give long spiral chains of sulfur atoms. The spiral chains have unpaired electrons at their ends, and these unpaired electrons are responsible for the color. The viscosity of the liquid increases as compact  $\text{S}_8$  molecules are replaced by long spiral chains that can intertwine. At temperatures greater than  $200^\circ\text{C}$ , the chains begin to break apart and the viscosity decreases. Figure 21.54 shows the appearance of sulfur at various temperatures.

When molten sulfur above  $160^\circ\text{C}$  (but below  $200^\circ\text{C}$ ) is poured into water, the liquid changes to a rubbery mass, called *plastic sulfur*. Plastic sulfur is an amorphous mixture of sulfur chains. The rubberiness of this sulfur results from the ability of the spiral chains of sulfur atoms to stretch and then relax to their original length. Plastic sulfur reverts to rhombic sulfur after a period of time.

Sulfur boils at  $445^\circ\text{C}$ , giving a vapor of  $\text{S}_8$ ,  $\text{S}_6$ ,  $\text{S}_4$ , and  $\text{S}_2$  molecules. Measurements of vapor density depend on the temperature, as a result of these different species of molecular sulfur in the vapor. (The relationship between gas density and molecular weight is described in Section 5.3.)

**Production of Sulfur** Free sulfur that occurs in deep underground deposits is mined by the **Frasch process**, a mining procedure in which underground deposits of solid sulfur are melted in place with superheated water, and the molten sulfur is forced upward as a froth using air under pressure (see Figure 21.55). A sulfur well is similar to an oil

Figure 21.52 ▲

**Sulfur obtained from underground deposits** Sulfur is obtained from these deposits by pumping in superheated water; molten sulfur is then pumped to the earth’s surface. (Details of this *Frasch process* are described later.) Here, molten sulfur from a well is being directed to an area where it can cool and solidify.

Figure 21.53 ▲

## The Frasch process for mining

**sulfur** The well consists of concentric pipes. Superheated water passing down the outer pipe exits into the sulfur deposit, melting it. Compressed air from the inner pipe pushes the molten sulfur up the middle pipe. Molten sulfur flows from the top of the well onto the ground to cool.

well but consists of three concentric pipes. Superheated water flows down the outer pipe, and compressed air flows down the inner pipe. The superheated water melts the sulfur, which is then pushed up the middle pipe by the compressed air. Molten sulfur spews from the well and solidifies in large storage areas. Sulfur obtained this way is 99.6% pure.

Hydrogen sulfide,  $\text{H}_2\text{S}$ , recovered from natural gas and petroleum is also a source of free sulfur. The sulfur is obtained from the hydrogen sulfide gas by the **Claus process**, a method of obtaining free sulfur by the partial burning of hydrogen sulfide. The partial burning of hydrogen sulfide produces some sulfur, as well as sulfur dioxide.

The sulfur dioxide that forms reacts with the hydrogen sulfide to produce more sulfur.

Most of the sulfur produced (almost 90%) is used to make sulfuric acid. The remainder has a wide variety of uses, including the vulcanization of rubber (sulfur converts the initially tacky material into useful rubber), the production of carbon disulfide (to make cellophane), and the preparation of sulfur dioxide for bleaching.

**Sulfur Oxides and Oxoacids** Sulfur dioxide,  $\text{SO}_2$ , is a colorless, toxic gas with a characteristic suffocating odor. Its presence in polluted air (from the burning of fossil fuels) is known to cause respiratory ailments. The  $\text{SO}_2$  molecule has a bent geometry with a bond angle of  $119.5^\circ$ , very close to that predicted by the VSEPR model (Figure 21.56).

Sulfur dioxide gas is very soluble in water, producing acidic solutions. Although these solutions are often referred to as solutions of *sulfurous acid*, they appear to be composed primarily of hydrated species of  $\text{SO}_2$ ; the acid  $\text{H}_2\text{SO}_3$  has never been isolated. An aqueous solution of sulfur dioxide,  $\text{SO}_2(aq)$ , does apparently contain small amounts of the ions  $\text{HSO}_3^-$  and  $\text{SO}_3^{2-}$ , which would be expected to be produced by the ionization of  $\text{H}_2\text{SO}_3$ .

When an appropriate amount of base is added to an aqueous solution of sulfur dioxide, the corresponding hydrogen sulfite salt or sulfite salt is obtained. Sodium hydrogen sulfite (also called sodium bisulfite) and sodium sulfite are produced this way commercially using sodium carbonate as the base:

Sulfites and hydrogen sulfites decompose when treated with acid to give sulfur dioxide. For example,

This reaction can be used to prepare small amounts of sulfur dioxide in the laboratory.

Sulfur dioxide is produced on a large scale by burning sulfur,  $\text{S}_8$ . It is also obtained as a by-product of the roasting of sulfide ores (such as  $\text{FeS}_2$ ,  $\text{CuS}$ ,  $\text{ZnS}$ , and  $\text{PbS}$ ). Most of this sulfur dioxide is used to prepare sulfuric acid. Some is used as a bleach for wood pulp and textiles (Figure 21.57) and as a disinfectant and food preservative (for example, in wine and dried fruit). Its use as a food preservative depends on the fact that sulfur dioxide is especially toxic to yeasts, molds, and certain bacteria. Because some people are allergic to sulfur dioxide, foods containing it must be properly labeled.

Sulfur trioxide is a liquid at room temperature. The liquid actually consists of  $\text{S}_3\text{O}_9$  molecules in equilibrium with  $\text{SO}_3$  molecules (Figure 21.58). The vapor-phase molecule is  $\text{SO}_3$ , which has a planar triangular geometry.

Sulfur trioxide is formed in small amounts when sulfur is burned in air, although the principal product is sulfur dioxide. Thermodynamically, sulfur trioxide is the preferred product of sulfur and oxygen. Sulfur dioxide does react slowly with oxygen in air to produce sulfur trioxide, but the reaction is much faster in the presence of a catalyst, such as platinum. Sulfur trioxide is produced commercially by the oxidation of sulfur dioxide in the presence of vanadium(V) oxide catalyst.

**Figure 21.56** ▲

and iodides. Calcium chloride, bromide, and iodide are very soluble in water. Calcium fluoride, however, is insoluble. Silver chloride, bromide, and iodide are insoluble, but silver fluoride is soluble.

All of the halogens form stable compounds in which the element is in the  $-1$  oxidation state. In fluorine compounds, this is the only oxidation state. Chlorine, bromine, and iodine also have compounds in which the halogen is in one of the positive oxidation states  $+1$ ,  $+3$ ,  $+5$ , or  $+7$ . The higher positive oxidation states ( $> +1$ ) may be due to the larger size of the halogen atom.

## Chlorine

Chlorine gas,  $\text{Cl}_2$ , was discovered in 1774 by the Swedish chemist Karl Wilhelm Scheele by heating hydrochloric acid with manganese dioxide.

He immediately noted the suffocating odor of the gas. Scheele also discovered that chlorine solutions could bleach cotton cloth. Within a few decades, chlorine-based bleaches became major items of commerce. Currently, chlorine is the most commercially important halogen.

**Properties of Chlorine** Chlorine gas has a pale greenish yellow color. It is a very reactive oxidizing agent and supports the oxidation of many substances in a manner similar to oxygen. We discussed the reaction of chlorine with sodium in Chapter 2. ▶

See the introduction to chapter 2.

All of the halogens are oxidizing agents, though the oxidizing power decreases from fluorine to iodine. Thus, chlorine is a stronger oxidizing agent than either bromine or iodine. When chlorine gas is bubbled into a bromide solution, free bromine is obtained. Similarly, chlorine oxidizes iodide ion to iodine.

These reactions can be used as a test for bromide and iodide ions. Suppose an aqueous solution of chlorine is added to a test tube containing either bromide or iodide ion. The corresponding free halogen is formed in the water solution. It is readily identified by adding the organic solvent methylene chloride,  $\text{CH}_2\text{Cl}_2$ , which dissolves the halogen, forming a colored layer at the bottom of the test tube. Bromide ion gives an orange layer; iodide ion gives a violet layer. Of course, neither bromine nor iodine is strong enough to oxidize chloride ion.

Chlorine reacts with water by being both oxidized and reduced:

In an aqueous solution of chlorine at  $25^\circ\text{C}$ , about two-thirds of the chlorine is present as  $\text{Cl}_2(aq)$ ; the rest is  $\text{HClO}$  and  $\text{HCl}$ .

**Preparation and Uses of Chlorine** Chlorine is a major industrial chemical. It is prepared commercially by the electrolysis of aqueous sodium chloride. ▶ Chlorine can be prepared in small amounts for laboratory use by the reaction of chloride ion with a strong oxidizing agent, such as potassium dichromate or manganese dioxide. However, chlorine is readily available in steel cylinders for laboratory work.

The electrolysis of aqueous sodium chloride is discussed in Section 19.10.

The principal use of chlorine is in the preparation of chlorinated hydrocarbons, such as vinyl chloride,  $\text{CH}_2=\text{CHCl}$  (for polyvinyl chloride plastics), and methyl chloride,  $\text{CH}_3\text{Cl}$  (for the manufacture of silicones, polymers with  $\text{Si}-\text{O}$  bonds and organic groups). Various insecticides are also chlorinated hydrocarbons; many of these (such as DDT) are now restricted in their use because of possible environmental damage.

Other major uses of chlorine are as a bleaching agent for textiles and paper pulp and as a disinfectant. Not long after the discovery of chlorine, chlorine bleaches became available commercially. Chlorine solutions were used as disinfectants early in the nineteenth century. Today, chlorine gas is commonly used for disinfecting municipal water supplies.

© Cengage Learning

**Figure 21.59** ▲

**The hydrogen chloride fountain** The flask contains hydrogen chloride gas. When water is added to the flask from the dropper, the hydrogen chloride dissolves in it, reducing the pressure in the flask. Atmospheric pressure pushes the water in the beaker into the flask, forming a stream or fountain. Water in the beaker has bromthymol-blue indicator in it. The indicator solution in the flask is yellow because it is acidic.

**Hydrogen Chloride** Hydrogen chloride, HCl, is a colorless gas with a sharp, penetrating odor. The gas is very soluble in water (Figure 21.59), and the water solution is commonly referred to as hydrochloric acid. The molecular species HCl ionizes nearly completely in aqueous solution:

Hydrogen chloride can be produced by heating sodium chloride with concentrated sulfuric acid.

On stronger heating, the sodium hydrogen sulfate reacts with sodium chloride to produce additional hydrogen chloride.

Hydrogen bromide and hydrogen iodide can also be produced from their salts by a similar replacement reaction, but in these cases phosphoric acid is used instead of sulfuric acid, which tends to oxidize the bromide and iodide ions to the respective elements (Figure 21.60).

Most of the hydrogen chloride available commercially is obtained as a by-product in the manufacture of chlorinated hydrocarbons. In these reactions, hydrogen bonded to carbon is replaced by chlorine, forming the chlorinated compound and HCl. An example is the preparation of methyl chloride, CH<sub>3</sub>Cl, from methane.

Hydrochloric acid is the fourth most important industrial acid (after sulfuric, phosphoric, and nitric acids). It is used to clean metal surfaces of oxides (a process called *pickling*) and to extract certain metal ores, such as those of tungsten.

**Oxoacids of Chlorine** The halogens form a variety of oxoacids (Table 21.10). Figure 21.61 shows the structures of the chlorine oxoacids. The acidic character of these acids increases with the number of oxygen atoms bonded to the halogen atom—that

**Figure 21.60** ►

\*The oxidation state of F in HFO is -1.

†These acids are known only in aqueous solution.

**Figure 21.61** ▲

**Structures of the chlorine oxoacids** The models of the oxoacids also include lone pairs on the Cl atom.

is, in the order  $\text{HClO}$ ,  $\text{HClO}_2$ ,  $\text{HClO}_3$ ,  $\text{HClO}_4$ . (See Section 15.5 for a discussion of molecular structure and acid strength.) Perchloric acid,  $\text{HClO}_4$ , is the strongest of the common acids. Of the chlorine oxoacids, only perchloric acid is stable; the other oxoacids have never been isolated and are known only in aqueous solution.

Hypochlorous acid,  $\text{HClO}$ , is produced when chlorine disproportionates (is oxidized and reduced) in water. In basic solution, the equilibrium is very far toward the acid anions:

Solutions of sodium hypochlorite are manufactured by allowing the chlorine gas released by the electrolysis of aqueous sodium chloride to mix with the cold solution of sodium hydroxide that is also obtained in the electrolysis. These solutions are sold as a bleach (Figure 21.62).

Hypochlorite ion itself is unstable, disproportionating into chlorate ion,  $\text{ClO}_3^-$ , and chloride ion.

At room temperature the reaction is slow; but in hot solution in the presence of base, the reaction is fast. Therefore, when chlorine reacts with hot sodium hydroxide solution, sodium chlorate is the product instead of sodium hypochlorite.

Sodium chlorate can be crystallized from the solution. Solutions of chloric acid,  $\text{HClO}_3$ , can be prepared, although the pure acid cannot be isolated.

Sodium perchlorate and potassium perchlorate are produced commercially by the electrolysis of a saturated solution of the corresponding chlorate. The anode reaction is

Hydrogen evolves at the cathode. Perchloric acid can be prepared by treating a perchlorate salt with sulfuric acid.

The perchloric acid is distilled from the mixture at reduced pressure (to keep the temperature below  $92^\circ\text{C}$ , where perchloric acid decomposes explosively).

Table 21.11 lists uses of some halogen compounds.

## 21.12 Group 8A: The Noble Gases

In our discussions of bonding, we pointed out the relative stability of the electron configurations of the Group 8A noble gases. For many years, it was thought that because the atoms of these elements had completed octets, the noble gases would be completely unreactive. Consequently, these elements were known as *inert gases*.

**Figure 21.62** ▲

Compounds of argon, krypton, xenon, and radon have since been prepared, however, so the term is not quite appropriate. The discovery of element 118, ununoctium, was reported in 2002, and has been placed below radon in the periodic table, although there is no known chemistry of the element (other than theoretical calculations).

### Helium and the Other Noble Gases

The noble gases were not known until 1894. A couple of years earlier, the English physicist Lord Rayleigh discovered that the density of nitrogen gas obtained from air (1.2561 g/L at STP) was noticeably greater than the density of nitrogen obtained by decomposition of nitrogen compounds (1.2498 g/L at STP). He concluded that one of these two nitrogen sources was contaminated with another substance.

Soon after this, Rayleigh began collaborating with the Scottish chemist William Ramsay. Ramsay passed atmospheric nitrogen over hot magnesium to remove the nitrogen as magnesium nitride, Mg<sub>3</sub>N<sub>2</sub>, and obtained a nonreactive residual gas. He placed this gas in a sealed glass tube and passed a high-voltage electrical discharge through it to observe its emission spectrum. The spectrum showed a series of red and green lines and was unlike that of any known element. Ramsay and Rayleigh concluded that they had discovered a new element, which they called argon (from the Greek word *argos*, meaning “lazy”—referring to argon’s lack of chemical reactivity). They also surmised that argon was a member of a new column of elements in the periodic table.

Before the discovery of argon, some lines in the spectrum of the sun were ascribed to an element not yet known on earth. This element was called helium (from the Greek *helios*, meaning “sun”). In 1895, Ramsay and the Swedish chemist Per Theodor Cleve (working independently) announced the discovery of helium gas in the mineral cleveite (a uranium ore) by identifying the spectrum of helium. Several years later, Ramsay discovered neon, krypton, and xenon by fractional distillation of liquid air. Radon was discovered in 1900 as a gaseous decay product of radium.

**Preparation and Uses of the Noble Gases** Commercially, all the noble gases except helium and radon are obtained by the distillation of liquid air. The principal sources of helium are certain natural-gas wells. Helium has the lowest boiling point (−268.9°C) of any substance and is very important in low-temperature research. The major use of argon is as a blanketing gas (inert gas) in metallurgical processes. It is also used as a mixture with nitrogen to fill incandescent lightbulbs. In these bulbs the gas mixture conducts heat away from the hot tungsten filament, without reacting with it. All the noble gases are used in gas discharge tubes (containing gas through which a high-voltage electric current can be discharged, giving light from atomic emission). Neon gives a highly visible red-orange emission and has long been used in advertising signs. The noble gases are also used in a number of lasers. The helium–neon laser was the first continuously operating gas laser. It emits red light at a wavelength of 632.8 nm.

Compound	Formula	Description
Xenon difluoride	XeF <sub>2</sub>	Colorless crystals
Xenon tetrafluoride	XeF <sub>4</sub>	Colorless crystals
Xenon hexafluoride	XeF <sub>6</sub>	Colorless crystals
Xenon trioxide	XeO <sub>3</sub>	Colorless crystals, explosive
Xenon tetroxide	XeO <sub>4</sub>	Colorless gas, explosive

**Compounds of the Noble Gases** Neil Bartlett, working at the University of British Columbia, prepared the first noble-gas compound after he discovered that molecular oxygen reacts with platinum hexafluoride, PtF<sub>6</sub>, to form the ionic solid [O<sub>2</sub><sup>+</sup>][PtF<sub>6</sub><sup>-</sup>]. Because the ionization energy of xenon ( $1.17 \times 10^3$  kJ/mol) is close to that of molecular oxygen ( $1.21 \times 10^3$  kJ/mol), Bartlett reasoned that xenon should also react with platinum hexafluoride. In 1962, he reported the synthesis of an orange-yellow compound with the approximate formula XePtF<sub>6</sub>. Later in the same year, chemists from Argonne National Laboratory near Chicago reported that xenon reacts directly with fluorine at 400°C to give the tetrafluoride. The elements react even at room temperature when exposed to sunlight.

The product is a volatile, colorless solid (Figure 21.63). Since then, a number of noble-gas compounds have been prepared that typically involve bonds to the highly electronegative elements fluorine and oxygen. Most of these are compounds of xenon (see Table 21.12), but a few are compounds of krypton and radon. Recently, an argon compound, HArF, was synthesized.

Argonne National Laboratory

**Figure 21.63** ▲

**Crystals of xenon tetrafluoride**

This photomicrograph shows crystals obtained in the experiment that first produced a binary compound of xenon.

The product actually has variable composition and can be represented by the formula Xe(PtF<sub>6</sub>)<sub>n</sub>, where n is between 1 and 2.

## ✓ A Checklist for Review

### Summary of Facts and Concepts

Several general observations can be made about the main-group elements. First, the metallic characteristics of these elements generally decrease across a period from left to right in the periodic table. Second, metallic characteristics of the main-group elements become more pronounced going down any column (group). Finally, a second-period element is usually rather different from the other elements in its group.

*Metals* may be pure elements, or they may be *alloys*, which can be either compounds or mixtures. Metallic elements and their compounds are obtained principally from the earth's crust, most of which is composed of metal silicates. The chief sources of metals, however, are not silicates but oxide, carbonate, and sulfide *minerals*, which exist in *ore* deposits widely scattered over the earth.

An important part of *metallurgy* is the production of metals from their ores. This involves three basic steps: *preliminary treatment*, *reduction*, and *refining*. In preliminary treatment, the ore is concentrated in its metal-containing mineral. The concentrated ore may also require a process such as *roasting*, in which the metal compound is transformed to one that is more easily reduced. In reduction, the metal compound is reduced to the metal, by either

electrolysis or chemical reduction. In refining, the metal is purified, or freed of contaminants.

The *electron-sea model* is a simple depiction of a metal as an array of positive ions surrounded by delocalized valence electrons. Molecular orbital theory gives a more detailed picture of the bonding in metals. Because the energy levels in a metal crowd together into bands, this picture of metal bonding is often referred to as *band theory*. According to band theory, the electrons in a crystal become free to move when they are excited to the unoccupied orbitals of a band. In a metal, this requires very little energy, because unoccupied orbitals lie just above the occupied orbitals of highest energy.

The Group 1A metals (alkali metals) are soft, chemically reactive elements. Lithium, sodium, and potassium are important alkali metals. In recent years, the commercial uses of lithium have grown markedly. The metal is obtained by the electrolysis of molten lithium chloride and is used in the production of low-density alloys and as a battery anode. Lithium hydroxide is used to make lithium soap for lubricating greases; it is produced by the reaction of lithium carbonate and calcium hydroxide.

Sodium metal is prepared in large quantities. It is used as a reducing agent in the preparation of other metals,

such as titanium and zirconium, and in the preparation of dyes and pharmaceuticals. Sodium compounds are of enormous economic importance. Sodium chloride is the source of sodium and most of its compounds. Sodium hydroxide is prepared by the electrolysis of aqueous sodium chloride; as a strong base, it has many useful commercial applications, including aluminum production and petroleum refining. Sodium carbonate is obtained from the mineral trona, which contains sodium carbonate and sodium hydrogen carbonate, and by the *Solvay process* from salt (NaCl) and limestone (CaCO<sub>3</sub>). Sodium carbonate is used to make glass. Potassium metal is produced in relatively small quantities, but potassium compounds are important. Large quantities of potassium chloride are used as a plant fertilizer.

Magnesium and calcium are the most important of the Group 2A (alkaline earth) metals. Magnesium and its alloys are important structural metals. Calcium is important primarily as its compounds, which are prepared from natural carbonates, such as limestone, and the sulfates, such as gypsum. When limestone is heated strongly, it decomposes to calcium oxide (lime). Enormous quantities of lime are used in the production of iron from its ores.

Of the Group 3A and Group 4A metals, aluminum, tin, and lead are especially important. Aluminum is the third most abundant element in the earth's crust. It is obtained commercially from bauxite; through chemical processing bauxite yields pure aluminum oxide. Most of this aluminum oxide is used in the production of aluminum by electrolysis. Some aluminum oxide is used as a carrier for heterogeneous catalysts and in manufacturing industrial ceramic materials.

Tin is normally a metal (called white tin) but does undergo a low-temperature conversion to a nonmetallic form (called gray tin). Tin is obtained by reduction of cassiterite, a mineral form of SnO<sub>2</sub>. Tin is used to make tin plate, bronze, and solder. Lead is obtained from galena, which is a sulfide ore, PbS. More than half of the lead produced is used to make electrodes for lead storage batteries. Litharge, or lead(II) oxide, is an important lead compound from which other lead compounds are prepared.

Carbon and tin are the least metallic of the Group 4A elements. *Catenation* is an important feature of carbon chemistry and is responsible for the enormous number of organic compounds. Carbon has several allotropes, the principal ones being diamond and graphite, which are covalent-network solids, and buckminsterfullerene, which is molecular (C<sub>60</sub>). The element has important industrial uses, including carbon black for rubber tires. The principal oxides of carbon are CO and CO<sub>2</sub>. Mixtures of carbon monoxide and hydrogen (synthesis gas) are used to prepare various organic compounds. Liquid and solid carbon dioxide are used as refrigerants, and the gas is used to make carbonated beverages.

Hydrogen is the most abundant element in the universe and is the third most abundant element on the surface of the earth. Most of the hydrogen on earth is found in water. Hydrogen has three isotopes: *protium*, *deuterium*, and *tritium*. Protium is the most abundant, with less than 0.02% being deuterium and only a trace being radioactive tritium. Deuterium and tritium isotopes can be substituted for protium in chemical compounds in

order to provide markers that can be followed during a chemical reaction or to change the chemical and physical properties of the compound. Elemental hydrogen is produced on an industrial scale by the *steam-reforming process* in which a hydrocarbon is reacted with water in the presence of a catalyst at high temperature. The bulk of the hydrogen produced in this manner is used to make organic compounds including methanol. Hydrogen forms three classes of binary compounds called binary hydrides: *ionic hydrides*, covalent hydrides, and metallic hydrides. The ionic hydrides are reactive solids formed either by the reaction of hydrogen with an alkali metal to form compounds with the general formula MH, or with larger alkaline earth metals to form MH<sub>2</sub>. The *covalent hydrides* are compounds in which hydrogen is covalently bonded to another element. The *metallic hydrides* contain a transition metal element and hydrogen. In these compounds, the lattice of metal atoms forms a porous structure that allows hydrogen atoms to enter and bond. Metallic hydrides are often nonstoichiometric, meaning that the ratio of hydrogen atoms to metal atoms is not a whole number.

Silicon is a prominent material of technology. The element is the basic material used in semiconductor devices for solid-state electronics. These devices require silicon of extreme purity. The impure element is converted to silicon tetrachloride, which is purified by distillation, after which the silicon tetrachloride is reduced to the pure silicon. *Silica* is chemically known as silicon dioxide; quartz is a common form of silica. It exhibits the *piezoelectric effect*, which is used to control radio, television, and clock frequencies. *Silicates* are formed by *condensation reactions*, and an enormous variety of silicate minerals exists. The *silicones* are materials that contain chains of Si—O bonds, with hydrocarbon groups attached to Si atoms. They have wide applications, including their use as elastomers and lubricants.

Of the Group 5A elements, nitrogen and phosphorus are particularly important. Nitrogen, N<sub>2</sub>, is obtained from liquid air by fractional distillation; liquid nitrogen is used as a refrigerant. Ammonia, NH<sub>3</sub>, is the most important compound of nitrogen. It is prepared from the elements and is used as a fertilizer. Ammonia is also the starting compound for the manufacture of other nitrogen compounds. For example, in the *Ostwald process* for the preparation of nitric acid, ammonia is burned in the presence of a catalyst to nitrogen monoxide (nitric oxide). NO reacts with oxygen to give nitrogen dioxide, which reacts with water to give nitric acid.

Phosphorus has two common allotropes, white phosphorus (P<sub>4</sub>) and red phosphorus (chain structure). White phosphorus is obtained by heating a phosphate mineral with sand and coke in an electric furnace. When phosphorus burns in air, it forms tetraphosphorus decoxide, P<sub>4</sub>O<sub>10</sub>. This oxide reacts with water to give orthophosphoric acid, H<sub>3</sub>PO<sub>4</sub>. Phosphorus has many oxoacids; most are obtained by condensation reactions with orthophosphoric acid. One series is called the *polyphosphoric acids*; they have the general formula H<sub>n+2</sub>P<sub>n</sub>O<sub>3n+1</sub>. Triphosphoric acid is an example; sodium triphosphate, Na<sub>5</sub>P<sub>3</sub>O<sub>10</sub>, is used in detergents. The *metaphosphoric acids* have the general formula (HPO<sub>3</sub>)<sub>n</sub>.

Oxygen, a Group 6A element, occurs in the atmosphere (as  $O_2$ ), but mostly it is present on earth as oxide and oxoanion minerals. Oxygen has two allotropes: dioxygen,  $O_2$ , and ozone,  $O_3$ . Dioxygen, usually called simply oxygen, is obtained commercially from liquid air. Oxygen reacts with almost all elements to give *oxides* or, in some cases, *peroxides* or *superoxides*.

Sulfur, another Group 6A element, occurs in sulfate and sulfide minerals. Free sulfur,  $S_8$ , occurring in deep underground deposits is mined by the *Frasch process*. Sulfur is also produced by the *Claus process*, in which hydrogen sulfide (obtained from natural gas and petroleum) is partially burned. Most of the sulfur is used to prepare sulfuric acid by the *contact process*. In this process, sulfur is burned to sulfur dioxide,  $SO_2$ , which in the presence of a catalyst and oxygen forms sulfur trioxide,

$SO_3$ . This oxide dissolves in concentrated sulfuric acid, which when diluted with water gives additional sulfuric acid. Sulfuric acid is the most important compound of sulfur.

The Group 7A elements, or halogens, are reactive. Chlorine ( $Cl_2$ ), a pale greenish yellow gas, is prepared commercially by the electrolysis of aqueous sodium chloride. Its principal uses are in the preparation of chlorinated hydrocarbons and as a bleaching agent and disinfectant. Hydrogen chloride,  $HCl$ , is one of the most important compounds of chlorine; aqueous solutions of  $HCl$  are known as hydrochloric acid.

The Group 8A elements, the noble gases, were discovered at the end of the nineteenth century. Although the noble gases were at first thought to be unreactive, compounds of these gases are now known.

## Learning Objectives

## Important Terms

### 21.1 General Observations About the Main-Group Elements

- Note the low ionization energies and electronegativities of the metals.
- Give the principal oxidation states of the main-group elements.
- State the periodic trends in metallic characteristics.

### 21.2 Metals: Characteristics and Production

- Define *metal*, *alloy*, *mineral*, and *ore*.
- Define *metallurgy*.
- State the basic steps in the production of a metal.
- Define the *Bayer process*.
- Describe the roasting of lead sulfide ore.
- Describe the electrolysis of molten lithium chloride.
- Define the *Dow process*.
- Define the *Hall-Héroult process*.
- Describe the chemical reduction of lead(II) oxide to lead metal.
- Give some methods for refining metals.

**metal**  
**alloy**  
**mineral**  
**ore**  
**metallurgy**  
**Bayer process**  
**roasting**  
**Dow process**  
**Hall-Héroult process**

### 21.3 Bonding in Metals

- Describe the electron-sea model of metals.
- Describe the molecular orbital theory of sodium and magnesium metals.

### 21.4 Group 1A: The Alkali Metals

- Note the reactivity of the alkali metals.
- Describe the metallurgy, reactions, and compounds of lithium.
- Describe the metallurgy, reactions, and compounds of sodium.
- Define the *Solvay process*.
- Describe some compounds of potassium.

**Solvay process**

### 21.5 Group 2A: The Alkaline Earth Metals

- Describe the metallurgy, reactions, and compounds of magnesium.
- Describe the metallurgy, reactions, and compounds of calcium.

## Questions and Problems

### Self-Assessment and Review Questions

**Key:** These questions test your understanding of the ideas you worked with in the chapter. These problems vary in difficulty and often can be used for the basis of discussion.

- 21.1 What is an alloy? Give an example.  
 21.2 Give four characteristics of a metal.  
 21.3 Define *mineral*, *rock*, and *ore*. Is bauxite a mineral or a rock? Explain.  
 21.4 What are the basic steps in the production of a pure metal from a natural source? Illustrate each step with the preparation of aluminum.  
 21.5 What is the purpose of roasting lead(II) ore?  
 21.6 Briefly describe three different methods for refining a metal.  
 21.7 Write equations for the preparation of magnesium metal from seawater, limestone, and hydrochloric acid.  
 21.8 Draw a flowchart for the preparation of aluminum from its ore. Label each step.  
 21.9 Explain metallic conduction in terms of molecular orbital theory (band theory).  
 21.10 Give the commercial source of each of the following metals: Li, Na, Mg, Ca, Al, Sn, Pb.  
 21.11 Give equations for the reactions of lithium and sodium metals with water and with oxygen in air.  
 21.12 Write the equation for the reaction of lithium carbonate with barium hydroxide.  
 21.13 Which do you expect to be more reactive, lithium or potassium? Explain.  
 21.14 Ethanol,  $C_2H_5OH$ , reacts with sodium metal because the hydrogen atom attached to the oxygen atom is slightly acidic. Write a balanced equation for the reaction of sodium with ethanol to give the salt sodium ethoxide,  $NaOC_2H_5$ .  
 21.15 **a** Write electrode half-reactions for the electrolysis of fused sodium chloride. **b** Do the same for fused sodium hydroxide. The hydroxide ion is oxidized to oxygen and water.  
 21.16 How is sodium hydroxide manufactured? What is another product in this process?  
 21.17 Describe common uses of the following sodium compounds: sodium chloride, sodium hydroxide, and sodium carbonate.  
 21.18 Describe the main step in the Solvay process. Give the balanced equation for this reaction.  
 21.19 Because magnesium reacts with oxygen, steam, and carbon dioxide, magnesium fires are extinguished only by smothering the fire with sand. Write balanced equations for the reactions of magnesium with  $O_2$ ,  $H_2O(g)$ , and  $CO_2$ .  
 21.20 **a** Calcium oxide is prepared industrially from what calcium compound? Write the chemical equation for the reaction. **b** Write the equation for the preparation of calcium hydroxide.  
 21.21 Calcium carbonate is used in some antacid preparations to neutralize the hydrochloric acid in the stomach. Write the equation for this neutralization.  
 21.22 Purified calcium carbonate is prepared by precipitation. Write the equation for the commercial process using

carbon dioxide. You can also prepare calcium carbonate by precipitation using sodium carbonate. Write the equation.

- 21.23 Write the chemical equation of the thermite reaction, in which iron(III) oxide is reduced by aluminum.  
 21.24 What are some major uses of aluminum oxide?  
 21.25 How is aluminum sulfate used to purify municipal water supplies?  
 21.26 Lead(IV) oxide forms the cathode of lead storage batteries. How is this substance produced for these batteries?  
 21.27 Why are lead pigments no longer used in house paints?  
 21.28 The yellow paint pigment chrome yellow [lead(II) chromate] is produced by a precipitation reaction. Write an equation in which chrome yellow is produced from lead(II) nitrate.  
 21.29 Describe the reactions that are used in the steam-reforming process for the production of hydrogen.  
 21.30 Give the names and symbols for the three isotopes of hydrogen. Which isotope is radioactive?  
 21.31 Explain why hydrogen has the potential to be widely used as a fuel.  
 21.32 Give an example of a compound of each of the binary hydrides.  
 21.33 What is meant by the term *catenation*? Give an example of a carbon compound that displays catenation.  
 21.34 Carbon monoxide is a poisonous gas. What is the mechanism of this poisoning?  
 21.35 Write equations for the equilibria involving carbon dioxide in water.  
 21.36 Describe the steps in preparing ultrapure silicon from quartz sand.  
 21.37 Use structural formulas to illustrate the hypothetical condensation reaction of two silicic acid molecules,  $Si(OH)_4$ .  
 21.38 Describe the natural cycle of nitrogen from the atmosphere to biological organisms and back to the atmosphere.  
 21.39 Describe Rutherford's preparation of nitrogen from air. Was the gas he obtained pure nitrogen? Explain.  
 21.40 List the different nitrogen oxides. What is the oxidation number of nitrogen in each?  
 21.41 In your own words, describe the manufacture of ammonia from natural gas, steam, and air.  
 21.42 Describe the steps in the Ostwald process for the manufacture of nitric acid from ammonia.  
 21.43 Describe the structure of white phosphorus. How does the structure account for the reactivity of this substance?  
 21.44 Give chemical equations for the reaction of white phosphorus in an excess of air and for the reaction of the product with water.  
 21.45 Describe two different methods used to manufacture phosphoric acid,  $H_3PO_4$ , starting from  $Ca_3(PO_4)_2$ .  
 21.46 By means of an equation, show how triphosphoric acid could be formed from orthophosphoric acid and diphosphoric acid.  
 21.47 What is the purpose of adding polyphosphates to a detergent?

- 21.48** What reaction was used by Priestley in preparing pure oxygen?
- 21.49** What is the most important commercial means of producing oxygen?
- 21.50** Define *oxide*, *peroxide*, and *superoxide*. Give an example of each.
- 21.51** Give an example of an acidic oxide and a basic oxide.
- 21.52** List three natural sources of sulfur or sulfur compounds.
- 21.53** Describe the structure of the rhombic sulfur molecule.
- 21.54** Discuss the various allotropes of sulfur and describe how they can be prepared from rhombic sulfur.
- 21.55** Describe the Frasch process for mining sulfur.
- 21.56** With the aid of chemical equations, describe the Claus process for the production of sulfur from hydrogen sulfide.
- 21.57** Give equations for preparing each of the following:  
**a** H<sub>2</sub>S    **b** SO<sub>2</sub>
- 21.58** Give equations for the steps in the contact process for the manufacture of sulfuric acid from sulfur.
- 21.59** Write equations for each of the following.  
**a** reaction of H<sub>2</sub>S with SO<sub>2</sub>  
**b** oxidation of SO<sub>2</sub> with Cr<sub>2</sub>O<sub>7</sub><sup>2-</sup>(aq) to SO<sub>4</sub><sup>2-</sup>  
**c** reaction of hot, concentrated H<sub>2</sub>SO<sub>4</sub> with Cu  
**d** reaction of sulfur with Na<sub>2</sub>SO<sub>3</sub>
- 21.60** Give the equation for the reaction used by the Swedish chemist Scheele to prepare chlorine.
- 21.61** Complete and balance the following equations. Write *NR* if no reaction occurs.  
**a** I<sub>2</sub>(aq) + Cl<sup>-</sup>(aq) →  
**b** Cl<sub>2</sub>(aq) + Br<sup>-</sup>(aq) →  
**c** Br<sub>2</sub>(aq) + I<sup>-</sup>(aq) →  
**d** Br<sub>2</sub>(aq) + Cl<sup>-</sup>(aq) →
- 21.62** A test tube contains a solution of one of the following salts: NaCl, NaBr, NaI. Describe a single test that can distinguish among these possibilities.
- 21.63** What are some major commercial uses of chlorine?
- 21.64** How is sodium hypochlorite prepared? Give the balanced chemical equation.
- 21.65** Describe the preparation of perchloric acid from sodium chloride.
- 21.66** What was the argument used by Bartlett that led him to the first synthesis of a noble-gas compound?
- 21.67** Which of the following are used in the production of H<sub>2</sub>(g)?  
 I. steam-reforming process  
 II. water-gas reaction  
 III. Haber process  
**a** I only  
**b** II only  
**c** III only  
**d** I and II only  
**e** II and III only
- 21.68** In which of the following is nitrogen or nitrogen-containing compounds *not* used?  
**a** fertilizer    **b** explosives    **c** dental anesthetic  
**d** blanketing gas    **e** jet fuel
- 21.69** The major use of Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> is in  
**a** the tempering of metals  
**b** phosphorus for fireworks  
**c** acid neutralization  
**d** the production of phosphoric acid  
**e** the vulcanization of rubber
- 21.70** Sodium hypochlorite is used in laundry bleach. The formula of sodium hypochlorite is  
**a** NaCl    **b** NaClO    **c** NaClO<sub>2</sub>  
**d** NaClO<sub>3</sub>    **e** NaClO<sub>4</sub>

## Conceptual Problems

**Key:** These problems are designed to check your understanding of the concepts associated with some of the main topics presented in each chapter. A strong conceptual understanding of chemistry is the foundation for both applying chemical knowledge and solving chemical problems. These problems vary in level of difficulty and often can be used as a basis for group discussion.

- 21.71** When producing coke, why is the coal heated in the absence of air? Write the chemical reaction for what would happen if it were to be heated in air.
- 21.72** Even though hydrogen isn't a metal, why is it in Group 1A of most periodic tables?
- 21.73** What happens to the metallic character of the main-group elements as you move left to right across any row of the periodic table? What happens to the metallic character of the main-group elements as you move down a column (group)?
- 21.74** Lithium hydroxide, like sodium hydroxide, becomes contaminated when exposed to air. What is the source of this contamination? What reactions take place?

- 21.75** Aluminum hydroxide is an amphoteric substance. What does this mean? Write equations to illustrate.
- 21.76** Tin metal would not make a very good structural metal in cold climates. Why?
- 21.77** Oxygen, like other second-period elements, is somewhat different from the other elements in its group. List some of these differences.
- 21.78** Given that the reaction Cl<sub>2</sub>(g) + 2KBr(aq) → 2KCl(aq) + Br<sub>2</sub>(aq) readily occurs, would you expect the reaction I<sub>2</sub>(s) + 2KCl(aq) → 2KI(aq) + Cl<sub>2</sub>(aq) to occur?
- 21.79** Hydrogen chloride can be prepared by heating NaCl with concentrated sulfuric acid. Why is substituting NaBr for NaCl in this reaction not a satisfactory way to prepare HBr?
- 21.80** Do you expect an aqueous solution of sodium hypochlorite to be acidic, neutral, or basic? What about an aqueous solution of sodium perchlorate?

## Practice Problems

**Key:** These problems are for practice in applying problem-solving skills. They are divided by topic, and some are keyed to exercises (see the ends of the exercises). The problems are arranged in matching pairs; the odd-numbered problem of each pair is listed first, and its answer is given in the back of the book.

### Metallurgy

**21.81** Pure iron is prepared for special purposes by precipitating iron(III) oxide and reducing the dry oxide with hydrogen gas. Write the balanced equation for this reduction of iron(III) oxide.

**21.82** Manganese is available from its ore pyrolusite, which is manganese(IV) oxide,  $\text{MnO}_2$ . Some manganese metal is prepared from  $\text{MnO}_2$  by reduction with aluminum metal. Write the balanced equation for this reduction.

**21.83** How many kilograms of iron can be produced from 2.00 kg of hydrogen,  $\text{H}_2$ , when you reduce iron(III) oxide? (See Problem 21.81.)

**21.84** How many kilograms of manganese can be produced from 2.50 kg of aluminum, Al, when you reduce manganese(IV) oxide? (See Problem 21.82.)

**21.85** Using thermodynamic data given in Appendix C, obtain  $\Delta H^\circ$  for the roasting of galena, PbS:

Is the reaction endothermic or exothermic?

**21.86** Using thermodynamic data given in Appendix C, obtain  $\Delta H^\circ$  for the reduction of wustite,  $\text{FeO}$ , by aluminum.  $3\text{FeO}(s) + 2\text{Al}(s) \longrightarrow 3\text{Fe}(s) + \text{Al}_2\text{O}_3(s)$ . Is this reaction endothermic or exothermic?

### Bonding in Metals

**21.87** Sketch a diagram showing the formation of energy levels from the valence orbitals for K,  $\text{K}_2$ ,  $\text{K}_3$ , and  $\text{K}_n$ . On the diagram, place arrows indicating how the electrons fill these energy levels.

**21.88** Sketch a diagram showing the formation of energy levels from the valence orbitals for Ca,  $\text{Ca}_2$ ,  $\text{Ca}_3$ , and  $\text{Ca}_n$ . On the diagram, place arrows indicating how the electrons fill these energy levels.

**21.89** How many energy levels are there in the valence band of a single crystal of sodium with a mass of 2.50 mg?

**21.90** How many energy levels are there in the  $3p$  band of a single crystal of magnesium with a mass of 1.10 mg?

### Group 1A: The Alkali Metals

**21.91** Caustic soda, NaOH, can be manufactured from sodium carbonate in a manner similar to the preparation of lithium hydroxide. Write balanced equations (in three steps) for the preparation of NaOH from slaked lime,  $\text{Ca}(\text{OH})_2$ , salt (NaCl), carbon dioxide, ammonia, and water.

**21.92** Sodium phosphate,  $\text{Na}_3\text{PO}_4$ , is produced by the neutralization reaction. Phosphoric acid,  $\text{H}_3\text{PO}_4$ , is obtained

by burning phosphorus to  $\text{P}_4\text{O}_{10}$ , then reacting the oxide with water to give the acid. Write balanced equations (in four steps) for the preparation of  $\text{Na}_3\text{PO}_4$  from  $\text{P}_4$ ,  $\text{H}_2\text{O}$ , air, and NaCl.

**21.93** Complete and balance the following equations.

- $\text{K}(s) + \text{Br}_2(l) \longrightarrow$
- $\text{K}(s) + \text{H}_2\text{O}(l) \longrightarrow$
- $\text{NaOH}(s) + \text{CO}_2(g) \longrightarrow$
- $\text{Li}_2\text{CO}_3(aq) + \text{HNO}_3(aq) \longrightarrow$
- $\text{K}_2\text{SO}_4(aq) + \text{Pb}(\text{NO}_3)_2(aq) \longrightarrow$

**21.94** Complete and balance the following equations.

- $\text{LiHCO}_3(s) \xrightarrow{\Delta}$
- $\text{Na}_2\text{SO}_4(aq) + \text{BaCl}_2(aq) \longrightarrow$
- $\text{K}_2\text{CO}_3(aq) + \text{Ca}(\text{OH})_2(aq) \longrightarrow$
- $\text{Li}(s) + \text{HCl}(aq) \longrightarrow$
- $\text{Na}(s) + \text{ZrCl}_4(g) \longrightarrow$

**21.95** Francium was discovered as a minor decay product of actinium-227. Write the nuclear equation for the decay of actinium-227 by alpha emission.

**21.96** Francium-223 is a radioactive alkali metal that decays by beta emission. Write the nuclear equation for this decay process.

### Group 2A: The Alkaline Earth Metals

**21.97** Sodium hydroxide and calcium hydroxide are strong bases. What simple chemical test could you use to distinguish between solutions of these two bases?

**21.98** Potassium hydroxide and barium hydroxide are strong bases. What simple chemical test could you use to distinguish between solutions of these two bases?

**21.99** Devise a chemical method for separating a solution containing  $\text{MgCl}_2$  and  $\text{BaCl}_2$  to give two solutions or compounds each containing only one of the metal ions.

**21.100** Devise a chemical method for separating a solution containing NaCl and  $\text{MgCl}_2$  to give two solutions or compounds each containing only one of the metal ions.

**21.101** Thorium-230, which occurs in uranium minerals, decays by alpha emission to radium. Write the nuclear equation for this decay process.

**21.102** A short-lived isotope of radium decays by alpha emission to radon-219. Write the nuclear equation for this decay process.

**21.103** Complete and balance the following equations.

- $\text{BaCO}_3(s) \xrightarrow{\Delta}$
- $\text{Ba}(s) + \text{H}_2\text{O}(l) \longrightarrow$
- $\text{Mg}(\text{OH})_2(s) + \text{HNO}_3(aq) \longrightarrow$
- $\text{Mg}(s) + \text{NiCl}_2(aq) \longrightarrow$
- $\text{NaOH}(aq) + \text{MgSO}_4(aq) \longrightarrow$

**21.104** Complete and balance the following equations.

- $\text{KOH}(aq) + \text{MgCl}_2(aq) \longrightarrow$
- $\text{Mg}(s) + \text{CuSO}_4(aq) \longrightarrow$
- $\text{Sr}(s) + \text{H}_2\text{O}(l) \longrightarrow$
- $\text{SrCO}_3(s) + \text{HCl}(aq) \longrightarrow$
- $\text{Ba}(\text{OH})_2(aq) + \text{CO}_2(g) \longrightarrow$

**21.105** You have a 0.19 *M* solution of calcium hydrogen carbonate. How many grams of calcium hydroxide must be added to 25.0 mL of the solution to precipitate all of the calcium?

**21.106** You have a 0.28 *M* solution of magnesium ion. How many grams of calcium hydroxide must be added to 52.5 mL of the solution to precipitate all of the magnesium ion?

### Group 3A and Group 4A Metals

**21.107** Baking powders contain sodium (or potassium) hydrogen carbonate and an acidic substance. When water is added to a baking powder, carbon dioxide is released. One kind of baking powder contains  $\text{NaHCO}_3$  and sodium aluminum sulfate,  $\text{NaAl}(\text{SO}_4)_2$ . Write the net ionic equation for the reaction that occurs in water solution.

**21.108** When aluminum sulfate is dissolved in water, it produces an acidic solution. Suppose the pH of this solution is raised by the dropwise addition of aqueous sodium hydroxide. **a** Describe what you would observe as the pH continues to rise. **b** Write balanced equations for any reactions that occur.

**21.109** The following solid substances are in separate but unlabeled test tubes:  $\text{Al}_2(\text{SO}_4)_3 \cdot 18\text{H}_2\text{O}$ ,  $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$ ,  $\text{KOH}$ . Describe how you could identify the compounds by chemical tests using only these substances and water.

**21.110** Unlabeled test tubes contain solid  $\text{AlCl}_3 \cdot 6\text{H}_2\text{O}$  in one,  $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$  in another, and  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$  in the other. How could you find out what is in each test tube, using chemical tests that involve only these compounds plus water?

**21.111** The  $\text{Sn}^{2+}(\text{aq})$  ion can be written in more detail as  $\text{Sn}(\text{H}_2\text{O})_6^{2+}$ . This ion is acidic by hydrolysis. Write a possible equation for this hydrolysis.

**21.112** Lead(II) nitrate, one of the few soluble lead salts, gives a solution with a pH of about 3 to 4. Write a chemical equation to explain why the solution is acidic.

**21.113** Lead(IV) oxide is a strong oxidizing agent. For example, lead(IV) oxide will oxidize hydrochloric acid to chlorine,  $\text{Cl}_2$ . Write the balanced equation for this reaction.

**21.114** Lead(IV) oxide can be prepared by oxidizing plumbite ion,  $\text{Pb}(\text{OH})_3^-$ , which exists in a basic solution of  $\text{Pb}^{2+}$ . Write the balanced equation for this oxidation by  $\text{OCl}^-$  in basic solution.

**21.115** Complete and balance the following equations.

- a**  $\text{Al}_2\text{O}_3(\text{s}) + \text{H}_2\text{SO}_4(\text{aq}) \longrightarrow$
- b**  $\text{Al}(\text{s}) + \text{AgNO}_3(\text{aq}) \longrightarrow$
- c**  $\text{Pb}(\text{NO}_3)_2(\text{aq}) + \text{NaI}(\text{aq}) \longrightarrow$
- d**  $\text{Al}(\text{s}) + \text{Mn}_3\text{O}_4(\text{s}) \longrightarrow$
- e**  $\text{Ga}(\text{OH})_3(\text{s}) \xrightarrow{\Delta}$

**21.116** Complete and balance the following equations.

- a**  $\text{Pb}(\text{NO}_3)_2(\text{aq}) + \text{Al}(\text{s}) \longrightarrow$
- b**  $\text{Pb}(\text{NO}_3)_2(\text{aq}) + \text{Na}_2\text{CrO}_4(\text{aq}) \longrightarrow$
- c**  $\text{Al}_2(\text{SO}_4)_3(\text{aq}) + \text{dilute LiOH}(\text{aq}) \longrightarrow$
- d**  $\text{Al}(\text{s}) + \text{HCl}(\text{aq}) \longrightarrow$
- e**  $\text{Sn}(\text{s}) + \text{HBr}(\text{aq}) \longrightarrow$

### Hydrogen

**21.117** Calculate the amount of heat evolved when  $3.5 \times 10^4$  kg of hydrogen is combusted.

**21.118** How much heat will be evolved when 22.7 grams of the binary covalent hydride HF is produced via the following reaction?

**21.119** Indicate the oxidation state for the element noted in each of the following:

- a** H in  $\text{CaH}_2$
- b** H in  $\text{H}_2\text{O}$
- c** C in  $\text{CH}_4$
- d** S in  $\text{H}_2\text{SO}_4$

**21.120** Indicate the oxidation state for the element noted in each of the following:

- a** H in  $\text{H}_2$
- b** H in  $\text{C}_2\text{H}_4$
- c** Si in  $\text{SiH}_4$
- d** N in  $\text{HNO}_3$

### Group 4A: The Carbon Family

**21.121** Describe the bonding (using valence bond theory) of the Group 4A atoms in each of the following:

- a**  $\text{C}_2\text{H}_6$
- b**  $\text{AsF}_3$
- c**  $\text{CH}_3\text{CH}=\text{CH}_2$
- d**  $\text{SiH}_4$

**21.122** Describe the bonding (using valence bond theory) of the Group 4A atoms in each of the following:

- a**  $\text{CCl}_4$
- b**  $\text{HCN}$
- c**  $\text{SiF}_4$
- d**  $\text{CH}_3\text{COOH}$  (acetic acid)

**21.123** Calculate the standard enthalpy change for the following “cracking” reactions.

- a**  $\text{CH}_4(\text{g}) \longrightarrow \text{C}(\text{graphite}) + 2\text{H}_2(\text{g})$
- b**  $\text{C}_2\text{H}_6(\text{g}) \longrightarrow \text{C}_2\text{H}_4(\text{g}) + \text{H}_2(\text{g})$

**21.124** Calculate the standard enthalpy change for the following reactions involving synthesis gas.

- a**  $\text{CO}(\text{g}) + 2\text{H}_2(\text{g}) \longrightarrow \text{CH}_3\text{OH}(\text{g})$
- b**  $\text{CO}(\text{g}) + 3\text{H}_2(\text{g}) \longrightarrow \text{CH}_4(\text{g}) + \text{H}_2\text{O}(\text{g})$

**21.125** Complete and balance the following equations.

- a**  $\text{CO}_2(\text{g}) + \text{Ba}(\text{OH})_2(\text{aq}) \longrightarrow$
- b**  $\text{MgCO}_3(\text{s}) + \text{HBr}(\text{aq}) \longrightarrow$

**21.126** Complete and balance the following equations.

- a**  $\text{NaHCO}_3(\text{aq}) + \text{HC}_2\text{H}_3\text{O}_2(\text{aq}) \longrightarrow$
- b**  $\text{Ca}(\text{HCO}_3)_2(\text{aq}) + \text{Ca}(\text{OH})_2(\text{aq}) \longrightarrow$

**21.127** Use balanced equations to show how you could prepare  $\text{Na}_2\text{CO}_3$  from carbon,  $\text{NaOH}$ , air, and  $\text{H}_2\text{O}$ .

**21.128** Use balanced equations to show how you could prepare methanol,  $\text{CH}_3\text{OH}$ , from ethane,  $\text{C}_2\text{H}_6$ , and water.

**21.129** Silicon has a diamond-like structure, with each Si atom bonded to four other Si atoms. Describe the bonding in silicon in terms of hybrid orbitals.

**21.130** Silicon carbide,  $\text{SiC}$ , has a structure in which each Si atom is bonded to four C atoms, and each C atom is bonded to four Si atoms. Describe the bonding in terms of hybrid orbitals.

**21.131** Silicon is prepared by reducing silicon dioxide with carbon at high temperature. How many kilograms of silicon dioxide are required to prepare 5.00 kg of silicon?

**21.132** Silicon is purified by first converting it to silicon tetrachloride, which is then distilled. How many kilograms of silicon are required to prepare 5.70 kg of  $\text{SiCl}_4$ ?

**21.133** Draw a portion of the structure of the mineral spodumene,  $\text{LiAl}(\text{SiO}_3)_2$ , which is a mineral consisting of a long chain of  $\text{SiO}_4$  tetrahedra. Use this drawing to verify the empirical formula given.

**21.134** Draw a portion of the structure of the mineral beryl,  $\text{Be}_3\text{Al}_2(\text{SiO}_3)_6$ , which is a mineral consisting of cyclic silicate anions. Use this drawing to verify the empirical formula given.

### Group 5A: Nitrogen and the Phosphorus Family

**21.135** Magnesium nitride,  $\text{Mg}_3\text{N}_2$ , reacts with water to produce magnesium hydroxide and ammonia. How many grams of ammonia can you obtain from 7.50 g of magnesium nitride?

**21.136** Ammonia reacts with oxygen in the presence of a platinum catalyst to give nitric oxide,  $\text{NO}$ . How many grams of oxygen are required in this reaction to give 3.10 g  $\text{NO}$ ?

**21.137** You have the following substances:  $\text{NH}_3$ ,  $\text{O}_2$ , Pt, and  $\text{H}_2\text{O}$ . Write equations for the preparation of  $\text{N}_2\text{O}$  from these substances.

**21.138** Give equations for the preparation of  $\text{N}_2\text{O}$ . You can use  $\text{NaOH}$ ,  $\text{NaNO}_3$ ,  $\text{H}_2\text{SO}_4$ , and  $(\text{NH}_4)_2\text{SO}_4$  (plus  $\text{H}_2\text{O}$ ). Several steps are required.

**21.139** Zinc metal reacts with concentrated nitric acid to give zinc ion and ammonium ion. Write the balanced equation for this reaction.

**21.140** Silver metal reacts with nitric acid to give silver ion and nitric oxide. Write the balanced equation for this reaction.

**21.141** Although phosphorus pentabromide exists in the vapor phase as  $\text{PBr}_5$  molecules, in the solid phase the substance is ionic and has the structure  $[\text{PBr}_4^+]\text{Br}^-$ . What is the expected geometry of  $\text{PBr}_4^+$ ? Describe the bonding to phosphorus in  $\text{PBr}_4^+$ .

**21.142** Although phosphorus pentachloride exists in the vapor phase as  $\text{PCl}_5$  molecules, in the solid phase the substance is ionic and has the structure  $[\text{PCl}_4^+][\text{PCl}_6^-]$ . What is the expected geometry of  $\text{PCl}_6^-$ ?

**21.143** Phosphorous acid,  $\text{H}_3\text{PO}_3$ , is oxidized to phosphoric acid,  $\text{H}_3\text{PO}_4$ , by hot, concentrated sulfuric acid, which is reduced to  $\text{SO}_2$ . Write the balanced equation for this reaction.

**21.144** Phosphorous acid,  $\text{H}_3\text{PO}_3$ , is oxidized to phosphoric acid,  $\text{H}_3\text{PO}_4$ , by nitric acid, which is reduced to nitrogen monoxide,  $\text{NO}$ . Write the balanced equation for this reaction.

**21.145** According to an analysis, a sample of phosphate rock contains 74.6%  $\text{Ca}_3(\text{PO}_4)_2$ , by mass. How many grams

of phosphoric acid,  $\text{H}_3\text{PO}_4$ , can be obtained from 55.0 g of the phosphate rock according to the following reaction?

**21.146** According to an analysis, a sample of phosphate rock contains 73.7%  $\text{Ca}_3(\text{PO}_4)_2$ , by mass. How many grams of calcium dihydrogen phosphate,  $\text{Ca}(\text{H}_2\text{PO}_4)_2$ , can be obtained from 10.1 g of phosphate rock from the following reaction?

### Group 6A: Oxygen and the Sulfur Family

**21.147** Write an equation for each of the following.

- a burning of lithium metal in oxygen
- b burning of methylamine,  $\text{CH}_3\text{NH}_2$ , in excess oxygen (N ends up as  $\text{N}_2$ )
- c burning of diethyl sulfide,  $(\text{C}_2\text{H}_5)_2\text{S}$ , in excess oxygen

**21.148** Write an equation for each of the following.

- a burning of calcium metal in oxygen
- b burning of phosphine,  $\text{PH}_3$ , in excess oxygen
- c burning of ethanamine,  $\text{HOCH}_2\text{CH}_2\text{NH}_2$ , in excess oxygen (N ends up as  $\text{N}_2$ )

**21.149** What are the oxidation numbers of sulfur in each of the following?

- a  $\text{SF}_6$
- b  $\text{SO}_3$
- c  $\text{H}_2\text{S}$
- d  $\text{CaSO}_3$

**21.150** What are the oxidation numbers of sulfur in each of the following?

- a  $\text{S}_8$
- b  $\text{CaS}$
- c  $\text{CaSO}_4$
- d  $\text{SCl}_4$

**21.151** Selenous acid,  $\text{H}_2\text{SeO}_3$ , is reduced by  $\text{H}_2\text{S}$  to sulfur,  $\text{S}_8$ , and selenium,  $\text{Se}_8$ . Write the balanced equation for this reaction.

**21.152** Concentrated sulfuric acid oxidizes iodide ion to iodine,  $\text{I}_2$ . Write the balanced equation for this reaction.

**21.153** Sodium hydrogen sulfite is prepared from sodium carbonate and sulfur dioxide:

How many grams of  $\text{NaHSO}_3$  can be obtained from 29.0 g of  $\text{Na}_2\text{CO}_3$ ?

**21.154** Sodium thiosulfate,  $\text{Na}_2\text{S}_2\text{O}_3$ , is prepared from sodium sulfite and sulfur:

How many grams of  $\text{Na}_2\text{S}_2\text{O}_3$  can be obtained from 50.0 g of sulfur?

### Group 7A: The Halogens

**21.155** A solution of chloric acid may be prepared by reacting a solution of barium chlorate with sulfuric acid. Barium sulfate precipitates. Write the balanced equation for the reaction.

**21.156** A solution of chlorous acid may be prepared by reacting a solution of barium chlorite with sulfuric acid. Barium sulfate precipitates. Write the balanced equation for the reaction.

**21.157** Chlorine can be prepared by oxidizing chloride ion (from hydrochloric acid) with potassium dichromate,  $K_2Cr_2O_7$ , which is reduced to  $Cr^{3+}$ . Write the balanced equation for the reaction.

**21.158** Iodic acid,  $HIO_3$ , can be prepared by oxidizing elemental iodine with concentrated nitric acid, which is reduced to nitrogen dioxide,  $NO_2(g)$ . Write the balanced equation for the reaction.

**21.159** Discuss the bonding in each of the following molecules or ions. What is the expected molecular geometry?

- a**  $Cl_2O$       **b**  $BrO_3^-$       **c**  $BCl_3$

**21.160** Discuss the bonding in each of the following molecules or ions. What is the expected molecular geometry?

- a**  $HClO$       **b**  $ClO_4^-$       **c**  $BaF_2$

**21.161** Write balanced equations for each of the following.

**a** Bromine reacts with aqueous sodium hydroxide to give hypobromite and bromide ions.

**b** Hydrogen bromide gas forms when sodium bromide is heated with phosphoric acid.

**21.162** Write balanced equations for each of the following.

**a** Solid calcium fluoride is heated with sulfuric acid to give hydrogen fluoride vapor.

**b** Solid potassium chlorate is carefully heated to yield potassium chloride and potassium perchlorate.

**21.163** By calculating the standard emf, decide whether aqueous sodium hypochlorite solution will oxidize  $Fe^{2+}(aq)$  to  $Fe^{3+}(aq)$  in basic solution under standard conditions. See Appendix I for data.

**21.164** Using standard electrode potentials, decide whether aqueous sodium hypochlorite solution will oxidize  $Br^-$  to  $Br_2$  in basic solution under standard conditions. See Appendix I for data.

### Group 8A: The Noble Gases

**21.165** Xenon tetrafluoride,  $XeF_4$ , is a colorless solid. Give the Lewis formula for the  $XeF_4$  molecule. What geometry is predicted by the VSEPR model for this molecule?

**21.166** Xenon tetroxide,  $XeO_4$ , is a colorless, unstable gas. Give the Lewis formula for the  $XeO_4$  molecule. What geometry would you expect for this molecule?

**21.167** Xenon difluoride,  $XeF_2$ , is hydrolyzed (broken up by water) in basic solution to give xenon, fluoride ion, and  $O_2$  as products. Write a balanced equation for the reaction.

**21.168** Xenon trioxide,  $XeO_3$ , is reduced to xenon in acidic solution by iodide ion. Iodide ion is oxidized to iodine,  $I_2$ . Write a balanced chemical equation for the reaction.

## General Problems

**Key:** These problems provide more practice but are not divided by topic or keyed to exercises. Each section ends with essay questions, each of which is color coded to refer to the *A Chemist Looks at Materials* (brown) chapter essay on which it is based. Odd-numbered problems and the even-numbered problems that follow are similar; answers to all odd-numbered problems except the essay questions are given in the back of the book.

**21.169** A sample of zinc ore contains 87.0% sphalerite,  $ZnS$ . How many metric tons of Zn can be obtained from 1.00 metric ton of the zinc ore?

**21.170** A sample of lead ore contains 78.0% galena,  $PbS$ . How many metric tons of Pb can be obtained from 1.00 metric ton of the lead ore?

**21.171** A 50.00-mL volume of 0.4987 M HCl was added to a 5.436-g sample of milk of magnesia. This solution was then titrated with 0.2456 M NaOH. If it required 39.42 mL of NaOH to reach the endpoint, what was the mass percentage of  $Mg(OH)_2$  in the milk of magnesia?

**21.172** An antacid tablet consists of calcium carbonate with other ingredients. The calcium carbonate in a 0.9863-g sample of the antacid was dissolved in 50.00 mL of 0.5068 M HCl, then titrated with 41.23 mL of 0.2590 M NaOH. What was the mass percentage of  $CaCO_3$  in the antacid?

**21.173** Calculate the standard enthalpy change,  $\Delta H^\circ$ , for the following reaction at 25°C.

What is the enthalpy change per mole of iron?

**21.174** Calculate the standard enthalpy change,  $\Delta H^\circ$ , for the following reaction at 25°C.

What is the enthalpy change per mole of calcium?

**21.175** A sample of limestone was dissolved in hydrochloric acid, and the carbon dioxide gas that evolved was collected. If a 0.1662-g sample of limestone gave 34.56 mL of dry carbon dioxide gas at 745 mmHg and 21°C, what was the mass percentage of  $CaCO_3$  in the limestone?

**21.176** A sample of rock containing magnesite,  $MgCO_3$ , was dissolved in hydrochloric acid, and the carbon dioxide gas that evolved was collected. If a 0.1504-g sample of the rock gave 37.71 mL of dry carbon dioxide gas at 758 mmHg and 22°C, what was the mass percentage of  $MgCO_3$  in the rock?

**21.177** How many grams of sodium chloride are required to produce 10.00 g of  $NaHCO_3$  by the Solvay process?

**21.178** How many grams of aluminum are required to react with 15.00 g of chromium(III) oxide by the Goldschmidt process for the production of chromium metal?

**21.179** Estimate the temperature at which strontium carbonate begins to decompose to strontium oxide and  $CO_2$  at 1 atm.

Use thermodynamic data in Appendix C.

**21.180** Estimate the temperature at which barium carbonate decomposes to barium oxide and  $CO_2$  at 1 atm.

Use thermodynamic data in Appendix C.

**21.181** Calculate  $E^\circ$  for the disproportionation of  $\text{In}^+(aq)$ .

(Disproportionation is a reaction in which a species undergoes both oxidation and reduction.) Use the following standard potentials:

From  $E^\circ$ , calculate  $\Delta G^\circ$  for the disproportionation (in kilojoules). Does this reaction occur spontaneously?

**21.182** Calculate  $E^\circ$  for the disproportionation of  $\text{Tl}^+(aq)$ .

(Disproportionation is a reaction in which a species undergoes both oxidation and reduction.) Use the following standard potentials:

From  $E^\circ$ , calculate  $\Delta G^\circ$  for the disproportionation (in kilojoules). Does this reaction occur spontaneously?

**21.183** Lithium hydroxide has been used in spaceships to absorb carbon dioxide exhaled by astronauts. Assuming that the product is lithium carbonate, determine what mass of lithium hydroxide is needed to absorb the carbon dioxide from 1.00 L of air containing 30.0 mmHg partial pressure of  $\text{CO}_2$  at  $25^\circ\text{C}$ .

**21.184** Potassium chlorate,  $\text{KClO}_3$ , is used in fireworks and explosives. It can be prepared by bubbling chlorine into hot aqueous potassium hydroxide;  $\text{KCl}(aq)$  and  $\text{H}_2\text{O}$  are the other products in the reaction. How many grams of  $\text{KClO}_3$  can be obtained from 138 L of  $\text{Cl}_2$  whose pressure is 784 mmHg at  $25^\circ\text{C}$ ?

**21.185** The main ingredient in many phosphate fertilizers is  $\text{Ca}(\text{H}_2\text{PO}_4)_2 \cdot \text{H}_2\text{O}$ . If a fertilizer is 17.1% P (by mass), and all of this phosphorus is present as  $\text{Ca}(\text{H}_2\text{PO}_4)_2 \cdot \text{H}_2\text{O}$ , what is the mass percentage of this salt in the fertilizer?

**21.186** A fertilizer contains phosphorus in two compounds,  $\text{Ca}(\text{H}_2\text{PO}_4)_2 \cdot \text{H}_2\text{O}$  and  $\text{CaHPO}_4$ . The fertilizer contains 30.0%  $\text{Ca}(\text{H}_2\text{PO}_4)_2 \cdot \text{H}_2\text{O}$  and 10.0%  $\text{CaHPO}_4$  (by mass). What is the mass percentage of phosphorus in the fertilizer?

**21.187**  $\text{NaClO}$  solution is made by electrolysis of  $\text{NaCl}(aq)$  by allowing the products  $\text{NaOH}$  and  $\text{Cl}_2$  to mix. How long

must a cell operate to produce  $1.00 \times 10^3$  L of 5.25%  $\text{NaClO}$  solution (density = 1.00 g/mL) if the cell current is  $3.00 \times 10^3$  A?

**21.188** Sodium perchlorate,  $\text{NaClO}_4$ , is produced by electrolysis of sodium chlorate,  $\text{NaClO}_3$ . If a current of  $2.50 \times 10^3$  A passes through an electrolytic cell, how many kilograms of sodium perchlorate are produced per hour?

**21.189** The amount of sodium hypochlorite in a bleach solution can be determined by using a given volume of bleach to oxidize excess iodide ion to iodine, because the reaction goes to completion. The amount of iodine produced is then determined by titration with sodium thiosulfate,  $\text{Na}_2\text{S}_2\text{O}_3$ , which is oxidized to sodium tetrathionate,  $\text{Na}_2\text{S}_4\text{O}_6$ . Potassium iodide was added in excess to 5.00 mL of bleach (density = 1.00 g/mL). This solution, containing the iodine released in the reaction, was titrated with 0.100 M  $\text{Na}_2\text{S}_2\text{O}_3$ . If 34.6 mL of sodium thiosulfate was required to reach the endpoint (detected by disappearance of the blue color of the starch-iodine complex), what was the mass percentage of  $\text{NaClO}$  in the bleach?

**21.190** Ascorbic acid,  $\text{C}_6\text{H}_8\text{O}_6$  (vitamin C), is a reducing agent. The amount of this acid in solution can be determined quantitatively by a titration procedure involving iodine,  $\text{I}_2$ , in which ascorbic acid is oxidized to dehydroascorbic acid,  $\text{C}_6\text{H}_6\text{O}_6$ .

A 30.0-g sample of an orange-flavored beverage mix was placed in a flask to which 10.00 mL of 0.0500 M  $\text{KIO}_3$  and excess  $\text{KI}$  were added. The  $\text{IO}_3^-$  and  $\text{I}^-$  ions react in acid solution to give  $\text{I}_2$ , which then reacts with ascorbic acid. Excess iodine is titrated with sodium thiosulfate (see Problem 21.189). If 31.2 mL of 0.0300 M  $\text{Na}_2\text{S}_2\text{O}_3$  is required to titrate the excess  $\text{I}_2$ , how many grams of ascorbic acid are there in 100.0 g of beverage mix?

■ **21.191** What is a superconductor? What is one use of superconductors?

■ **21.192** In 1986, Bernorz and Müller received the Nobel Prize in physics for what discovery? Why was this discovery important?

■ **21.193** How was the molecule  $\text{C}_{60}$  first discovered? Describe the experiment in some detail.

■ **21.194** What makes  $\text{C}_{60}$  such a stable molecule? What shape does the molecule have?

## Strategy Problems

**Key:** As noted earlier, all of the practice and general problems are matched pairs. This section is a selection of problems that are not in matched-pair format. These challenging problems require that you employ many of the concepts and strategies that were developed in the chapter. In some cases, you will have to integrate several concepts and operational skills in order to solve the problem successfully.

**21.195** A 0.325-g sample of sulfur was burned in an excess of oxygen in the presence of a platinum catalyst. The final product of this combustion was then dissolved in water to give 1.000 L of solution. To this solution was

added 75.6 mL of 0.1028 M aqueous  $\text{BaCl}_2$ , resulting in a white precipitate. This precipitate was filtered off, dried, and weighed. What was the product of the combustion of sulfur in excess oxygen? What was the solution obtained by dissolving this product in water? What was the white precipitate? What was the mass of this dried precipitate?

**21.196**

a Nitrogen dioxide can be prepared by heating lead nitrate to about  $400^\circ\text{C}$ . The products, in addition to nitrogen dioxide, are lead(II) oxide and oxygen. Write the equation for this decomposition.

**b** Nitrogen dioxide gas is always in equilibrium with dinitrogen tetroxide gas. Write the chemical equation for this equilibrium.

**c** A sample of an equilibrium mixture of these gases at 738 mmHg and 25°C weighing 1.427 g had a volume of 456 mL. According to these data, what is the value of  $K_p$  for the equilibrium of nitrogen dioxide going to dinitrogen tetroxide?

**21.197** Sulfur is formed in volcanic gases when sulfur dioxide reacts with hydrogen sulfide. The same reaction has been proposed as a method of removing sulfur dioxide from the gases emitted from coal-fired electricity generation plants. The emitted gases, containing sulfur dioxide, are bubbled through an aqueous solution of hydrogen sulfide.

**a** Write the balanced chemical equation for the reaction of sulfur dioxide gas with hydrogen sulfide gas to produce solid sulfur and water vapor.

**b** Suppose 5.00 L of sulfur dioxide at 748 mmHg and 22°C reacts with 15.1 g of hydrogen sulfide. How many grams of sulfur would be produced?

**21.198** Use thermodynamic data to calculate the standard enthalpy change for the decomposition of water vapor to atoms in the gas phase. From this, obtain a value for the O—H bond enthalpy. Similarly, obtain the standard enthalpy change for the decomposition of hydrogen peroxide vapor to atoms in the gas phase. Then, using the value you found for the O—H bond enthalpy, obtain a value for the O—O bond enthalpy. Compare these values with those listed in Table 9.5.

**21.199** A sample of a metal sulfide weighing 6.125 g was roasted in air to obtain 5.714 g of the oxide. The oxide was then dissolved in dilute sulfuric acid, which yielded a white precipitate. The mass of the dry precipitate was 7.763 g.

**a** Show that these data are consistent with the precipitate being a sulfate.

**b** From this information, decide what metal or metals are consistent with the information given. Justify your answer.

**21.200** A mixture contained aluminum sulfate and sodium sulfate. A sample of the mixture weighing 3.458 g

was dissolved in water and treated with sodium hydroxide solution to yield a precipitate. The precipitate was incinerated to yield 0.474 g aluminum oxide. Write chemical equations for the reactions that occur. Calculate the percentage of aluminum sulfate in the mixture.

**21.201** A quantity of white phosphorus was burned in an excess of oxygen. The product of this combustion was dissolved in water to give 1.258 L of solution. This solution was found to have a pH of 2.091.

**a** Write the equation for the combustion.

**b** What was the mass of the white phosphorus?

**c** The solution was treated with a solution of calcium nitrate, yielding a white precipitate. Write the chemical equation for this precipitation reaction.

**d** Assuming that sufficient calcium nitrate was added to give complete reaction, what was the mass of precipitate obtained?

**21.202** A white crystalline material contained sodium acetate and sodium chloride. To determine the composition of this mixture, a researcher dissolved 0.613 g of this mixture in water to give 25.0 mL of solution. She then determined that the pH of this solution was 9.03. What was the percentage of sodium acetate in the mixture, assuming that it contained only sodium chloride and sodium acetate?

**21.203** When carbon burns in air, carbon dioxide is a product. Carbon monoxide can also be present in this combustion because it is the product of the reaction of carbon dioxide with hot carbon. Write the chemical equation for this production of carbon monoxide. Using thermodynamic data and any reasonable approximations, obtain the equilibrium constant for this reaction at 2000°C. Assume the carbon is in the form of graphite.

**21.204** Write the chemical equation for the reaction of iron metal with hydrochloric acid. Similarly, write the chemical equation for the reaction of copper metal with nitric acid. Discuss the difference between copper and iron metals in reacting with dilute hydrochloric acid and with dilute nitric acid. Use electrode potentials in your discussion.

## 22

# The Transition Elements and Coordination Compounds

Heating the red cobalt(III) complex  $[\text{Co}(\text{NH}_3)_5\text{H}_2\text{O}]\text{Cl}_3(s)$  drives off the water molecule, forming the purple complex  $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2(s)$ . Similarly, complexes of cobalt(II) undergo color changes with hydration or dehydration. The complex  $[\text{CoCl}_2(\text{H}_2\text{O})_2]$  is used in humidity indicator cards. It is blue, but picks up water molecules in a humid atmosphere to form the pink complex  $[\text{Co}(\text{H}_2\text{O})_6]\text{Cl}_2$ .

## CONTENTS AND CONCEPTS

### Properties of the Transition Elements

The *transition elements* have diverse and interesting chemistry, which we will investigate in this section.

**22.1** Periodic Trends in the Transition Elements

**22.2** The Chemistry of Two Transition Elements

### Complex Ions and Coordination Compounds

Transition elements can form a distinct set of substances (often highly colored) from *complex ions* called *coordination compounds*.

**22.3** Formation and Structure of Complexes

**22.4** Naming Coordination Compounds

**22.5** Structure and Isomerism in Coordination Compounds

**22.6** Valence Bond Theory of Complexes

**22.7** Crystal Field Theory

In the previous chapter, we studied the main-group elements—the A groups in the periodic table. Between columns 2A and 3A are ten columns of the transition elements—the B groups. Among these elements are metals with familiar commercial applications: iron tools, copper wire, silver jewelry, and coins. Many catalysts for important industrial reactions involve transition elements. Examples of these are found in petroleum refining and in the synthesis of ammonia from  $N_2$  and  $H_2$ .

In addition to their commercial usefulness, many transition elements have biological importance. Iron compounds, for example, are found throughout the plant and animal kingdoms. Iron is present in hemoglobin, the molecule in red blood cells that is responsible for the transport of oxygen,  $O_2$ , from the lungs to other body tissue. Myoglobin, found in muscle tissue, is a similar molecule containing iron. Myoglobin takes oxygen from hemoglobin, holding it until it is required by the muscle cells. Cytochromes, iron-containing compounds within each cell, are involved in the oxidation of food molecules. In these cases, the transition element is central to the structure and function of the biological molecule. Hemoglobin and myoglobin are examples of *metal complexes*, or *coordination compounds*, in which the metal atom is surrounded by other atoms bonded to it by the electron pairs these atoms donate. In hemoglobin and myoglobin, the  $O_2$  molecule bonds to the iron atom.

We will look at the general properties of transition metals in the first section of the chapter; in the second section we will investigate the chemistry of two transition elements, chromium and copper. The remaining sections of the chapter will cover the structure, naming, and bonding of complex ions and coordination compounds.

## ► Properties of the Transition Elements

Often, all of the B elements of the periodic table are classified as transition elements, though strictly speaking, the **transition elements** are defined as *those metallic elements that have an incompletely filled  $d$  subshell or easily give rise to common ions that have incompletely filled  $d$  subshells*. Iron, whose electron configuration is  $[Ar]3d^64s^2$ , is an example of such an element; iron has an incompletely filled  $3d$  subshell. Another example is copper. Although the free element has the configuration  $[Ar]3d^{10}4s^1$ , in which the  $3d$  subshell is complete, copper readily forms the copper(II) ion, whose configuration  $[Ar]3d^9$  has an incomplete  $3d$  subshell. The Group 2B elements zinc, cadmium, and mercury have filled  $d$  subshells in the element and in the common ions, so in the strict sense these are not transition elements, although they are often included with them.

Sometimes, too, chemists include the two rows of elements at the bottom of the periodic table with the transition elements. These two rows, often referred to as the *inner transition elements*, have partially filled  $f$  subshells in common oxidation states. The elements in the first row are called the *lanthanides*, or *rare earths*, and the elements in the second row are called the *actinides*. Figure 22.1 shows the divisions of the transition elements. The B columns of transition elements, as well as the inner transition elements, frequently form complex ions and coordination compounds.

### 22.1 Periodic Trends in the Transition Elements

The transition elements have a number of characteristics that set them apart from the main-group elements:

1. All of the transition elements are metals and, except for the 2B elements, have high melting points and high boiling points and are hard solids. For instance, of the fourth-period elements from scandium to copper, the lowest-melting metal is copper ( $1083^\circ\text{C}$ ) and the highest-melting metal is vanadium ( $1890^\circ\text{C}$ ). Of the main-group metals, only beryllium melts above  $1000^\circ\text{C}$ ; the rest melt at appreciably lower temperatures.

Transition elements  
 Inner transition elements (lanthanides and actinides)

- With the exception of the 3B and 2B elements, every transition element has several oxidation states. Vanadium, for example, exists as aqueous ions in all oxidation states from +2 to +5 (Figure 22.2). Of the main-group metals, only the heavier ones display several oxidation states. Because of their multiplicity of oxidation states, the transition elements are often involved in oxidation–reduction reactions.
- Transition-metal compounds are often colored, and many are paramagnetic. Most compounds of the main-group metals are colorless and diamagnetic.

We will look at points 1 and 2 in some detail in this section. In particular, we will examine trends in melting points, boiling points, hardness, and oxidation states. We will also look at trends in covalent radii and ionization energies, which we can relate to chemical properties. We will discuss the color and paramagnetism of transition-metal complexes later in the chapter.

### Electron Configurations

Electronic structure is central to any discussion of the transition elements. Table 22.1 lists the ground-state electron configurations of the fourth-period transition elements. For the most part, these configurations are predicted by the building-up principle. Following the building-up principle, the  $3d$  subshell begins to fill after calcium (configuration  $[\text{Ar}]4s^2$ ). Thus scandium has the configuration  $[\text{Ar}]3d^14s^2$ , and as you go across the period, additional electrons go into the  $3d$  subshell. You get the configuration  $[\text{Ar}]3d^24s^2$  for titanium and  $[\text{Ar}]3d^34s^2$  for vanadium. Then in chromium the configuration predicted by the building-up principle is  $[\text{Ar}]3d^44s^2$ , but the actual configuration is  $[\text{Ar}]3d^54s^1$ . The configurations for the rest of the elements are those predicted by the building-up principle, until you get to copper. Here, the predicted configuration is  $[\text{Ar}]3d^94s^2$ , but the actual configuration is  $[\text{Ar}]3d^{10}4s^1$ .

### Melting Points and Boiling Points

Table 22.1 reveals that the melting points of the transition metals increase from  $1541^\circ\text{C}$  for scandium to  $1890^\circ\text{C}$  for vanadium and  $1857^\circ\text{C}$  for chromium, then decrease from  $1535^\circ\text{C}$  for iron to  $1083^\circ\text{C}$  for copper and  $420^\circ\text{C}$  for zinc. The same pattern is observed in the fifth-period and sixth-period elements. As you read across a row of transition elements, the melting points increase, reaching a maximum at the Group 5B or 6B elements, after which the melting points decrease. For instance,

tungsten in Group 6B has the highest melting point (3410°C) of all metallic elements, and mercury in Group 2B has the lowest (−39°C). Similar trends can be seen in the boiling points of the metals. These properties depend on the strength of metal bonding, which in turn depends roughly on the number of unpaired electrons in the metal atoms. At the beginning of a period of transition elements, there is one unpaired *d* electron. The number of unpaired *d* electrons increases across a period until Group 6B, after which the electrons begin to pair.

### Atomic Radii

Trends in atomic radii are of concern because chemical properties are determined in part by atomic size. Looking at the fourth-period covalent radii (one measure of atomic size) in Table 22.1, you see that they decrease quickly from scandium (144 pm) to titanium (132 pm) and vanadium (122 pm). This decrease in atomic size across a row is also observed in the main-group elements. It is due to an increase in *effective nuclear charge* that acts on the outer electrons and pulls them in more strongly. The effective nuclear charge is the positive charge “felt” by an electron; it equals the nuclear charge minus the shielding or screening of the positive charge by intervening electrons. After vanadium, the covalent radii decrease slowly from 118 pm for chromium to 115 pm for nickel. Then the covalent radii increase slightly to 117 pm for copper and 125 pm for zinc. ◀ The relative constancy in covalent radii for the later elements is partly responsible for the similarity in properties of the Group 8B elements iron, cobalt, and nickel.

Figure 22.3 compares the covalent radii of the transition elements. The atomic radii increase in going from a fourth-period to a fifth-period element within any column. For example, reading down the Group 3B elements, you find that the covalent radius of scandium is 144 pm and of yttrium is 162 pm. You would expect an increase of radius from scandium to yttrium because of the addition of a shell of electrons. Continuing down the column of 3B elements,

The small increase in covalent radius for copper and zinc has no simple explanation.

you find a small increase of covalent radius to 169 pm in lanthanum. But all of the remaining elements of the sixth period have nearly the same covalent radii as the corresponding elements in the fifth period.

This similarity of radii in the fifth- and sixth-period transition elements can be explained in terms of the *lanthanide contraction*. Between lanthanum and hafnium in the sixth period are 14 lanthanide elements (cerium to lutetium), in which the 4*f* subshell fills. The covalent radius decreases slowly from cerium (165 pm) to lutetium (156 pm), but the total decrease is substantial. By the time the 4*f* subshell is complete, the covalent radii of the transition elements from hafnium on are similar to those of the elements in the preceding row of the periodic table. Therefore, the covalent radius of hafnium (146 pm) is approximately the same as that of zirconium (145 pm).

The chemical properties of the transition elements parallel the pattern seen in covalent radii. That is, the fourth-period elements have substantially different properties from the elements in the same group in the fifth and sixth periods. However, elements in the same group of the fifth and sixth periods are very much alike. Hafnium, for example, is so much like zirconium that it remained undiscovered until it was identified in 1923 in zirconium ores from its X-ray spectrum. ► Zirconium (mixed with hafnium as an impurity) was discovered more than a hundred years earlier, in 1787.

### Ionization Energies

Looking at the first ionization energies of the fourth-period transition elements (Table 22.2), you see that although they vary somewhat irregularly, they tend to increase from left to right. The other rows of transition elements behave similarly. Most noteworthy, however, is that all of the sixth-period elements after lanthanum have ionization energies higher than those of the fourth-period and fifth-period transition elements in the same group. This behavior is opposite to that of the main-group elements, where the ionization energies decrease regularly down a column. The high ionization energies of the sixth-period elements from osmium to mercury are no doubt one determinant of the relative unreactivity of these elements.

### Oxidation States

Table 22.3 gives oxidation states in compounds of the fourth-period transition elements. Scandium occurs as the 3+ ion and zinc as the 2+ ion. The other elements exhibit several oxidation states. This multiplicity of oxidation states is due to the varying involvement of the *d* electrons in bonding.

Figure 22.3 ▲

#### Covalent radii for transition elements of Periods 4 to 6

Note that elements of the fifth and sixth periods of the same column have approximately the same radii.

The atomic number of an atom can be obtained from its X-ray spectrum, which therefore gives unequivocal identification of an element. See the essay at the end of Section 8.2.

Table 22.2 First Ionization Energies of the Transition Elements (kJ/mol)

Period	3B	4B	5B	6B	7B	8B			1B	2B
Fourth	Sc	Ti	V	Cr	Mn	Fe	Co	Ni	Cu	Zn
	631	658	650	652	717	759	758	737	745	906
Fifth	Y	Zr	Nb	Mo	Tc	Ru	Rh	Pd	Ag	Cd

	538	680	761	770	760	840	880	870	890	1007

**Table 22.3** Oxidation States of the Fourth-Period Transition Elements

3B	4B	5B	6B	7B	8B			1B	2B
					Fe	Co	Ni		
							+1	+1	
	+2	+2	<b>+2</b>	<b>+2</b>	<b>+2</b>	<b>+2</b>	<b>+2</b>	<b>+2</b>	<b>+2</b>
<b>+3</b>	+3	<b>+3</b>	<b>+3</b>	+3	<b>+3</b>	<b>+3</b>	+3	+3	
	<b>+4</b>	<b>+4</b>	+4	<b>+4</b>	+4	+4	+4		
		<b>+5</b>	+5	+5	+5				
			<b>+6</b>	+6	+6				
				<b>+7</b>					

*Key:* Common oxidation states are in boldface. Additional oxidation states, particularly zero and negative values, may be observed in complexes with CO and with organic compounds.

Most of the transition elements have a doubly filled  $ns$  orbital. Because the  $ns$  electrons ionize before the  $(n - 1)d$  electrons, you might expect the +2 oxidation state to be common. This oxidation state is in fact seen in all of the fourth-period elements except scandium, where the 3+ ion with an Ar configuration is especially stable.

The maximum oxidation state possible equals the number of  $s$  and  $d$  electrons in the valence shell (which equals the group number for the elements up to iron). Titanium in Group 4B has a maximum oxidation state of +4. Similarly, vanadium (Group 5B), chromium (Group 6B), and manganese (Group 7B) exhibit maximum oxidation states of +5, +6, and +7, respectively. ◀

The total number of oxidation states actually observed increases from scandium (+3) to manganese (all states from +2 to +7). From iron on, however, the maximum oxidation state is not attained, so the number of observed states decreases. The highest oxidation state seen in iron is +6. ◀ Thereafter, the highest observed oxidation number decreases until, for zinc compounds, you find only the +2 oxidation state. The  $Zn^{2+}$  ion has a stable  $[Ar]3d^{10}$  configuration.

The maximum oxidation state is generally found in compounds of the transition elements with very electronegative elements, such as F and O (in oxides and oxoanions).

Presumably, Fe(VIII) would oxidize any element to which it would bond.

## 22.2 The Chemistry of Two Transition Elements

In this section, we look at the chemical properties of two transition elements, chromium and copper. Both elements are well known and commercially important; in addition, they provide many examples of colorful compounds.

### Chromium

A fascinating feature of chromium chemistry is the many colorful compounds of this element. In fact, this feature is the origin of the name *chromium*, which derives from the Greek word *khroma*, meaning “color.” The common oxidation states of chromium in compounds are +2, +3, and +6.

The chromium(II) ion,  $[Cr(H_2O)_6]^{2+}(aq)$ , has a bright blue color. The ion is obtained when an acid, such as  $HCl(aq)$ , reacts with chromium metal (see Figure 22.4, left).

The chromium(II) ion is easily oxidized to chromium(III) ion by  $O_2$  (Figure 22.4, right). Therefore, to prepare chromium(II) salts, we must carry out this reaction in the absence of air.

Chromium metal reacts with hydrochloric acid to produce  $[Cr(H_2O)_6]^{2+}$ , which is blue.

$[Cr(H_2O)_6]^{2+}$  oxidizes with air to give a chromium(III) species, which is green.

© Cengage Learning

**Figure 22.4** ▲  
Aqueous chromium ion

The most common oxidation state of chromium is +3. Chromium metal burns in air to give chromium(III) oxide,  $\text{Cr}_2\text{O}_3$  (also called chromic oxide). This oxide is a dark green solid, which has been used as a paint pigment (chrome green). Chromium(III) oxide dissolves in acid solution to form the violet-colored ion  $[\text{Cr}(\text{H}_2\text{O})_6]^{3+}(\text{aq})$ . (Hydrochloric acid solution, however, yields green-colored complex ions of  $\text{Cr}^{3+}$  with  $\text{Cl}^-$ .) Potassium chromium(III) sulfate (or chrome alum),  $\text{KCr}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ , is a common chromium(III) salt. It is a deep purple compound used for leather tanning.

The +6 oxidation state is represented by the chromate ion,  $\text{CrO}_4^{2-}$ , and the dichromate ion,  $\text{Cr}_2\text{O}_7^{2-}$ . Sodium chromate,  $\text{Na}_2\text{CrO}_4$ , which is yellow, and sodium dichromate,  $\text{Na}_2\text{Cr}_2\text{O}_7$ , which is orange, are the primary sources of compounds of chromium. Sodium chromate,  $\text{Na}_2\text{CrO}_4$ , is prepared from chromite,  $\text{FeCr}_2\text{O}_4(\text{s})$ , the principal chromium ore, by strongly heating it with sodium carbonate in air. Chromite is an iron(II) chromium(III) oxide, and both iron and chromium are oxidized in this reaction.

Sodium chromate is soluble and can be leached from the mixture with water.

Sodium chromate can be easily converted to sodium dichromate by treating it with an acid. When the yellow solution of a chromate salt is acidified, it turns orange from the formation of dichromate ion,  $\text{Cr}_2\text{O}_7^{2-}(\text{aq})$  (Figure 22.5).

The chromate and dichromate ions are in equilibrium, which is sensitive to pH changes; lower pH favors dichromate ion. (Increasing the  $\text{H}^+$  concentration pushes the equilibrium to the right, according to Le Châtelier's principle.)

The dichromate ion is a strong oxidizing agent in acid solution.

The color of the chromium(III) species depends on anions in solution that can form complexes with  $\text{Cr}^{3+}$ . Frequently the ion is green, so there is a definite color change from orange to green during the reaction.

Chromium(VI) oxide (also called chromium trioxide,  $\text{CrO}_3$ ) is a red, crystalline compound. It precipitates when concentrated sulfuric acid is added to concentrated solutions of a dichromate salt. ▶

Chromium trioxide is an acidic oxide, and its aqueous solutions are referred to as chromic acid. Chromic acid is used in chromium plating.

Chromium trioxide is a strong oxidizing agent. Vapors of ethanol,  $\text{C}_2\text{H}_5\text{OH}$ , spontaneously ignite in the presence of the solid oxide.

**Figure 22.5** ◀

**Chromate–dichromate equilibrium**

The beaker on the left contains  $\text{CrO}_4^{2-}$  (yellow). When the experimenter adds sulfuric acid to a similar solution in the beaker on the right,  $\text{CrO}_4^{2-}$  is converted to  $\text{Cr}_2\text{O}_7^{2-}$  (orange).

Pure chromium metal is prepared by the exothermic reaction of chromium(III) oxide, obtained from chromite ore, with aluminum (the *Goldschmidt process*). Once the reaction mixture is ignited, the large heat of reaction produces molten chromium.

One of the chief uses of chromium is in steel making. For this purpose, chromium is usually prepared directly as an alloy of iron and chromium, called ferrochromium, by reducing chromite ore with carbon in an electric furnace.

## Copper

Copper and the other Group 1B elements, silver and gold, can be found in nature as the free metals. This is a reflection of the stability of their 0 oxidation states. For example, copper is not attacked by most acids.

Copper metal does react with hot, concentrated sulfuric acid and with nitric acid. In these cases, the anion of the acid acts as the oxidizing agent (rather than  $\text{H}^+$ , the usual oxidizing agent in acids). Sulfuric acid is reduced to sulfur dioxide:

Dilute nitric acid is reduced to NO, concentrated nitric acid to  $\text{NO}_2$ :

The copper(II) ion, or cupric ion, given in these equations as  $\text{Cu}^{2+}(aq)$ , is written more precisely as  $[\text{Cu}(\text{H}_2\text{O})_6]^{2+}$ . It has a bright blue color. Hydrated copper(II) salts, such as copper(II) sulfate pentahydrate,  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ , also have a blue color. Four of the water molecules of copper(II) sulfate pentahydrate are associated with  $\text{Cu}^{2+}$ , and the fifth is hydrogen-bonded to the sulfate ion as well as to the water molecules on the copper ion. You can write the formula as  $[\text{Cu}(\text{H}_2\text{O})_4]\text{SO}_4 \cdot \text{H}_2\text{O}$  to better represent its structure. When this salt is heated, it loses its water of hydration in stages. The hydrate  $\text{CuSO}_4 \cdot \text{H}_2\text{O}$  and the anhydrous salt  $\text{CuSO}_4$  are nearly colorless substances; the complexing of water molecules to the copper ion is responsible for the blue color of the pentahydrate.

Although most of the aqueous chemistry of copper involves the +2 oxidation state, there are a number of important compounds of copper(I). When copper is heated in oxygen below  $1000^\circ\text{C}$ , it forms the black copper(II) oxide,  $\text{CuO}$ . But above this temperature, it forms the brick-red copper(I) oxide,  $\text{Cu}_2\text{O}$ . This oxide is found naturally as the mineral cuprite.

The formation of copper(I) oxide by the reduction of copper(II) ion in basic solution forms the basis of a common test for glucose in urine.

When the copper(II) ion is heated in basic solution with a reducing sugar, such as glucose (represented here by the general formula  $\text{RCHO}$ ), the ion is reduced to copper(I) oxide. The blue-green solution of  $\text{Cu}^{2+}$  gives a brick-red precipitate of  $\text{Cu}_2\text{O}$  (Figure 22.6).

The principal commercial use of copper metal is as an electrical conductor. Common ores of copper are native copper (the free metal), copper oxides, and copper sulfides. Most copper is presently obtained by open-pit mining of low-grade rock containing only a small percentage of copper as copper sulfides. The ore is concentrated in copper by flotation. In this process, a slurry of the crushed ore is agitated with air, and the copper sulfides are carried away in the froth. This concentrated ore is then treated in several steps that result in the production of molten

**Figure 22.6** ▲

**Benedict's test for glucose** The experimenter adds glucose solution to a basic solution of copper(II) ion (blue-green solution in left test tube); the solution also contains citrate ion to complex copper(II) ion, so that it will not precipitate as copper(II) hydroxide. When this solution is heated, the glucose reduces copper(II) ion to copper(I) oxide (brick-red precipitate in right test tube).

copper(I) sulfide,  $\text{Cu}_2\text{S}$ . This molten material, called *matte*, is reduced to copper by blowing air through it.

The metal produced is called *blister copper* and is about 99% pure. For electrical use, the copper must be further purified or refined by electrolysis (see Figure 19.24).

## ► Complex Ions and Coordination Compounds

As shown in the previous section, ions of the transition elements exist in aqueous solution as *complex ions*. Iron(II) ion, for example, exists in water as  $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$ . The water molecules in this ion are arranged about the iron atom with their oxygen atoms bonded to the metal by donating electron pairs to it. Replacing the  $\text{H}_2\text{O}$  molecules by six  $\text{CN}^-$  ions gives the  $[\text{Fe}(\text{CN})_6]^{4-}$  ion. Some of the transition elements have biological activity, and their role in human nutrition (Table 22.4) depends in most cases on the formation of *complexes*, or *coordination compounds*, which exhibit the type of bonding that occurs in  $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$  and  $[\text{Fe}(\text{CN})_6]^{4-}$ . In the chapter opening, we saw that hemoglobin, a complex of iron, is vital to the transport of oxygen by the red blood cells.

### 22.3 Formation and Structure of Complexes

A metal atom, particularly a transition-metal atom, often functions in chemical reactions as a Lewis acid, accepting electron pairs from molecules or ions. ► For example,  $\text{Fe}^{2+}$  and  $\text{H}_2\text{O}$  can bond to one another in a Lewis acid–base reaction.

Lewis acid–base reactions are discussed in Section 15.3.

A pair of electrons on the oxygen atom of  $\text{H}_2\text{O}$  forms a coordinate covalent bond to  $\text{Fe}^{2+}$ . In water, the  $\text{Fe}^{2+}$  ion ultimately bonds to six  $\text{H}_2\text{O}$  molecules, forming the  $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$  ion.

The  $\text{Fe}^{2+}$  ion also undergoes a similar Lewis acid–base reaction with cyanide ions. In this case, the  $\text{Fe}^{2+}$  ion bonds to the electron pair on the carbon atom of  $\text{CN}^-$ .

**Table 22.4** Transition Elements Essential to Human Nutrition

Element	Some Biochemical Substances	Function
Chromium	Glucose tolerance factor	Utilization of glucose
Manganese	Isocitrate dehydrogenase	Cell energetics
Iron	Hemoglobin and myoglobin Cytochrome <i>c</i> Catalase	Transport and storage of oxygen Cell energetics Decomposition of hydrogen peroxide
Cobalt	Cobalamin (vitamin $\text{B}_{12}$ )	Development of red blood cells
Copper	Ceruloplasmin Cytochrome oxidase	Synthesis of hemoglobin Cell energetics
Zinc	Carbonic anhydrase Carboxypeptidase A (pancreatic juice) Alcohol dehydrogenase	Elimination of carbon dioxide Protein digestion  Oxidation of ethanol

Although the ion  $[\text{Fe}(\text{CN})_6]^{4-}$  is a complex of  $\text{Fe}^{2+}$  and  $\text{CN}^-$  ions, a solution of  $[\text{Fe}(\text{CN})_6]^{4-}$  contains negligible concentration of  $\text{CN}^-$ . Therefore, a substance such as  $\text{K}_4[\text{Fe}(\text{CN})_6]$  is relatively nontoxic, even though the free cyanide ion is a potent poison.

Finally, a very stable ion,  $[\text{Fe}(\text{CN})_6]^{4-}$ , is obtained, which consists of one  $\text{Fe}^{2+}$  bonded to six cyanide ions. ◀ Note that the charge on the  $[\text{Fe}(\text{CN})_6]^{4-}$  ion equals the sum of the charges on the ions from which it is formed:  $+2 + 6(-1) = -4$ .

In some cases, a neutral species is produced from a metal ion and anions. Cisplatin, the anticancer drug discussed in the opening of Chapter 1, has the structure

It consists of  $\text{Pt}^{2+}$  with two  $\text{NH}_3$  molecules (neutral) and two  $\text{Cl}^-$  ions, giving a neutral species. Iron pentacarbonyl,  $[\text{Fe}(\text{CO})_5]$ , is an example of a neutral species formed from a neutral iron atom and CO molecules.

### Basic Definitions

A **complex ion** is a metal ion with Lewis bases attached to it through coordinate covalent bonds. A **complex** (or **coordination compound**) is a compound consisting either of complex ions and other ions of opposite charge (for example, the compound  $\text{K}_4[\text{Fe}(\text{CN})_6]$  of the complex ion  $[\text{Fe}(\text{CN})_6]^{4-}$  and four  $\text{K}^+$  ions) or of a neutral complex species (such as cisplatin).

**Ligands** are the Lewis bases attached to the metal atom in a complex. They are electron-pair donors, so ligands may be neutral molecules (such as  $\text{H}_2\text{O}$  or  $\text{NH}_3$ ) or anions (such as  $\text{CN}^-$  or  $\text{Cl}^-$ ) that have at least one atom with a lone pair of electrons. Cations only rarely function as ligands. You might expect this, because an electron pair on a cation is held securely by the positive charge, so it would not be involved in coordinate bonding. ◀

The **coordination number** of a metal atom in a complex is the total number of bonds the metal atom forms with ligands. In  $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$ , the iron atom bonds to each oxygen atom in the six water molecules. Therefore, the coordination number of iron in this ion is 6, by far the most common coordination number. Coordination number 4 is also well known, and many examples of number 5 have been discovered.

Table 22.5 gives some examples of complexes for the coordination numbers 2 to 8. The coordination number for an atom depends on several factors, but size of the metal atom is important. For example, coordination numbers 7 and 8 are seen primarily in fifth- and sixth-period elements, whose atoms are relatively large. ◀

### Polydentate Ligands

The ligands we have discussed so far bond to the metal atom through one atom of the ligand. For instance, ammonia bonds through the nitrogen atom. This type of bonding indicates a **monodentate ligand** (meaning “one-toothed” ligand)—that is, a ligand that bonds to a metal atom through one atom of the ligand. A **bidentate ligand** (“two-toothed” ligand) is a ligand that bonds to a metal atom through two atoms of the ligand. Ethylenediamine is an example.

A cation in which the positive charge is far removed from an electron pair that could be donated can function as a ligand. An example is the pyrazinium ion:

Very high coordination numbers (9 to 12) are known for some complex ions of the lanthanide elements.

**Table 22.5** Examples of Complexes of Various Coordination Numbers

Complex	Coordination Number
$[\text{Ag}(\text{NH}_3)_2]^+$	2
$[\text{HgI}_3]^-$	3
$[\text{PtCl}_4]^{2-}$ , $[\text{Ni}(\text{CO})_4]$	4
$[\text{Fe}(\text{CO})_5]$ , $[\text{Co}(\text{CN})_5]^{3-}$	5
$[\text{Co}(\text{NH}_3)_6]^{3+}$ , $[\text{W}(\text{CO})_6]$	6
$[\text{Mo}(\text{CN})_7]^{3-}$	7
$[\text{W}(\text{CN})_8]^{4-}$	8

Figure 22.7 ▲

Structure of tris(ethylenediamine) cobalt(III) ion,  $[\text{Co}(\text{en})_3]^{3+}$

Nitrogen atoms at the ends of the molecule have lone pairs of electrons that can form coordinate covalent bonds. In forming a complex, the ethylenediamine molecule bends around so that both nitrogen atoms coordinate to the metal atom, M.

Because ethylenediamine is a common bidentate ligand, it is frequently abbreviated in formulas as “en.” Figure 22.7 shows the structure of the stable ion  $[\text{Co}(\text{en})_3]^{3+}$ . The oxalate ion,  $\text{C}_2\text{O}_4^{2-}$ , is another common bidentate ligand.

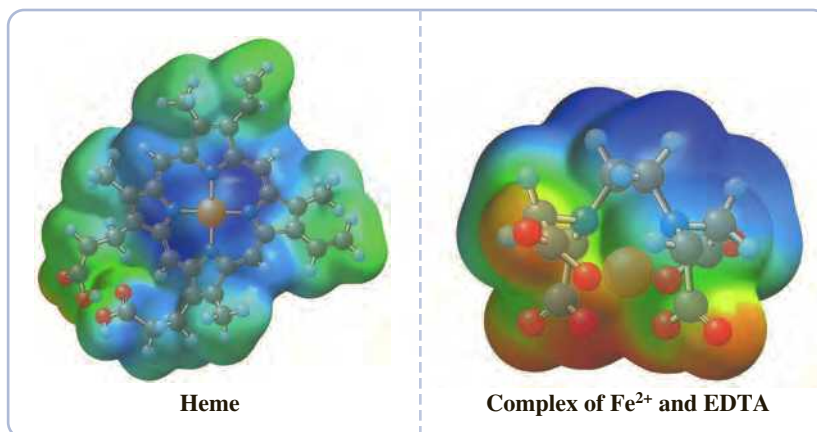

The hemoglobin molecule in red blood cells is an example of a complex with a *quadridentate ligand*—one that bonds to the metal atom through four ligand atoms. Hemoglobin consists of the protein *globin* chemically bonded to *heme*, whose structure is shown in Figure 22.8 (*left*). Heme is a planar molecule consisting of iron(II) to which a quadridentate ligand is bonded through its four nitrogen atoms.

Figure 22.8 ▶

**Complexes with ligands that bond with more than one atom to the metal atom (polydentate ligands)**

*Left:* Structure of heme. *Right:* Complex of  $\text{Fe}^{2+}$  and ethylenediaminetetraacetate ion (EDTA). Note how the EDTA ion envelops the metal ion.

Ethylenediaminetetraacetate ion (EDTA) is a ligand that bonds through six of its atoms.

It can completely envelop a metal atom, simultaneously occupying all six positions in an octahedral geometry (Figure 22.8, right).

A **polydentate ligand** (“having many teeth”) is a ligand that can bond with two or more atoms to a metal atom. A complex formed by polydentate ligands is frequently quite stable and is called a **chelate** (pronounced “key-late”). ◀ Because of the stability of chelates, polydentate ligands (also called *chelating agents*) are often used to remove metal ions from a chemical system. EDTA, for example, is added to certain canned foods to remove transition-metal ions that can catalyze the deterioration of the food. The same chelating agent has been used to treat lead poisoning because it binds  $\text{Pb}^{2+}$  ions as the chelate, forming a substance that can then be excreted by the kidneys.

### Discovery of Complexes; Formula of a Complex

In 1798, B. M. Tassaert found that a solution of cobalt(II) chloride in aqueous ammonia exposed to air (an oxidizing agent) deposits orange-yellow crystals. He assigned the formula  $\text{CoCl}_3 \cdot 6\text{NH}_3$  to these crystals. Later, a similar compound of platinum was assigned the formula  $\text{PtCl}_4 \cdot 6\text{NH}_3$ . Because these formulas suggested that the substances were somehow composed of two stable compounds—platinum(IV) chloride and ammonia in the latter case—they were called complex compounds, or simply complexes.

The basic explanation for the structure of these complexes was given by the Swiss chemist Alfred Werner in 1893. According to Werner, a metal atom exhibits two kinds of valences, a primary valence and a secondary valence. The primary valence is what we now call the oxidation number of the metal. The secondary valence corresponds to what we now call the coordination number, which is often 6. In Werner’s view, the substance previously represented by the formula  $\text{PtCl}_4 \cdot 6\text{NH}_3$  is composed of the ion  $[\text{Pt}(\text{NH}_3)_6]^{4+}$ , with six ammonia molecules directly attached to the platinum atom. The charge of this ion is balanced by four  $\text{Cl}^-$  ions, giving a neutral compound with the structural formula  $[\text{Pt}(\text{NH}_3)_6]\text{Cl}_4$ .

Table 22.6 lists a series of platinum(IV) complexes studied by Werner and both the old and Werner’s modern formulas. (Note that square brackets are used

The term *chelate* is derived from the Greek *chele* for “claw,” because a polydentate ligand appears to attach itself to the metal atom like crab claws to some object.

**Table 22.6** Some Platinum(IV) Complexes Studied by Werner

Old Formula	Modern Formula	Number of Ions	Number of Free Cl <sup>-</sup> Ions
PtCl <sub>4</sub> ·6NH <sub>3</sub>	[Pt(NH <sub>3</sub> ) <sub>6</sub> ]Cl <sub>4</sub>	5	4
PtCl <sub>4</sub> ·4NH <sub>3</sub>	[Pt(NH <sub>3</sub> ) <sub>4</sub> Cl <sub>2</sub> ]Cl <sub>2</sub>	3	2
PtCl <sub>4</sub> ·3NH <sub>3</sub>	[Pt(NH <sub>3</sub> ) <sub>3</sub> Cl <sub>3</sub> ]Cl	2	1
PtCl <sub>4</sub> ·2NH <sub>3</sub>	[Pt(NH <sub>3</sub> ) <sub>2</sub> Cl <sub>4</sub> ]	0	0

in modern formulas to group the metal and its associated ligands.) According to Werner's theory, these complexes should dissolve to give different numbers of ions per formula unit. For example, [Pt(NH<sub>3</sub>)<sub>4</sub>Cl<sub>2</sub>]Cl<sub>2</sub> dissolves to give three ions: [Pt(NH<sub>3</sub>)<sub>4</sub>Cl<sub>2</sub>]<sup>2+</sup> and two Cl<sup>-</sup> ions. Werner was able to show that the electrical conductances of solutions of these complexes were equal to what was expected for the number of ions predicted by his formulas. He also demonstrated that the chloride ions in the platinum complexes were of two kinds: those that could be precipitated from solution as AgCl using silver nitrate and those that could not. He explained that the chloride ions within the platinum complex ion are securely attached to the metal atom and that only those outside the complex ion can be precipitated with silver nitrate. The number of free Cl<sup>-</sup> ions (those not attached to platinum) determined this way agreed exactly with his formulas. Over a period of 20 years, Werner carried out many experiments on complexes, the results of all of them in basic agreement with his theory. He received the Nobel Prize for his work in 1913.

### CONCEPT CHECK 22.1

Another complex studied by Werner had a composition corresponding to the formula PtCl<sub>4</sub>·2KCl. From electrical-conductance measurements, he determined that each formula unit contained three ions. He also found that silver nitrate did not give a precipitate of AgCl with this complex. Write a formula for this complex that agrees with this information.

## 22.4 Naming Coordination Compounds

Thousands of coordination compounds are now known. A systematic method of naming such compounds, or *nomenclature*, needs to provide basic information about the structure of a coordination compound: What is the metal in the complex? Does the metal atom occur in the cation or the anion? What is the oxidation state of the metal? What are the ligands? You can answer these questions by following the rules of nomenclature agreed upon by the International Union of Pure and Applied Chemistry (IUPAC). These rules are essentially an extension of those originally given by Werner.

1. In naming a salt, the name of the cation precedes the name of the anion. (This is a familiar rule.)

K<sub>4</sub>[Fe(CN)<sub>6</sub>] is named potassium hexacyanoferrate(II)  
cation                      anion

[Co(NH<sub>3</sub>)<sub>6</sub>]Cl<sub>3</sub> is named hexaamminecobalt(III) chloride  
cation                      anion

## Salad Dressing and Chelate Stability

The list of ingredients for a particular mayonnaise reads: vegetable oil, eggs, vinegar, and calcium disodium EDTA (ethylenediaminetetraacetate). EDTA? Yes, commercial mayonnaise and salad dressings use EDTA to remove traces of metal ions. Metal ions can catalyze undesirable reactions or else provide nutrient for bacteria, resulting in off-flavors and spoilage of the product. EDTA is a polydentate ligand that forms particularly stable chelates with many metal ions, effectively removing those ions from the product. Many commercial products contain chelating agents such as EDTA (Figure 22.9).

What accounts for the special stability of chelates? Their stability stems from the additional entropy obtained when they are formed. This leads to a large negative  $\Delta G^\circ$ , which is equivalent to a large equilibrium constant for the formation of the chelate. To understand how this happens, consider the formation of the chelate  $[\text{Co}(\text{en})_3]^{3+}$  from the complex ion  $[\text{Co}(\text{NH}_3)_6]^{3+}$ , with monodentate ligands  $\text{NH}_3$ .

Each en molecule replaces two  $\text{NH}_3$  molecules. Therefore, the number of particles in the reaction mixture is increased when the reaction goes to the right. In most cases, an increase in number of particles increases the possibilities for

randomness or disorder. Therefore, when the reaction goes to the right, there is an increase in entropy; that is,  $\Delta S^\circ$  is positive.

At the same time, the reaction involves very little change of internal energy ( $\Delta U^\circ$ ) or enthalpy ( $\Delta H^\circ = \Delta U^\circ + P\Delta V$ ), because the bonds are similar; all consist of a nitrogen atom coordinated to a cobalt atom. Six nitrogen-metal bonds in  $\text{Co}(\text{NH}_3)_6^{3+}$  are broken, and six new nitrogen-metal bonds of about the same energy are formed in  $\text{Co}(\text{en})_3^{3+}$ . Therefore,  $\Delta H^\circ \approx 0$ .

The spontaneity of a reaction depends on  $\Delta G^\circ$ , which equals  $\Delta H^\circ - T\Delta S^\circ$ . But because  $\Delta H^\circ \approx 0$ ,

$$\begin{aligned}\Delta G^\circ &= \Delta H^\circ - T\Delta S^\circ \\ &= -T\Delta S^\circ\end{aligned}$$

The entropy change is positive, so  $\Delta G^\circ$  is negative, and the reaction is spontaneous from left to right.

The fact that the equilibrium for the reaction favors the chelate  $[\text{Co}(\text{en})_3]^{3+}$  means that the chelate has thermodynamic stability. A similar argument could be made for any equilibrium involving the replacement of monodentate ligands by polydentate ligands. Reaction tends to favor the chelate.

**EDTA** *Left:* Mayonnaise and salad dressings contain EDTA to reduce the concentrations of free metal ions. Some plant fertilizers contain EDTA chelates of copper and other metals, providing the metal in a soluble form that plants can utilize. *Right:* An electrostatic potential map of disodium EDTA.

■ See Problems 22.73 and 22.74.

2. The name of the complex—whether anion, cation, or neutral species—consists of two parts written together as one word. Ligands are named first, and the metal atom is named second.

3. The complete ligand name consists of a Greek prefix denoting the number of ligands, followed by the specific name of the ligand. When there are two or more ligands, the ligands are written in alphabetical order (disregarding Greek prefixes).
- a. Anionic ligands end in *-o*. Some examples:

<i>Anion Name</i>	<i>Ligand Name</i>
Bromide, $\text{Br}^-$	Bromo
Carbonate, $\text{CO}_3^{2-}$	Carbonato
Chloride, $\text{Cl}^-$	Chloro
Cyanide, $\text{CN}^-$	Cyano
Fluoride, $\text{F}^-$	Fluoro
Hydroxide, $\text{OH}^-$	Hydroxo
Oxalate, $\text{C}_2\text{O}_4^{2-}$	Oxalato
Oxide, $\text{O}^{2-}$	Oxo
Sulfate, $\text{SO}_4^{2-}$	Sulfato

- b. Neutral ligands are usually given the name of the molecule. There are, however, several important exceptions:

<i>Molecule</i>	<i>Ligand Name</i>
Ammonia, $\text{NH}_3$	Ammine
Carbon monoxide, CO	Carbonyl
Water, $\text{H}_2\text{O}$	Aqua

- c. The prefixes used to denote the number of ligands are *mono-* (1, usually omitted); *di-* (2); *tri-* (3); *tetra-* (4); *penta-* (5); *hexa-* (6); and so forth. To see how the ligand name is formed, consider the complex ions

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCH 02-200-203

- d. When the name of the ligand also has a number prefix, the number of ligands is denoted with *bis* (2), *tris* (3), *tetrakis* (4), and so forth. The name of the ligand follows in parentheses. For example, the complex  $[\text{Co}(\text{en})_3]\text{Cl}_3$  is named as follows:

4. The complete metal name consists of the name of the metal, followed by *-ate* if the complex is an anion, followed by the oxidation number of the metal as a Roman

numeral in parentheses. (An oxidation state of zero is indicated by 0 in parentheses.) When there is a Latin name for the metal, it is usually used to name the anion.

English Name	Latin Name	Anion Name
Copper	Cuprum	Cuprate
Gold	Aurum	Aurate
Iron	Ferrum	Ferrate
Lead	Plumbum	Plumbate
Silver	Argentum	Argentate
Tin	Stannum	Stannate

Examples are

### Example 22.1 Writing the IUPAC Name Given the Structural Formula of a Coordination Compound

#### Gaining Mastery Toolbox

##### Critical Concept 22.1

There are naming rules that apply to coordination compounds. The correct name of a coordination compound conveys important information about the compound, including the name of the metal, the metal's oxidation state, and the name and number of ligands attached to the metal.

##### Solution Essentials:

- Rules for naming coordination compounds
- Ligand
- Coordination compound (complex)
- Complex ion
- Oxidation state

Give the IUPAC name of each of the following coordination compounds:

- a.  $[\text{Pt}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}_2$ ;    b.  $[\text{Pt}(\text{NH}_3)_2\text{Cl}_2]$ ;    c.  $\text{K}_2[\text{PtCl}_6]$ .

**Problem Strategy** Using the naming rules from this section, determine the name of the coordination compounds.

**Solution** a. The cation is listed first in the formula.

There are two  $\text{Cl}^-$  anions, so the charge on the cation is +2:  $[\text{Pt}(\text{NH}_3)_4\text{Cl}_2]^{2+}$ . The oxidation number of platinum plus the sum of the charges on the ligands (-2) equals the cation charge +2. Therefore, the oxidation number of Pt is +4. Hence, the name of the compound is **tetraamminedichloroplatinum(IV) chloride**. Note that the ligands are listed in alphabetical order (that is, ammine before chloro).

b. This is a neutral complex species. The oxidation number of platinum must balance that of the two chloride ions. The name of the compound is **diamminedichloroplatinum(II)**.

c. The complex anion is  $[\text{PtCl}_6]^{2-}$ . The oxidation number of platinum is 4, and the name of the compound is **potassium hexachloroplatinate(IV)**.

**Answer Check** As a final check to problems of this type, take the name that you have come up with for an answer and see if it leads you to writing the correct formula.

**Exercise 22.1** Give the IUPAC names of... a.  $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2$ ;  
b.  $\text{K}_2[\text{Co}(\text{H}_2\text{O})(\text{CN})_5]$ ;    c.  $[\text{Fe}(\text{H}_2\text{O})_5(\text{OH})]^{2+}$ .

See Problems  
22.47, 22.48,  
22.49, and 22.50.

### Example 22.2 Writing the Structural Formula Given the IUPAC Name of a Coordination Compound

#### Gaining Mastery Toolbox

##### Critical Concept 22.2

The name of a coordination compound provides information about the structure of the compound as well as the oxidation state of the metal. In order to write the structural formula of a

Write the structural formula corresponding to each of the following IUPAC names:

- a. hexaaquairon(II) chloride;    b. potassium tetrafluoroargentate(III);  
c. pentachlorotitanate(II) ion.

**Problem Strategy** Examine the complex ion and coordination compound names and work “backward” to find the chemical formula using information from this section.

(continued)

**Example 22.2** (continued)

coordination compound, it is critical to know how to apply the naming rules for coordination compounds.

**Solution Essentials:**

- Rules for naming coordination compounds
- Ligand
- Coordination compound (complex)
- Complex ion
- Oxidation state
- Structural formula

- Solution** a. The complex cation hexaaquairon(II) is  $\text{Fe}^{2+}$  with six  $\text{H}_2\text{O}$  ligands:  $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$ . The formula of the compound is  $[\text{Fe}(\text{H}_2\text{O})_6]\text{Cl}_2$ . (Remember to enclose the formula of the complex ion in square brackets.)
- b. The compound contains the complex anion tetrafluoroargentate(III)—that is,  $\text{Ag}^{3+}$  with four  $\text{F}^-$  ligands. The formula of the ion is  $[\text{AgF}_4]^-$ . Hence, the formula of the compound is  $\text{K}[\text{AgF}_4]$ .
- c. The ion contains  $\text{Ti}^{2+}$  and five  $\text{Cl}^-$  ligands. The charge on the ion is  $+2 + 5(-1) = -3$ . The formula of the complex ion is  $[\text{TiCl}_5]^{3-}$ .

**Answer Check** As a check, once you have written the structural formula, try naming the compound to see if you come up with the IUPAC name.

**Exercise 22.2** Write structural formulas for each of the following:

- a. potassium hexacyanoferrate(II), b. tetraamminedichlorocobalt(III) chloride, c. tetrachloroplatinate(II) ion.

See Problems 22.51 and 22.52.

## 22.5 Structure and Isomerism in Coordination Compounds

Although we described the formation of a complex as a Lewis acid–base reaction (Section 22.3), we did not go into any details of structure. We did not look at the geometry of complex ions or inquire about the precise nature of the bonding. Three properties of complexes have proved pivotal in determining these details.

1. **Isomerism** Isomers are compounds with the same molecular formula (or the same simplest formula, in the case of ionic compounds) but with different arrangements of atoms. Because their atoms are differently arranged, isomers have different properties. There are many possibilities for isomerism in coordination compounds. The study of isomerism can lead to information about atomic arrangement in coordination compounds. Werner's research on the isomerism of coordination compounds finally convinced others that his views were essentially correct.
2. **Paramagnetism** Paramagnetic substances are attracted to a strong magnetic field. Paramagnetism is due to unpaired electrons in a substance. (*Ferromagnetism* in solid iron is also due to unpaired electrons, but in this case the magnetism of many iron atoms is aligned, giving a magnetic effect perhaps a million times stronger than that seen in paramagnetic substances.) Many complex compounds are paramagnetic. The magnitude of this paramagnetism can be measured with a *Gouy balance*, in which the force of magnetic attraction is balanced with weights (Figure 22.10). Because paramagnetism is related to the electron configuration of the complex, these measurements can give information about the bonding and oxidation state.
3. **Color** A substance is colored because it absorbs light in the visible region of the spectrum. The absorption of visible light is due to a transition between electronic energy levels in the range of 1.5 to 3 eV. As you have seen, many coordination compounds are highly colored. The color is related to the electronic structure of the compounds. ▶

In this section, we will investigate the relationship between structure and isomerism. In the following sections, we will look into explanations of the paramagnetism and color of coordination compounds.

There are two major kinds of isomers. **Constitutional isomers** are *isomers that differ in how the atoms are joined together*—that is, in the order in which the atoms are bonded to each other. (For example,  $\text{H}-\text{N}=\text{C}=\text{O}$  and  $\text{N}\equiv\text{C}-\text{O}-\text{H}$  are constitutional isomers because the H atom is bonded to N in one case and to O in the other.) **Stereoisomers**, on the other hand, are *isomers in which the atoms are bonded to each other in the same order but differ in the precise arrangement of the atoms in space*.

**Figure 22.10** ▲ **Gouy balance for measuring the paramagnetism of a substance** If the sample is attracted into the field of the magnet, the left pan of the balance will be subjected to a downward force. This force is balanced by weights added to the right pan.

Recall that the wavelength of light absorbed by a substance is related to the difference between two energy levels in the substance. See Section 7.3.

### Constitutional Isomerism

Coordination compounds provide many special types of constitutional isomers. Here, for example, are two cobalt isomers:

In the first isomer, the sulfate ion is attached to the cobalt atom, and the bromide ion is in the crystal lattice as the anion countering the metal complex cation. In the second isomer, the sulfate ion is in the crystal lattice, with the bromide ion attached to the cobalt atom. ◀

Both the cation and the anion can be metal complex ions, yielding another type of isomer. The following copper–platinum compounds provide an example:

In the first compound, the  $\text{NH}_3$  ligands are associated with a copper atom and the  $\text{Cl}^-$  ligands with a platinum atom. In the second compound, the ligands are transposed.

A more subtle type of constitutional isomer is displayed by the following compounds:

In the first compound, the nitrite ligand,  $\text{NO}_2^-$ , bonds to the cobalt atom through an electron pair on an oxygen atom. This is a red substance that slowly changes to the second compound. In this yellow-brown compound, the nitrite ligand bonds to the cobalt atom through an electron pair on the nitrogen atom. ◀

This type of constitutional isomerism is called *coordination isomerism*.

This type of constitutional isomerism is called *linkage isomerism*.

The isomers of  $[\text{Pt}(\text{NH}_3)_2\text{Cl}_2]$  also differ in their biological properties, as noted in Chapter 1. The orange-yellow compound acts as an anticancer drug; the other isomer does not.

### ✓ CONCEPT CHECK 22.2

A complex has the composition  $\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})\text{BrCl}_2$ . Conductance measurements show that there are three ions per formula unit, and precipitation of  $\text{AgCl}$  with silver nitrate shows that there are two  $\text{Cl}^-$  ions not coordinated to cobalt. What is the structural formula of the compound?

Figure 22.11 ▲

**The tetrahedral complex  $\text{MA}_2\text{B}_2$  has no geometric isomers** The molecule on the top can be rotated to look like the molecule on the bottom. A and B are any two ligands.

### Stereoisomerism

The existence of structural isomers is strong evidence for the view that complexes consist of groups directly bonded to a central metal atom. The existence of stereoisomers not only strengthens this view but also helps explain how the groups are arranged about the central atom.

**Geometric isomers** are *isomers in which the atoms are joined to one another in the same way but differ because some atoms occupy different relative positions in space*. Consider the complex diamminedichloroplatinum(II),  $[\text{Pt}(\text{NH}_3)_2\text{Cl}_2]$ . Two compounds of this composition are known. One is an orange-yellow compound with solubility at  $25^\circ\text{C}$  of 0.252 g per 100 g of water. The other compound is pale yellow and much less soluble (0.037 g per 100 g of water at  $25^\circ\text{C}$ ). ◀ How do you explain the occurrence of these two isomers?

There are two symmetrical geometries of complexes of four ligands: tetrahedral and square planar. Let us write  $\text{MA}_2\text{B}_2$  for a complex with ligands A and B about the metal atom M. As Figure 22.11 shows, a tetrahedral geometry for  $\text{MA}_2\text{B}_2$  allows only one arrangement of ligands. The square planar geometry for  $\text{MA}_2\text{B}_2$ , however, gives two possible arrangements. (The two arrangements for  $[\text{Pt}(\text{NH}_3)_2\text{Cl}_2]$  are shown in Figure 22.12.) One, labeled *cis*, has the two A ligands on one side of the square and the two B ligands on the other side. The other arrangement, labeled *trans*, has A and B ligands across the square from one another. The *cis* and *trans* arrangements of  $\text{MA}_2\text{B}_2$  are examples of geometric isomers.

That there are two isomers of  $[\text{Pt}(\text{NH}_3)_2\text{Cl}_2]$  is evidence for the square planar geometry in this complex. But how do you identify the substances and their

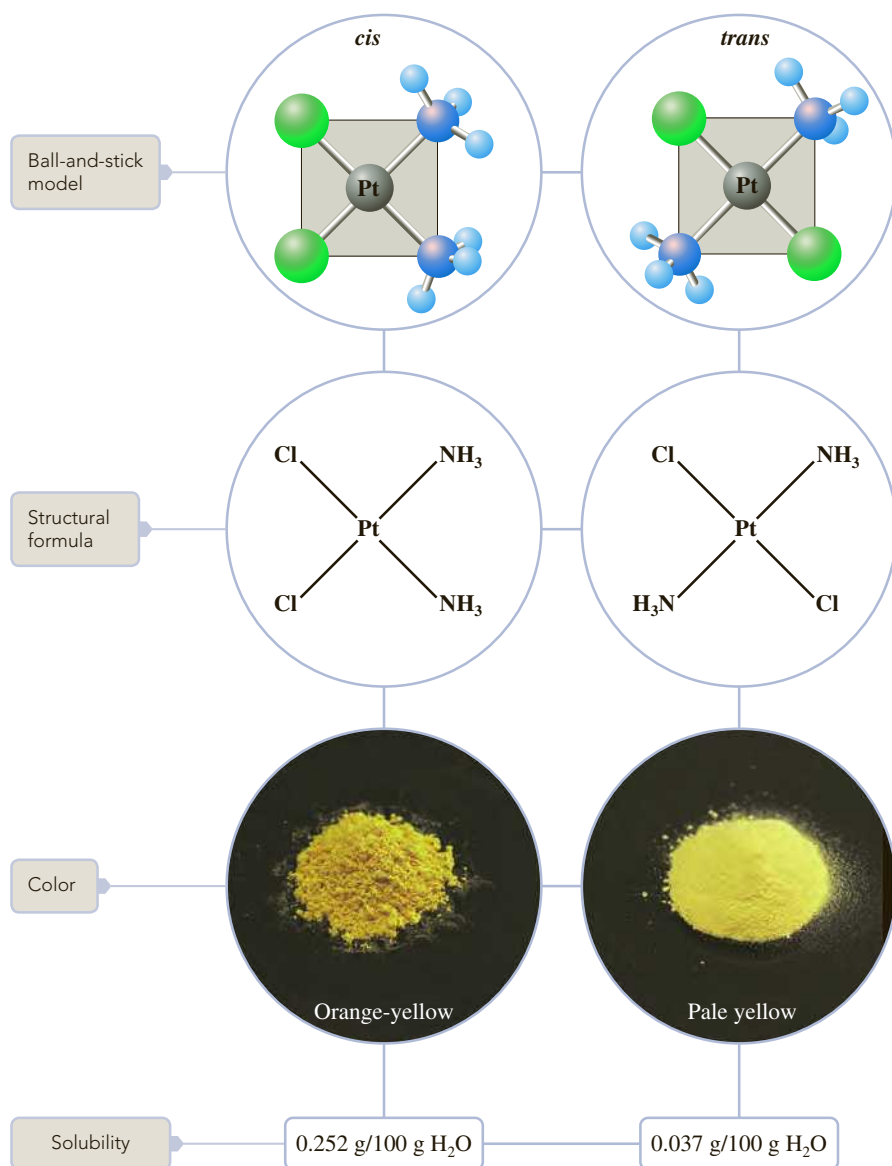

Figure 22.12 ◀

**Geometric isomers of the square planar complex diamminedichloroplatinum(II)**

The existence of two isomers of  $[\text{Pt}(\text{NH}_3)_2\text{Cl}_2]$  is evidence of a square planar geometry. (The tetrahedral geometry would not give isomers.)

properties with the *cis* and *trans* arrangements? You can distinguish between them by predicting their polarity. The *trans* arrangement, being completely symmetrical, is nonpolar. The *cis* arrangement, with electronegative Cl atoms on one side of the platinum atom, is polar. This difference between *cis* and *trans* isomers should be reflected in their solubilities in water, because polar substances are more soluble in water (itself a polar substance) than are nonpolar substances. Thus, you would expect the more soluble isomer to have the *cis* arrangement.

Although the difference in solubility is revealing, the most direct evidence of polarity in a molecule comes from measurements of dipole moment. (The dipole moment is a measure of charge separation in a molecule.) These values show that the less soluble platinum(II) complex has no dipole moment and must be *trans* and that the other isomer does have a dipole moment and must be *cis*. Figure 22.12 shows the two isomers.

Six-coordinate complexes have only one symmetrical geometry: octahedral (Figure 22.13). Geometric isomers are possible for this geometry also. Consider the complex  $\text{MA}_4\text{B}_2$  in which two of the A ligands occupy positions just opposite one another. The other four ligands have a square planar arrangement in which *cis*–*trans* isomers are possible. Tetraamminedichlorocobalt(III) chloride,  $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}$ , is an example of a complex with such geometric isomers. The *cis* compound is purple; the *trans* compound is green. See Figure 22.14.

Figure 22.13 ▶

**Octahedral geometry** (a) All positions in this geometry are equivalent. (b) Octahedral geometry is often represented like this.

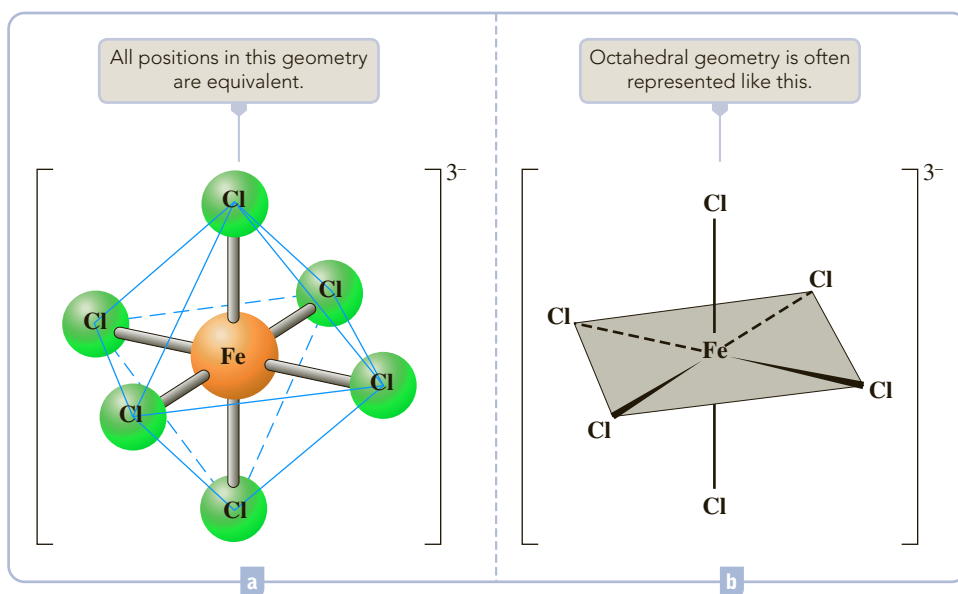

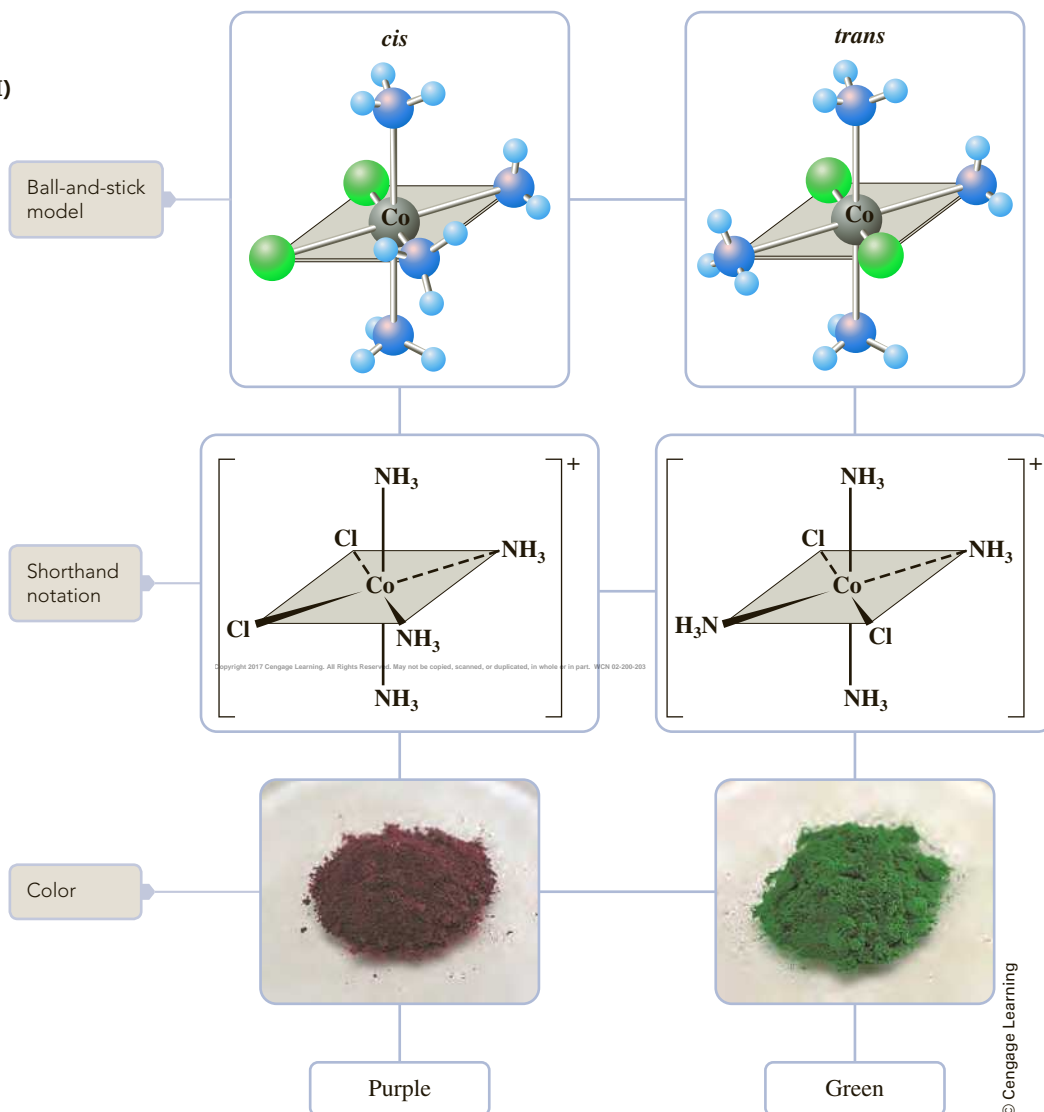

Figure 22.14 ▶

**Geometric isomers of tetraamminedichlorocobalt(III) ion,  $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^+$**  The two isomers have different properties. For example, the *cis* compound is purple; the *trans* compound is green.

**Example 22.3 Deciding Whether Geometric Isomers Are Possible****Gaining Mastery Toolbox****Critical Concept 22.3**

Geometric isomers only occur if the complex has either square planar or octahedral geometry. If the complex has either of these two geometries, determine if pairs of ligands can be placed adjacent to each other, which is *cis*, or across from each other, which is *trans*. Geometric isomers are stereoisomers.

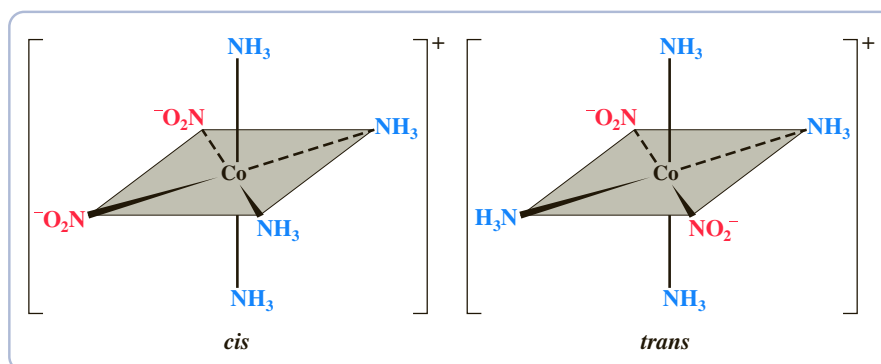

**Solution Essentials:**

- *Cis-trans* isomers
- Geometric isomer
- Stereoisomer
- Complex ion
- Octahedral, tetrahedral, and square planar geometries

Are there any geometric isomers of the complex cation  $[\text{Co}(\text{NH}_3)_4(\text{NO}_2)_2]^+$ ? If so, draw them.

**Problem Strategy** From the formula of the complex ion, determine the geometry. Draw the possible structures, keeping in mind that if the structure is square planar or octahedral, then geometric (*cis-trans*) isomers are possible.

**Solution** Yes, there are geometric isomers. This is easily seen if you first draw two  $\text{NH}_3$  ligands opposite one another in an octahedral geometry. Then the  $\text{NO}_2^-$  ligands can have *cis* or *trans* arrangements on the plane perpendicular to the axis of the first  $\text{NH}_3$  ligands. (See Figure 22.15.)

**Figure 22.15** ▲

***Cis-trans* isomers of  $[\text{Co}(\text{NH}_3)_4(\text{NO}_2)_2]^+$**  Note the arrangements of groups on the gray planes.

**Answer Check** When working a problem such as this that requires thinking in three dimensions, it is very helpful to check your work by building molecular models to represent the structure. For example, for this problem you could build an octahedral model with blue balls representing the  $\text{NH}_3$  ligands and red balls representing the  $\text{NO}_2^-$  ligands.

**Exercise 22.3** Do any of the following stable octahedral complexes have geometric isomers? If so, draw them.

- a.  $[\text{Co}(\text{NH}_3)_5\text{Cl}]^{2+}$     b.  $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2]^{3+}$

See Problems 22.53 and 22.54.

Compounds with both bidentate and monodentate ligands increase the potential for isomerism in octahedral complexes. Figure 22.16 shows the isomers of the dichlorobis(ethylenediamine) cobalt(III) ion,  $[\text{CoCl}_2(\text{en})_2]^+$ . Isomer A is the *trans* isomer (it has a green color). Both B and C are *cis* isomers (both have a violet color). Yet isomers B and C are not identical molecules. They are **enantiomers**, or **optical isomers**; that is, they are *isomers that are nonsuperimposable mirror images of one another*.

To better understand the nature of enantiomers, note that the two *cis* isomers have the same relationship to each other as the relationship of your left hand and right hand. The mirror image of a left hand looks like the right hand, and vice versa (Figure 22.17). But neither the right hand nor the mirror image of the left hand can be turned in any way to look exactly like the left hand; that is, the right and left hands cannot be *superimposed* on one another. (Remember that a left-handed glove does not fit a right hand.) Any physical object *possessing the quality of handedness*—whose mirror image is not identical with itself—is said to be **chiral** (from the Greek *cheir*, meaning “hand”). A glove is chiral. However, a pencil, whose mirror image looks identical to the real pencil, is *achiral*. Isomer A in Figure 22.16 is achiral; its mirror image is identical to itself. Isomer B is chiral; its mirror image, isomer C, is not superimposable on B.

**Figure 22.16** ▲

**Isomers of dichlorobis(ethylenediamine)cobalt(III) ion,  $[\text{CoCl}_2(\text{en})_2]^+$**  Each isomer is shown with its mirror image. N—N represents ethylenediamine. (a) The *trans* isomer and its mirror image are superimposable, so they represent the same molecule. You can see this by rotating the original structure  $90^\circ$  counterclockwise (about the axis perpendicular to the gray plane). (b, c) *Cis* #1 and *cis* #2 are enantiomers (mirror-image, or optical, isomers) of the *cis* form. You cannot rotate one molecule to superimpose it on the other. However, the mirror image of *cis* #1 is identical to *cis* #2. To see this, rotate the mirror image of *cis* #1 by  $180^\circ$  and compare it with *cis* #2.

**Figure 22.17** ▲

**Nonsuperimposable mirror images** The mirror image of the left hand looks like the right hand, but the left hand itself cannot be superimposed on the right hand.

Enantiomers (optical isomers) have identical properties in a symmetrical environment. They have identical melting points and the same solubilities and colors. Enantiomers are usually differentiated by the manner in which they affect *plane-polarized* light. Normally, a light beam consists of electromagnetic waves vibrating in all possible planes about the direction of the beam (Figure 22.18). One of these planes may be selected out by passing a beam of light through a *polarizer* (say through a Polaroid lens). When this plane-polarized light is passed through a solution containing an enantiomer, such as one isomer of *cis*- $[\text{CoCl}_2(\text{en})_2]\text{Cl}$ , the plane of the light wave is twisted. One of the enantiomers twists the plane to the right (as the light comes out toward you); the other isomer twists the plane to the left by the same angle. Because of the ability to rotate the plane of light waves, either as pure substances or in solution, enantiomers are said to be **optically active**. (This is also the origin of the term *optical isomer*.) Figure 22.19 shows a sketch of a *polarimeter*, an instrument that determines the angular change in the plane of a light wave made by an optically active compound.

A compound whose solution rotates the plane of polarized light to the right (when looking toward the source of light) is called **dextrorotatory** and is labeled *d*. A compound whose solution rotates the plane of polarized light to the left (when looking toward the source of light) is called **levorotatory** and is labeled *l*. Thus, the dextrorotatory isomer of *cis*- $[\text{CoCl}_2(\text{en})_2]^+$  is *d-cis*-dichlorobis(ethylenediamine)cobalt(III).

**Figure 22.18** ►

**Polarization of light** Light from the source consists of waves vibrating in various planes along any axis. The polarizer filters out all waves except those vibrating in a particular plane.

Figure 22.19 ◀

**Sketch of a polarimeter** Light from a source (at the left) enters a polarizer prism, which splits the light into polarized components. The component that is polarized vertically enters the sample tube containing a solution of an optically active compound, which rotates the plane of the polarized light by an angle that depends on the compound and its concentration. The experimenter can see the light coming through the analyzer prism only if that prism is rotated by an equivalent angle (degree of rotation).

A chemical reaction normally produces a mixture of equal amounts of optical isomers, called a **racemic mixture**. Because the two isomers rotate the plane of polarized light in equal but opposite directions, a racemic mixture has no net effect on polarized light.

To show that optical isomers exist, a racemic mixture must be separated into its *d* and *l* isomers; that is, the racemic mixture must be *resolved*. One way to resolve a mixture containing *d* and *l* complex ions is to prepare a salt with an optically active ion of opposite charge. For example, the tartaric acid,  $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$ , prepared from the white substance in wine vats is the optically active isomer *d*-tartaric acid. When the racemic mixture of *cis*- $[\text{CoCl}_2(\text{en})_2]\text{Cl}$  is treated with *d*-tartaric acid, the *d*-tartrate salts of *d*- and *l*-*cis*- $[\text{CoCl}_2(\text{en})_2]^+$  may be crystallized. These salts will no longer be optical isomers of one another and will have different solubilities.

### Example 22.4 Deciding Whether Optical Isomers Are Possible

#### Gaining Mastery Toolbox

##### Critical Concept 22.4

Structures that are mirror images and cannot be superimposed are optical isomers. Optical isomerism can only be determined by comparing mirror images.

##### Solution Essentials:

- Optical isomer
- Mirror image
- Geometric isomer
- Stereoisomer
- Complex ion
- Octahedral, tetrahedral, and square planar geometries

Are there optical isomers of the complex  $[\text{Co}(\text{en})_3]\text{Cl}_3$ ? If so, draw them.

**Problem Strategy** Determine the geometry of the complex ion and draw the structures, looking to see whether any structures are nonsuperimposable mirror images.

**Solution** Yes, there are optical isomers, because the complex  $[\text{Co}(\text{en})_3]^{3+}$  has nonsuperimposable mirror images. (See Figure 22.20.)

Figure 22.20 ▲

**Optical isomers of the complex ion  $[\text{Co}(\text{en})_3]^{3+}$**  Note that the isomers are nonsuperimposable mirror images of one another.

(continued)

**Example 22.4** (continued)

**Answer Check** As suggested in the Answer Check to Problem 22.3, you should consider building molecular models to check your work. In this case, be sure to build correctly the linkage that makes up the bidentate ethylenediamine ligand.

**Exercise 22.4** Does either of the following have optical isomers? If so, draw them. a. *trans*-[Co(en)<sub>2</sub>(NO<sub>2</sub>)<sub>2</sub>]<sup>+</sup>  
b. *cis*-[Co(en)<sub>2</sub>(NO<sub>2</sub>)<sub>2</sub>]<sup>+</sup>

See Problems 22.55 and 22.56.

 **CONCEPT CHECK 22.3**

- a** Which of the following molecular models of octahedral complexes are mirror images of the complex X? Keep in mind that you can rotate the models when performing comparisons.
- b** Which complexes are optical isomers of molecule X?
- c** Identify the distinct geometric isomers of complex X. (Note that some of the models may represent the same molecule.)

## 22.6 Valence Bond Theory of Complexes

A complex is formed when electron pairs from ligands are donated to a metal ion. This does not explain how the metal ion can accept electron pairs. Nor does it explain the paramagnetism often observed in complexes. *Valence bond theory* provided the first detailed explanation of the electronic structure of complexes. This explanation is essentially an extension of the view of covalent bonding we described earlier. ◀ According to this view, a covalent bond is formed by the overlap of two orbitals, one from each bonding atom. In the usual covalent bond formation, each orbital originally holds one electron, and after the orbitals overlap, a bond is formed that holds two electrons. In the formation of a coordinate covalent bond in a complex, however, a ligand orbital containing two electrons overlaps an unoccupied orbital on the metal atom. Figure 22.21 diagrams these two bond formations.

See Section 10.3.

Figure 22.21 ▲

Covalent bond formation between atoms X and Y

As an example of complex formation in a transition metal ion, let's look at the formation of the yellow  $[\text{Cr}(\text{NH}_3)_6]^{3+}$  ion. This ion is known from experiment to be paramagnetic. We can think of this ion as formed by complexing  $:\text{NH}_3$  ligands with the free chromium(III) ion. First, we need the configuration of the free ion. The chromium atom configuration is  $[\text{Ar}]3d^54s^1$ . In the formation of a transition-metal ion, the outer  $s$  electrons (here,  $4s^1$ ) are lost first, then the outer  $d$  electrons (here, two of the  $3d^5$  electrons). Therefore,  $\text{Cr}^{3+}$  has the configuration  $[\text{Ar}]3d^3$ . The orbital diagram is

Note that the  $3d^3$  electrons are placed in separate orbitals with their spins in the same direction, following Hund's rule. Two empty  $3d$  orbitals, in addition to orbitals of the  $n = 4$  shell, can be used for bonding to ligands.

To bond electron pairs from six  $:\text{NH}_3$  ligands to  $\text{Cr}^{3+}$ , forming six equivalent bonds, octahedral hybrid orbitals are required. These hybrid orbitals will use two  $d$  orbitals, the  $4s$  orbital, and the three  $4p$  orbitals. The  $d$  orbitals could be either  $3d$  or  $4d$ ; the two available  $3d$  orbitals are used because they have lower energy. We can now write the orbital diagram for the metal atom in the complex:

Electron pairs donated from ligands are shown in color. Note that there are three unpaired electrons in  $3d$  orbitals on the chromium atom, which explains the paramagnetism of the complex ion. The bonding in other complexes can be explained in a similar fashion.

## 22.7 Crystal Field Theory

Although valence bond theory explains the bonding and magnetic properties of complexes, it is limited in two important ways. First, the theory cannot easily explain the color of complexes. Second, the theory is difficult to extend quantitatively. Consequently, another theory—crystal field theory—has emerged as the prevailing view of transition-metal complexes.

**Crystal field theory** is a model of the electronic structure of transition-metal complexes that considers how the energies of the  $d$  orbitals of a metal ion are affected by the electric field of the ligands. According to this theory, the ligands in a transition-metal complex are treated as point charges. So a ligand anion becomes simply a point of negative charge. A neutral molecule, with its electron pair that it

donates to the metal atom, is replaced by a partial negative charge, representing the negative end of the molecular dipole. In the electric field of these negative charges, the five  $d$  orbitals of the metal atom no longer have exactly the same energy. The result, as you will see, explains both the paramagnetism and the color observed in certain complexes.

The simplifications used in crystal field theory are drastic. Treating the ligands as point charges is essentially the same as treating the bonding as ionic. However, it turns out that the theory can be extended to include covalent character in the bonding. This simple extension is usually referred to as *ligand field theory*.

### Effect of an Octahedral Field on the $d$ Orbitals

All five  $d$  orbitals of an isolated metal atom have the same energy. But if the atom is brought into the electric field of several point charges, these  $d$  orbitals may be affected in different ways and therefore may have different energies. To understand how this can happen, you must first see what these  $d$  orbitals look like. You will then be able to picture what happens to them in the crystal field theory of an octahedral complex.

Figure 22.22 shows the shapes of the five  $d$  orbitals. The orbital labeled  $d_{z^2}$  has a dumbbell shape along the  $z$ -axis, with a collar in the  $x$ - $y$  plane surrounding this dumbbell. Remember that this shape represents the volume most likely to be occupied by an electron in this orbital. The other four  $d$  orbitals have “cloverleaf” shapes, differing only in the orientation of the orbitals in space. The “cloverleaf” orbital  $d_{x^2-y^2}$  has its lobes along the  $x$ -axis and the  $y$ -axis. Orbitals  $d_{xy}$ ,  $d_{yz}$ , and  $d_{xz}$  have their lobes directed between the two sets of axes designated in the orbital label. Orbital  $d_{xy}$ , for example, has its lobes lying between the  $x$ - and  $y$ -axes.

**Figure 22.22** ▼

**The five  $d$  orbitals** The  $d_{z^2}$  orbital has a dumbbell shape with a collar; the other orbitals have cloverleaf shapes. In an isolated atom, these orbitals have the same energy. However, in an octahedral complex, the orbitals split into two sets, with the  $d_{z^2}$  and  $d_{x^2-y^2}$  orbitals having higher energy than the other three. Note that the lobes of the  $d_{z^2}$  and  $d_{x^2-y^2}$  orbitals point toward the ligands (represented here by negative charges), whereas the lobes of the other orbitals point between ligands. The repulsion is greater in the case of the  $d_{z^2}$  and  $d_{x^2-y^2}$  orbitals.

A complex ion with six ligands will have the ligands arranged octahedrally about the metal atom to reduce mutual repulsion. Imagine that the ligands are replaced by negative charges. If the ligands are anions, they are replaced by the anion charge. If the ligands are neutral molecules, they are replaced by the partial negative charge from the molecular dipole. The six charges are placed at equal distances from the metal atom, one charge on each of the positive and negative sides of the  $x$ -,  $y$ -, and  $z$ -axes. (See Figure 22.22.)

Fundamentally, the bonding in this model of a complex is due to the attraction of the positive metal ion for the negative charges of the ligands. However, an electron in a  $d$  orbital of the metal atom is repelled by the negative charge of the ligands. This repulsion alters the energy of the  $d$  orbital depending on whether it is directed *toward* or *between* ligands. For example, consider the difference in the repulsive effect of ligands on metal-ion electrons in the  $d_{z^2}$  and  $d_{xy}$  orbitals. Because the  $d_{z^2}$  orbital is directed at the two ligands on the  $z$ -axis (one on the  $-z$  side and the other on the  $+z$  side), an electron in the orbital is rather strongly repelled by them. The energy of the  $d_{z^2}$  orbital becomes greater. Similarly, an electron in the  $d_{xy}$  orbital is repelled by the negative charge of the ligands, but because the orbital is not pointed directly at the ligands, the repulsive effect is smaller. The energy is raised, but less than the energy of the  $d_{z^2}$  orbital is raised.

If you look at the five  $d$  orbitals in an octahedral field (electric field of octahedrally arranged charges), you see that you can divide them into two sets. Orbitals  $d_{z^2}$  and  $d_{x^2-y^2}$  are directed toward ligands, and orbitals  $d_{xy}$ ,  $d_{yz}$ , and  $d_{xz}$  are directed between ligands. The orbitals in the first set ( $d_{z^2}$  and  $d_{x^2-y^2}$ ) have higher energy than those in the second set ( $d_{xy}$ ,  $d_{yz}$ , and  $d_{xz}$ ). Figure 22.23 shows the energy levels of the  $d$  orbitals in an octahedral field. *The difference in energy between the two sets of  $d$  orbitals on a central metal ion that arises from the interaction of the orbitals with the electric field of the ligands is called the crystal field splitting,  $\Delta$ .*

### High-Spin and Low-Spin Complexes

Once you have the energy levels for the  $d$  orbitals in an octahedral complex, you can decide how the  $d$  electrons of the metal ion are distributed in them. Knowing this distribution, you can predict the magnetic characteristics of the complex.

Consider the complex ion  $[\text{Cr}(\text{NH}_3)_6]^{3+}$ . According to crystal field theory, it consists of the  $\text{Cr}^{3+}$  ion surrounded by  $\text{NH}_3$  molecules treated as partial negative charges. The effect of these charges is to split the  $d$  orbitals of  $\text{Cr}^{3+}$  into two sets as shown in Figure 22.23. The question now is how the  $d$  electrons are

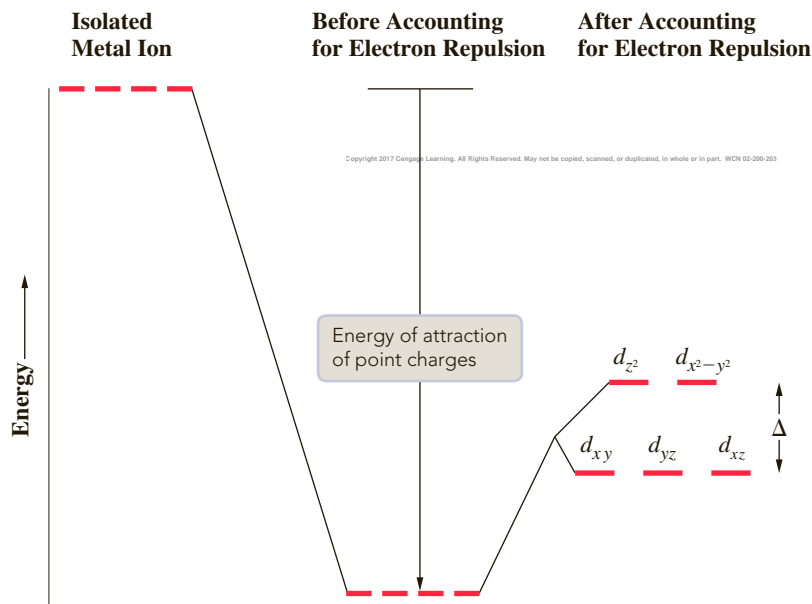

Figure 22.23 ◀

**Energy levels of  $d$  orbitals in an octahedral field** The positive metal ion is attracted to the negative charges (ligands), but electrons in the  $d$  orbitals are repelled by them. Thus, although there is an overall attraction, the  $d$  orbitals no longer have the same energy.

Figure 22.24 ▲

**Occupation of the 3d orbitals in an octahedral complex of Cr<sup>3+</sup>**

The electrons occupy different lower-energy orbitals but have the same spin (Hund's rule).

Figure 22.25 ▲

**Occupation of the 3d orbitals in complexes of Fe<sup>2+</sup>**

(a) Low spin.  
(b) High spin.

distributed among the  $d$  orbitals of the  $\text{Cr}^{3+}$  ion. Because the electron configuration of  $\text{Cr}^{3+}$  is  $[\text{Ar}]3d^3$ , there are three  $d$  electrons to distribute. They are placed in the  $d$  orbitals of lower energy, following Hund's rule (Figure 22.24). You see that the complex ion  $[\text{Cr}(\text{NH}_3)_6]^{3+}$  has three unpaired electrons and is therefore paramagnetic.

If you examine any transition-metal ion that has configuration  $d^4$ ,  $d^5$ ,  $d^6$ , or  $d^7$ , you will find two bonding possibilities, which yield high-spin complexes in one case and low-spin complexes in the other case. A **high-spin complex** is a complex in which there is minimum pairing of electrons in the  $d$  orbitals of the metal atom. A **low-spin complex** is a complex in which there is more pairing of electrons in the  $d$  orbitals of the metal atom than in a corresponding high-spin complex.

Consider the complex ion  $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$ . What are its magnetic characteristics? Remember, you need to look at only the  $d$  electrons of the metal ion,  $\text{Fe}^{2+}$ . The electron configuration of the ion is  $[\text{Ar}]3d^6$ . You distribute six electrons among the  $d$  orbitals of the complex in such a way as to get the lowest total energy. If you place all six electrons into the lower three  $d$  orbitals, you get the distribution shown by the energy-level diagram in Figure 22.25a. All of the electrons are paired, so you would predict that this distribution gives a diamagnetic complex. The  $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$  ion, however, is paramagnetic. Therefore, the distribution given in Figure 22.25a is not correct. What was the mistake?

The mistake was to ignore the **pairing energy,  $P$** , the energy required to put two electrons into the same orbital. When an orbital is already occupied by an electron, it requires energy to put another electron into that orbital because of their mutual repulsion. Suppose that this pairing energy is greater than the crystal field splitting; that is, suppose  $P > \Delta$ . In that case, once the first three electrons have singly occupied the three lower-energy  $d$  orbitals, the fourth electron will go into one of the higher-energy  $d$  orbitals. It will take less energy to do that than to pair up with an electron in one of the lower-energy orbitals. Similarly, the fifth electron will go into the last empty  $d$  orbital. The sixth electron must pair up, so it goes into one of the lower-energy orbitals. Figure 22.25b shows this electron distribution. In this case, there are four unpaired electrons and the complex is paramagnetic.

We see that crystal field theory predicts two possibilities: a *low-spin complex* when  $P < \Delta$  and a *high-spin complex* when  $P > \Delta$ . The value of  $\Delta$ , as we will explain later, can be obtained from the spectrum of a complex, and the value of  $P$  can be calculated theoretically. Even in the absence of these numbers, however, the theory predicts that a paramagnetic octahedral complex of  $\text{Fe}^{2+}$  should have a magnetism equal to that of four unpaired electrons. This is what you find for the  $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$  ion.

You would expect low-spin diamagnetic  $\text{Fe}^{2+}$  complexes to occur for ligands that bond strongly to the metal ion—that is, for those giving large  $\Delta$ . Ligands that might give a low-spin complex are suggested by a look at the spectrochemical series. The **spectrochemical series** is an arrangement of ligands according to the relative magnitudes of the crystal field splittings they induce in the  $d$  orbitals of a metal ion. The following is a short version of the spectrochemical series:

From this series, you see that the  $\text{CN}^-$  ion bonds more strongly than  $\text{H}_2\text{O}$ , which explains why  $[\text{Fe}(\text{CN})_6]^{4-}$  is a low-spin complex ion and  $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$  is a high-spin complex ion. You can also see why carbon monoxide might be expected to be poisonous. You know that  $\text{O}_2$  bonds reversibly to the  $\text{Fe}(\text{II})$  atom of hemoglobin, so the bonding is only moderately strong. According to the spectrochemical series, however, carbon monoxide,  $\text{CO}$ , forms a strong bond. The bonding in this case is irreversible (or practically so). It results in a very stable complex of  $\text{CO}$  and hemoglobin, which cannot function then as a transporter of  $\text{O}_2$ .

**Example 22.5 Describing the Bonding in an Octahedral Complex Ion (Crystal Field Theory)****Gaining Mastery Toolbox****Critical Concept 22.5**

In an octahedral complex, the  $d$ -orbital energy levels of a metal ion are split. This split results in three of the five  $d$  orbitals being lower energy relative to the other two  $d$  orbitals. If the energy difference between the lower- and higher-energy group of orbitals is great enough, electrons will pair up in the lower-energy orbitals prior to entering the higher-energy orbitals.

**Solution Essentials:**

- Pairing energy
- Low-spin complex
- High-spin complex
- Crystal field splitting
- Octahedral field
- Octahedral complex
- $d$  orbitals

Describe the distribution of  $d$  electrons in the complex ion  $[\text{Co}(\text{H}_2\text{O})_6]^{2+}$ , using crystal field theory. The hexaaquacobalt(II) ion is a high-spin complex ion. What would be the distribution of  $d$  electrons in an octahedral cobalt(II) complex ion that is low spin? How many unpaired electrons are there in each ion?

**Problem Strategy** First you need to determine the number of  $d$  electrons in the  $\text{Co}^{2+}$ . Because you are dealing with an octahedral complex, write down the energy levels of the  $d$  orbitals in an octahedral field. Then fill these orbitals with the  $d$  electrons in high-spin (maximum number of unpaired electrons) and low-spin (minimum number of unpaired electrons) configurations, counting the number of unpaired electrons in each case.

**Solution** The electron configuration of  $\text{Co}^{2+}$  is  $[\text{Ar}]3d^7$ . The high-spin and low-spin distributions in the  $d$  orbitals are

$[\text{Co}(\text{H}_2\text{O})_6]^{2+}$ , a high-spin complex, has three unpaired electrons. A low-spin complex would have one unpaired electron.

**Answer Check** Try to avoid the common mistake of assigning an incorrect charge on the metal ion and hence determining the wrong electron configuration.

**Exercise 22.5** Describe the distribution of  $d$  electrons in  $[\text{Ni}(\text{H}_2\text{O})_6]^{2+}$ , using crystal field theory. How many unpaired electrons are there in this ion?

See Problems 22.57 and 22.58.

**Tetrahedral and Square Planar Complexes**

When a metal ion bonds with tetrahedrally arranged ligands, the  $d$  orbitals of the ion split to give two  $d$  orbitals at lower energy and three  $d$  orbitals at higher energy (just the opposite of what is found for an octahedral field). (See Figure 22.26a.) In the field of ligands in a square planar arrangement, the  $d$  orbitals split as shown in Figure 22.26b.

The observed splittings,  $\Delta$ , in a tetrahedral field are approximately one-half the size of those in comparable octahedral complexes. Only high-spin complexes are observed, because the pairing energy is always greater than  $\Delta$ . In the square planar case, only low-spin complexes have been found.

**Figure 22.26** ◀

**Energy splittings of the  $d$  orbitals in a complex with four ligands**

(a) A tetrahedral field. The crystal field splitting,  $\Delta$ , is smaller than in a comparable octahedral complex.  
 (b) A square planar field.

**Example 22.6 Describing the Bonding in a Four-Coordinate Complex Ion (Crystal Field Theory)****Gaining Mastery Toolbox****Critical Concept 22.6**

In tetrahedral and square planar complexes, the  $d$ -orbital energy levels of a metal ion are split. For tetrahedral complexes, this split results in two of the five  $d$  orbitals being lower energy relative to the other three  $d$  orbitals. For square planar complexes, the splitting is more complex. The energy difference of the splitting in a tetrahedral complex is always less than the pairing energy so that all tetrahedral complexes will have the electrons occupy each orbital prior to pairing up. Square planar complexes always have the electrons pair up prior to occupying a higher-energy orbital.

**Solution Essentials:**

- Pairing energy
- Low-spin complex
- High-spin complex
- Crystal field splitting
- Tetrahedral complex
- Square planar complex
- $d$  orbitals

Describe the  $d$ -electron distributions of the complexes  $[\text{Ni}(\text{NH}_3)_4]^{2+}$  and  $[\text{Ni}(\text{CN})_4]^{2-}$ , according to crystal field theory. The tetraamminenickel(II) ion is paramagnetic, and the tetracyanonickelate(II) ion is diamagnetic.

**Problem Strategy** You need to start by recognizing that the complex ions given in the problem are either tetrahedral or square planar. Determine the number of  $d$  electrons in each complex ion. Consulting Figure 22.26, write down the energy splittings of the  $d$  orbitals for tetrahedral and square planar complexes. Then place the electrons in each of your energy splitting diagrams and see which one is consistent with the electron information (paramagnetic or diamagnetic) given in the problem.

**Solution** You expect the tetrahedral field to give high-spin complexes and the square planar field to give low-spin complexes. Therefore, the geometry of the  $[\text{Ni}(\text{NH}_3)_4]^{2+}$  ion, which is paramagnetic, is probably tetrahedral. The distribution of  $d$  electrons in the  $\text{Ni}^{2+}$  ion (configuration  $d^8$ ) is

The geometry of  $[\text{Ni}(\text{CN})_4]^{2-}$ , which is diamagnetic, is probably square planar; the distribution of  $d$  electrons is

**Answer Check** Always check the formula of the complex ion or coordination complex to make certain that you are working with the correct  $d$  orbital energy diagram.

**Exercise 22.6** Describe the distribution of  $d$  electrons in the  $[\text{CoCl}_4]^{2-}$  ion. The ion has a tetrahedral geometry. Assume a high-spin complex.

See Problems 22.59 and 22.60.

**Visible Spectra of Transition-Metal Complexes**

Frequently, substances absorb light only in regions outside the visible spectrum and reflect, or pass on (transmit), all of the visible wavelengths. As a result, these substances appear white or colorless. (White light is a mixture of all visible wavelengths.) However, some substances absorb certain wavelengths in the visible spectrum and transmit the remaining ones; they appear colored. Many transition-metal complexes, as we have noted, are colored substances. The color results from electron jumps, or transitions, between the two closely spaced  $d$  orbital energy levels that come from the crystal field splitting. ◀

The spectrum of a  $d^1$  configuration complex is particularly simple. Hexaaquati-tanium(III) ion,  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ , is an example. Titanium has the configuration  $[\text{Ar}]3d^24s^2$ , and  $\text{Ti}^{3+}$  has the configuration  $[\text{Ar}]3d^1$ . According to crystal field theory, the  $d$  electron occupies one of the lower-energy  $d$  orbitals of the octahedral complex. Figure 22.27 shows the visible spectrum of  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ . It results from a transition, or jump, of the  $d$  electron from a lower-energy  $d$  orbital to a higher-energy  $d$  orbital, as shown in Figure 22.28. Note that the energy change equals the crystal field splitting,  $\Delta$ . Consequently, the wavelength,  $\lambda$ , of light absorbed is related to  $\Delta$ . ◀

$$\Delta = h\nu = \frac{hc}{\lambda} \quad \text{or} \quad \lambda = \frac{hc}{\Delta}$$

The colors of many gemstones are due to transition-metal-ion impurities in the mineral. Ruby has  $\text{Cr}^{3+}$  in alumina,  $\text{Al}_2\text{O}_3$ , and emerald has  $\text{Cr}^{3+}$  in beryl,  $\text{Be}_3\text{Al}_2(\text{SiO}_3)_6$ .

Recall from Section 7.3 that the energy change during a transition equals  $h\nu$ .

Figure 22.27 ◀

**Color and visible spectrum of  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$**  Left: A test tube containing a solution of  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ . Right: Visible spectrum of  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ . Unlike atomic spectra, which show absorption lines, spectra of ions and molecules in solution yield broad bands resulting from changes in nuclear motion that accompany the electronic transitions.

Figure 22.28 ◀

**The electronic transition responsible for the visible absorption in  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$**  An electron undergoes a transition from a lower-energy  $d$  orbital to a higher-energy  $d$  orbital. The energy change equals the crystal field splitting,  $\Delta$ .

When white light, which contains all visible wavelengths (400 nm to 750 nm), falls on a solution containing  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ , blue-green light is absorbed. (The maximum light absorption is observed at 500 nm, which is blue-green light. See Table 22.7.) The other wavelengths of visible light, including red and some blue light, pass through the solution, giving it a red-purple color.

When the ligands in the  $\text{Ti}^{3+}$  complex are changed,  $\Delta$  changes and therefore the color of the complex changes. For example, replacing  $\text{H}_2\text{O}$  ligands by weaker  $\text{F}^-$  ligands should give a smaller crystal field splitting and therefore an absorption at longer wavelengths. The absorption of  $[\text{TiF}_6]^{3-}$  is at 590 nm, in the yellow rather than the blue-green, and the color observed is violet-blue.

Table 22.7 Color Observed for Given Absorption of Light by an Object

Wavelength Absorbed (nm)	Color Absorbed	Approximate Color Observed*
410	Violet	Green-yellow
430	Violet-blue	Yellow
480	Blue	Orange
500	Blue-green	Red
530	Green	Purple
560	Green-yellow	Violet
580	Yellow	Violet-blue
610	Orange	Blue
680	Red	Blue-green
720	Purple-red	Green

\*The exact color depends on the relative intensities of various wavelengths coming from the object and on the response of the eye to those wavelengths.

Life Science

A CHEMIST Looks at . . .

# The Cooperative Release of Oxygen from Oxyhemoglobin

Hemoglobin is an iron-containing substance in red blood cells that is responsible for the transport of  $O_2$  from the lungs to various parts of the body. Myoglobin is a similar substance in muscle tissue, acting as a reservoir for the storage of  $O_2$  and as a transporter of  $O_2$  within muscle cells. The explanation for the different actions of these two substances involves some fascinating transition-metal chemistry.

Myoglobin consists of heme—a complex of Fe(II) bonded to a quadridentate ligand (Figure 22.8)—and globin. Globin, a protein, is attached through a nitrogen atom to one of the octahedral positions of Fe(II). The sixth position is vacant in free myoglobin but is occupied by  $O_2$  in oxy-myoglobin. Hemoglobin is essentially a four-unit structure of myoglobinlike units—that is, a *tetramer* of myoglobin (Figure 22.29).

Myoglobin and hemoglobin exist in equilibrium with the oxygenated forms oxymyoglobin and oxyhemoglobin,

respectively. For example, hemoglobin (Hb) and  $O_2$  are in equilibrium with oxyhemoglobin ( $HbO_2$ ).

Although hemoglobin is a tetramer of myoglobin, it does not function simply as four independent units of myoglobin. For it to function efficiently as a transporter of  $O_2$  from the lungs and then be able to release that  $O_2$  easily to myoglobin, hemoglobin must be less strongly attached to  $O_2$  in the vicinity of a muscle cell than is myoglobin. In hemoglobin, the release of  $O_2$  from one heme group triggers the release of  $O_2$  from another heme group of the same molecule. In other words, there is a *cooperative release* of  $O_2$  from hemoglobin that makes it possible for it to give up its  $O_2$  to myoglobin.

The mechanism postulated for this cooperative release of  $O_2$  depends on a change of iron(II) from a low-spin to a high-spin form, with a corresponding change in radius of the iron atom. In oxyhemoglobin, iron(II) exists in the low-spin form. When  $O_2$  leaves, the iron atom goes to a high-spin form with two electrons in the higher-energy  $d$  orbital. These higher-energy orbitals are somewhat larger than the lower-energy  $d$  orbitals.

**Figure 22.29** ▲

**Hemoglobin** A molecular model of hemoglobin that depicts each of the iron-containing heme groups contained in the four subunits.

When an  $O_2$  molecule leaves a heme group, the radius of the iron atom increases, and the atom pops out of the heme plane by about 70 pm. In hemoglobin, this change triggers the cooperative release of another  $O_2$  molecule. As the iron atom moves, the attached globin group moves with it. This motion of one globin group causes an adjacent globin group in the tetramer to alter its shape, which in turn makes possible the easy release of an  $O_2$  molecule from its heme unit.

■ See Problems 22.75 and 22.76.

From this discussion, you see that the visible spectrum can be related to the crystal field splitting, and values of  $\Delta$  can be obtained by spectroscopic analysis. However, when there is more than one  $d$  electron, several excited states can be formed. Consequently, the spectrum generally consists of several lines, and the analysis is more complicated than for  $Ti^{3+}$ .

**Example 22.7 Predicting the Relative Wavelengths of Absorption of Complex Ions****Gaining Mastery Toolbox****Critical Concept 22.7**

The greater the crystal field splitting in the complex, the higher the energy of light absorbed by the complex. The spectrochemical series can be used to determine the relative amount of ligand field splitting produced by different ligands. Those ligands that bond to the metal most strongly cause the complex to absorb the highest-energy light (shortest wavelength).

**Solution Essentials:**

- Ligand
- Coordination compound (complex)
- Crystal field splitting
- Spectrochemical series
- Energy of light
- Frequency and wavelength of light

When water ligands in  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$  are replaced by  $\text{CN}^-$  ligands to give  $[\text{Ti}(\text{CN})_6]^{3-}$ , the maximum absorption shifts from 500 nm to 450 nm. Is this shift in the expected direction? Explain. What color do you expect to observe for this ion?

**Problem Strategy** We are going to need to consult the spectrochemical series in order to do this problem. Keeping this in mind, those ligands that cause a greater crystal field splitting will absorb higher-energy light.

**Solution** According to the spectrochemical series,  $\text{CN}^-$  is a more strongly bonding ligand than  $\text{H}_2\text{O}$ . Consequently,  $\Delta$  should increase, and the wavelength of the absorption ( $\lambda = hc/\Delta$ ) should decrease. **So the shift of the absorption is in the expected direction.** Because the absorbed light is between blue and violet-blue (see Table 22.7), the observed color is **orange-yellow** (this is the *complementary color* of the color between blue and violet-blue).

**Answer Check** Check to make certain that you have correctly applied the relationship between the wavelength of light and its energy: the longer the wavelength, the lower the energy.

**Exercise 22.7** The  $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$  ion has a pale purple color, and the  $[\text{Fe}(\text{CN})_6]^{3-}$  ion has a ruby-red color. What are the approximate wavelengths of the maximum absorption for each ion? Is the shift of wavelength in the expected direction? Explain.

See Problems  
22.61, 22.62,  
22.63, and 22.64.

**A Checklist for Review****Summary of Facts and Concepts**

The *d-block transition elements* are defined as those elements having a partially filled *d* subshell in any common oxidation state. They have a number of characteristics, including high melting points and a multiplicity of oxidation states. Compounds of transition elements are frequently colored and many are paramagnetic. These properties are due to the participation of *d* orbitals in bonding. We described the chemical properties of two transition elements: Cr and Cu. Chromium metal reacts with acids to give  $\text{Cr}^{2+}$  ion, which is readily oxidized to  $\text{Cr}^{3+}$ . The +3 state is the most common oxidation state; chromium(III) oxide is a green pigment. The +6 oxidation state is represented by chromates and dichromates. The dichromate ion,  $\text{Cr}_2\text{O}_7^{2-}$ , in acid solution is a strong oxidizing agent. Chromium metal is obtained by reduction of the ore chromite,  $\text{FeCr}_2\text{O}_4$ . Copper metal reacts only with acids having strongly oxidizing anions, such as  $\text{HNO}_3$ ; it gives  $\text{Cu}^{2+}$  ion. Copper(I) oxide,  $\text{Cu}_2\text{O}$ , occurs naturally as a copper mineral. This oxide also forms as a brick-red precipitate when copper(II) ion is reduced in basic solution. The reaction is used as a test for glucose.

Transition-metal atoms often function as Lewis acids, reacting with groups called *ligands* by forming coordinate covalent bonds to them. The metal atom with its ligands is a *complex ion* or neutral *complex*. Ligands that bond through more than one atom are called *polydentate*, and the complex formed is called a *chelate*. The IUPAC has agreed

on a nomenclature of complexes that gives basic structural information about the species. The presence of isomers in coordination compounds is evidence for particular geometries. For example,  $[\text{Pt}(\text{NH}_3)_2\text{Cl}_2]$  has two isomers, which is evidence for a square planar geometry having *cis-trans isomers*. Octahedral complexes, often those that have bidentate ligands, may have *optical isomers*—that is, isomers that are mirror images of one another.

*Valence bond theory* gave the earliest theoretical description of the electronic structure of a complex. According to this theory, a complex forms when doubly occupied ligand orbitals overlap unoccupied orbitals of the metal atom.

*Crystal field theory* treats the ligands as electric charge points that affect the energy of the *d* orbitals of the metal ion. In an octahedral complex, two of the *d* orbitals have higher energy than the other three. A high-spin complex forms when the *pairing energy* is greater than the *crystal field splitting*, so that electrons would “prefer” to occupy a higher-energy *d* orbital rather than pair up with an electron in a lower-energy orbital. When the pairing energy is smaller than the crystal field splitting, the *d* orbitals are occupied in the normal fashion, giving a low-spin complex. Color in transition-metal complexes is explained as due to a transition of an electron from the lower-energy to the higher-energy *d* orbitals. The crystal field splitting can be obtained experimentally from the visible spectrum of a complex.

## Questions and Problems

### Self-Assessment and Review Questions

**Key:** These questions test your understanding of the ideas you worked with in the chapter. These problems vary in difficulty and often can be used for the basis of discussion.

**22.1** What characteristics of the transition elements set them apart from the main-group elements?

**22.2** According to the building-up principle, what is the electron configuration of the ground state of the yttrium atom (atomic number 39)?

**22.3** The highest melting point for metals in the fifth period occurs for molybdenum. Explain why this is expected.

**22.4** Iron, cobalt, and nickel are similar in properties and are sometimes studied together as the “iron triad.” For example, each is a fairly active metal that reacts with acids to give hydrogen and the +2 ions. In addition to the +2 ions, the +3 ions of the metals also figure prominently in the chemistries of the elements. Explain why these elements are similar.

**22.5** Palladium and platinum are very similar to one another. Both are unreactive toward most acids. However, nickel, which is in the same column of the periodic table, is an active metal. Explain why this difference exists.

**22.6** Write balanced equations for the reactions of Cr and Cu metals with  $\text{HCl}(aq)$ . If no reaction occurs, write *NR*.

**22.7** Write balanced equations for the reactions of chromium(III) oxide with a strong acid.

**22.8** Describe the structure of copper(II) sulfate pentahydrate. What color change occurs when the salt is heated? What causes the color change?

**22.9** Silver(I) ion in basic solution is reduced by formaldehyde,  $\text{HCHO}$ , to Ag metal. Formaldehyde is oxidized to formate ion,  $\text{HCOO}^-$ . Write the balanced equation for this reaction.

**22.10** What evidence did Werner obtain to show that the platinum complex  $\text{PtCl}_4 \cdot 4\text{NH}_3$  has the structural formula  $[\text{Pt}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}_2$ ?

**22.11** Define the terms *complex ion*, *ligand*, and *coordination number*. Use an example to illustrate the use of these terms.

**22.12** Define the term *bidentate ligand*. Give two examples.

**22.13** Rust spots on clothes can be removed by dissolving the rust in oxalic acid. The oxalate ion forms a stable complex with  $\text{Fe}^{3+}$ . Using an electron-dot formula, indicate how an oxalate ion bonds to the metal ion.

**22.14** What three properties of coordination compounds have been important in determining the details of their structure and bonding?

**22.15** Define each of the following and give an example of each: **a** ionization isomerism, **b** hydrate isomerism, **c** coordination isomerism, **d** linkage isomerism.

**22.16** Define the terms *geometric isomerism* and *optical isomerism* and give an example of each.

**22.17** Explain the difference in behavior of *d* and *l* isomers with respect to polarized light.

**22.18** What is a racemic mixture? Describe one method of resolving a racemic mixture.

**22.19** Describe the formation of a coordinate covalent bond between a metal-ion orbital and a ligand orbital.

**22.20** **a** Describe the steps in the formation of a high-spin octahedral complex of  $\text{Fe}^{2+}$  in valence bond terms. **b** Do the same for a low-spin complex.

**22.21** Explain why *d* orbitals of a transition-metal atom may have different energies in the octahedral field of six negative charges. Describe how each of the *d* orbitals is affected by the octahedral field.

**22.22** **a** Use crystal field theory to describe a high-spin octahedral complex of  $\text{Cr}^{2+}$ . **b** Do the same for a low-spin complex.

**22.23** What is meant by the term *crystal field splitting*? How is it determined experimentally?

**22.24** What is the spectrochemical series? Use the ligands  $\text{CN}^-$ ,  $\text{H}_2\text{O}$ ,  $\text{Cl}^-$ , and  $\text{NH}_3$  to illustrate the term. Then arrange them in order, describing the meaning of this order.

**22.25** What is meant by the term *pairing energy*? How do the relative values of pairing energy and crystal field splitting determine whether a complex is low-spin or high-spin?

**22.26** A complex absorbs blue-green light from a single electron transition. What color is this complex?

**22.27** What is the coordination number of the transition metal in the complex  $[\text{Cr}(\text{en})_2(\text{C}_2\text{O}_4)]\text{ClO}_4$ ?

- a** 2   **b** 3   **c** 4   **d** 5   **e** 6

**22.28** Which of the following is most likely a tetrahedral complex?

- a**  $[\text{Zn}(\text{NH}_3)_2\text{Cl}_2]$    **b**  $[\text{Co}(\text{NH}_3)_3\text{Cl}_3]$   
**c**  $[\text{Co}(\text{NH}_3)_6]^{2+}$    **d**  $[\text{Ni}(\text{H}_2\text{O})_6]\text{SO}_4$   
**e**  $[\text{Co}(\text{en})_2(\text{H}_2\text{O})\text{Cl}]^{2+}$

**22.29** What is the correct name for the coordination compound  $[\text{Cr}(\text{en})_2(\text{CN})_2]\text{Cl}$ ?

- a** chromium(III) (diethylenediamine)biscyano chloride  
**b** dicyanobis(ethylenediamine)chromium(III) chloride  
**c** dicyanobis(ethylenediamine)chromium(III) dichloride  
**d** bis(ethylenediamine)dicyanochromium(III) chloride  
**e** bis(ethylenediamine)dicyanochromium(III) dichloride

**22.30** What is the number of unpaired electrons in the low-spin complex  $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3$

- a** 0   **b** 1   **c** 2   **d** 3   **e** 4

### Conceptual Problems

**Key:** These problems are designed to check your understanding of the concepts associated with some of the main topics presented in each chapter. A strong conceptual understanding of chemistry is the foundation for both applying chemical knowledge and solving chemical problems. These problems vary in level of difficulty and often can be used as a basis for group discussion.

**22.31** A cobalt complex whose composition corresponded to the formula  $\text{Co}(\text{NO}_2)_2\text{Cl} \cdot 4\text{NH}_3$  gave an electrical conductance equivalent to two ions per formula unit. Excess silver nitrate solution immediately precipitates 1 mol  $\text{AgCl}$  per formula unit. Write a structural formula consistent with these results.

## 810b

## The Transition Elements and Coordination Compounds

22.32 For the following coordination compounds, identify the geometric isomer(s) of compound X.

22.33 Describe step by step how the name potassium hexacyanoferrate(II) leads to the structural formula  $K_4[Fe(CN)_6]$ .

22.34 Compounds A and B are known to be stereoisomers of one another. Compound A has a violet color; compound B has a green color. Are they geometric or optical isomers?

22.35 A complex has a composition corresponding to the formula  $CoBr_2Cl \cdot 4NH_3$ . What is the structural formula if conductance measurements show two ions per formula unit? Silver nitrate solution gives an immediate precipitate of  $AgCl$  but no  $AgBr$ . Write the structural formula of an isomer.

22.36 For the complexes shown here, which would have the  $d$  electron distribution shown in the diagram below:  $[MF_6]^{3-}$ ,  $[M(CN)_6]^{3-}$ ,  $[MF_6]^{4-}$ ,  $[M(CN)_6]^{4-}$ ? Note that the neutral metal atom,  $M$ , in each complex is the same and has the ground state electron configuration  $[Ar]4s^23d^6$ .

## Practice Problems

**Key:** These problems are for practice in applying problem-solving skills. They are divided by topic, and some are keyed to exercises (see the ends of the exercises). The problems are arranged in matching pairs; the odd-numbered problem of each pair is listed first, and its answer is given in the back of the book.

## Properties of the Transition Elements

22.37 Find the oxidation numbers of the transition metal in each of the following compounds:

22.38 Find the oxidation numbers of the transition metal in each of the following compounds:

22.39 Write the balanced equation for the reaction of iron(II) ion with nitrate ion in acidic solution. Nitrate ion is reduced to  $NO$ .

22.40 Write the balanced equation for the reaction of sulfurous acid with dichromate ion.

## Structural Formulas and Naming of Complexes

22.41 Give the coordination number of the transition-metal atom in each of the following complexes.

22.42 Give the coordination number of the transition element in each of the following complexes.

22.43 Determine the oxidation number of the transition element in each of the following complexes.

22.44 For each of the following complexes, determine the oxidation state of the transition-metal atom.

22.45 Consider the complex ion  $[CoCl(en)_2(NO_2)]^+$ .

- a What is the oxidation state of the metal atom?  
b Give the formula and name of each ligand in the ion.  
c What is the coordination number of the metal atom?  
d What would be the charge on the complex if all ligands were chloride ions?

22.46 Consider the complex ion  $[Mn(NH_3)_2(H_2O)_3(OH)]^{2+}$ .

- a What is the oxidation state of the metal atom?  
b Give the formula and name of each ligand in the ion.  
c What is the coordination number of the metal atom?  
d What would be the charge on the complex if all ligands were chloride ions?

22.47 Write the IUPAC name for each of the following coordination compounds.

22.48 Name the following complexes, using IUPAC rules.

22.49 Give the IUPAC name for each of the following.

22.50 Give the IUPAC name for each of the following.

**22.51** Write the structural formula for each of the following compounds.

- a potassium hexacyanomanganate(III)
- b sodium tetracyanozincate(II)
- c tetraamminedichlorocobalt(III) nitrate
- d hexaamminechromium(III) tetrachlorocuprate(II)

**22.52** Give the structural formula for each of the following complexes.

- a diaquadicyanocopper(II)
- b potassium hexachloroplatinate(IV)
- c tetraamminenickel(II) perchlorate
- d tetraammineplatinum(II) tetrachlorocuprate(II)

### Isomerism

**22.53** Draw *cis-trans* structures of any of the following square planar or octahedral complexes that exhibit geometric isomerism. Label the drawings *cis* or *trans*.

- a  $[\text{Pd}(\text{NH}_3)_2\text{Cl}_2]$
- b  $[\text{Pd}(\text{NH}_3)_3\text{Cl}]^+$
- c  $[\text{Pd}(\text{NH}_3)_4]^{2+}$
- d  $[\text{Ru}(\text{NH}_3)_4\text{Br}_2]^+$

**22.54** If any of the following octahedral complexes display geometric isomerism, draw the structures and label them *cis* or *trans*.

- a  $[\text{Co}(\text{NO}_2)_4(\text{NH}_3)_2]^-$
- b  $[\text{Co}(\text{NH}_3)_5(\text{NO}_2)]^{2+}$
- c  $[\text{Co}(\text{NH}_3)_6]^{3+}$
- d  $[\text{Cr}(\text{NH}_3)_5\text{Cl}]^{2+}$

**22.55** Determine whether there are optical isomers of any of the following. If so, sketch the isomers.

- a *cis*- $[\text{Co}(\text{NH}_3)_2(\text{en})_2]^{3+}$
- b *trans*- $[\text{IrCl}_2(\text{C}_2\text{O}_4)]^{3-}$

**22.56** Sketch mirror images of each of the following. From these sketches, determine whether optical isomers exist and note this fact on the drawings.

- a  $[\text{Rh}(\text{en})_3]^{3+}$
- b *cis*- $[\text{Cr}(\text{NH}_3)_2(\text{SCN})_4]^-$

### Crystal Field Theory

**22.57** Using crystal field theory, sketch the energy-level diagram for the *d* orbitals in an octahedral field; then fill in the electrons for the metal ion in each of the following complexes. How many unpaired electrons are there in each case?

- a  $[\text{V}(\text{CN})_6]^{3-}$
- b  $[\text{Co}(\text{C}_2\text{O}_4)_3]^{4-}$  (high-spin)
- c  $[\text{Mn}(\text{CN})_6]^{3-}$  (low-spin)

**22.58** Using crystal field theory, sketch the energy-level diagram for the *d* orbitals in an octahedral field; then fill in the electrons for the metal ion in each of the following complexes. How many unpaired electrons are there in each case?

- a  $[\text{ZrCl}_6]^{4-}$
- b  $[\text{OsCl}_6]^{2-}$  (low-spin)
- c  $[\text{MnCl}_6]^{4-}$  (high-spin)

**22.59** Obtain the distribution of *d* electrons in the complex ions listed below, using crystal field theory. Each ion is either tetrahedral or square planar. On the basis of the number of unpaired electrons (given in parentheses), decide the correct geometry.

- a  $[\text{Pt}(\text{NH}_3)_4]^{2+}$  (0)
- b  $[\text{Co}(\text{en})_2]^{2+}$  (1)
- c  $[\text{FeCl}_4]^-$  (5)
- d  $[\text{Co}(\text{NCS})_4]^{2-}$  (3)

**22.60** Obtain the distribution of *d* electrons in the complex ions listed below, using crystal field theory. Each ion is either tetrahedral or square planar. On the basis of the number of unpaired electrons (given in parentheses), decide the correct geometry.

- a  $[\text{Pt}(\text{NH}_3)_2(\text{NO}_2)_2]^{2+}$  (2)
- b  $[\text{MnCl}_4]^{2-}$  (5)
- c  $[\text{NiCl}_4]^{2-}$  (2)
- d  $[\text{AuF}_4]^-$  (0)

### Color

**22.61** The  $[\text{CoF}_6]^{3-}$  ion has a maximum absorption at 700 nm. What color do you expect for this ion?

**22.62** The  $[\text{Co}(\text{en})_3]^{3+}$  ion has a maximum absorption at 470 nm. What color do you expect for this ion?

**22.63** The  $[\text{Co}(\text{NH}_3)_6]^{3+}$  ion has a yellow color, but when one  $\text{NH}_3$  ligand is replaced by  $\text{H}_2\text{O}$  to give  $[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})]^{3+}$ , the color shifts to red. Is this shift in the expected direction? Explain.

**22.64** The  $[\text{Co}(\text{en})_3]^{3+}$  ion has a yellow color, but the  $[\text{CoF}_6]^{3-}$  ion has a blue color. Is the shift from yellow to blue expected when ethylenediamine ligands are replaced by  $\text{F}^-$  ligands? Explain.

**22.65** What is the value of  $\Delta$  (in kJ/mol) when  $\lambda = 454$  nm, corresponding to an electron jump between *d*-orbital levels in a complex with a  $d^1$  configuration?

**22.66** What is the value of  $\Delta$  (in kJ/mol) when  $\lambda = 680$  nm, corresponding to an electron jump between *d*-orbital levels in a complex with a  $d^1$  configuration?

## General Problems

**Key:** These problems provide more practice but are not divided by topic or keyed to exercises. Each section ends with essay questions, each of which is color coded to refer to the *A Chemist Looks at Daily Life* (orange) or *A Chemist Looks at Life Science* (pink) chapter essay on which it is based. Odd-numbered problems and the even-numbered problems that follow are similar; answers to all odd-numbered problems except the essay questions are given in the back of the book.

**22.67** The hexaaquascandium(III) ion,  $[\text{Sc}(\text{H}_2\text{O})_6]^{3+}$ , is colorless. Explain why this might be expected.

**22.68** The tetraaquazinc(II) ion,  $[\text{Zn}(\text{H}_2\text{O})_4]^{2+}$ , is colorless. Explain why this might be expected.

**22.69** There are only two geometric isomers of the tetraamminedichlorocobalt(III) ion,  $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^{3+}$ . How many geometric isomers would be expected for this ion if it had a regular planar hexagonal geometry? Give drawings for

them. Does this rule out a planar hexagonal geometry for  $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^+$ ? Explain.

**22.70** There are only two geometric isomers of the triamminetrichloroplatinum(IV) ion,  $[\text{Pt}(\text{NH}_3)_3\text{Cl}_3]^+$ . How many geometric isomers would be expected for this ion if it had a regular planar hexagonal geometry? Give drawings for them. Does this rule out a planar hexagonal geometry for  $[\text{Pt}(\text{NH}_3)_3\text{Cl}_4]^+$ ? Explain.

**22.71** Find the concentrations of  $\text{Cu}^{2+}(aq)$ ,  $\text{NH}_3(aq)$ , and  $[\text{Cu}(\text{NH}_3)_4]^{2+}(aq)$  at equilibrium when 0.10 mol  $\text{Cu}^{2+}(aq)$  and 0.40 mol  $\text{NH}_3(aq)$  are made up to 1.00 L of solution. The dissociation constant,  $K_d$ , for the complex  $[\text{Cu}(\text{NH}_3)_4]^{2+}$  is  $2.1 \times 10^{-13}$ .

**22.72** Find the concentrations of  $\text{Ag}^+(aq)$ ,  $\text{NH}_3(aq)$ , and  $[\text{Ag}(\text{NH}_3)_2]^+(aq)$  at equilibrium when 0.10 mol  $\text{Ag}^+(aq)$

and 0.10 mol  $\text{NH}_3(aq)$  are made up to 1.00 L of solution. The dissociation constant,  $K_d$ , for the complex  $[\text{Ag}(\text{NH}_3)_2]^+$  is  $5.9 \times 10^{-8}$ .

**22.73** Why is EDTA added to commercial mayonnaise and salad dressings? Explain what is happening.

**22.74** What accounts for the special stability of chelates? Explain this in terms of an example.

**22.75** Describe the functions of hemoglobin and myoglobin in the body. What is similar and what is different about the two functions?

**22.76** Describe the mechanism of the cooperative release of oxygen from oxyhemoglobin.

## Strategy Problems

**Key:** As noted earlier, all of the practice and general problems are matched pairs. This section is a selection of problems that are not in matched-pair format. These challenging problems require that you employ many of the concepts and strategies that were developed in the chapter. In some cases, you will have to integrate several concepts and operational skills in order to solve the problem successfully.

**22.77** Consider the complex ion  $[\text{CoCO}_3(\text{NH}_3)_4]^+$ , where the  $\text{CO}_3^{2-}$  is a bidentate ligand.

- Is this complex ion octahedral or square planar?
- What is the oxidation state of the cobalt?

**22.78** Does the complex ion  $[\text{Co}(\text{en})_2\text{Cl}_2]^+$  have *cis-trans* geometric isomers?

**22.79** Draw each of the following to determine if they have optical isomers.

- $\text{Ir}(\text{en})_3^{3+}$
- $[\text{Ir}(\text{H}_2\text{O})_3\text{Cl}_3]$

**22.80** Is it possible for a square planar complex to have optical isomers?

**22.81** The complex  $[\text{Fe}(\text{en})_2\text{Cl}_2]\text{Cl}$  is low spin.

- What is the geometry of the complex ion?
- What is the oxidation state of the Fe?
- Are there geometric isomers, and is the compound optically active?

**22.82** Consider the complex ion  $[\text{CoF}_6]^{3-}$ .

- What is the geometry?
- Which is a more likely color for this ion to absorb, red or blue?
- Would you expect this complex to be high or low spin?

**22.83** What is the name of  $\text{K}_2[\text{MoOCl}_4]$ ?

**22.84** Write the formula and draw the structure of *cis*-tetraamminedichlorocobalt(III).

**22.85** You are studying an octahedral transition metal complex that contains the  $\text{Co}^{2+}$  ion and discover that it has a strong absorption in the blue region of the visible spectrum. Would you suspect (not conclude) that this complex is high spin or low spin. Explain?

**22.86** Consider the low-spin complex ions  $[\text{Cr}(\text{H}_2\text{O})_6]^{3+}$  and  $[\text{Mn}(\text{CN})_6]^{4-}$ .

- Name them.
- Determine the number of unpaired electrons.
- Indicate which complex ion would absorb the highest-frequency light.

**22.87** Is it possible to have a paramagnetic  $d^4$ -tetrahedral complex ion? Explain.

**22.88** Consider the tetracarbonyldibromoiron(II) ion.

- Write the chemical formula of the compound.
- How many geometric isomers are possible for this compound?

**22.89** Does the compound have optical isomers?

**22.89** Is the complex  $[\text{Mn}(\text{NH}_3)_6]^{2+}$  a low-spin or high-spin complex if it contains five unpaired electrons?

**22.90** For the low-spin complex  $[\text{Ru}(\text{NH}_3)_5\text{H}_2\text{O}]^{2+}$ , draw the crystal-field energy diagram. How many unpaired electrons are in the complex ion?

**22.91**  $[\text{Co}(\text{NH}_3)_6]^{3+}$  is diamagnetic, and  $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$  is paramagnetic.

- Name these complex ions.
- What is the geometry of these complex ions?
- Which of these ions has the greater crystal field splitting energy?

**22.92** Consult Figure 22.27, which depicts the absorption versus wavelength curve for the  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$  ion.

- What is the absorbance maximum (wavelength) of this ion?
- If you were to make the  $[\text{Ti}(\text{CN})_6]^{3-}$  ion, how would the absorption versus wavelength curve compare to that of the  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$  ion?
- How would the energy of the crystal field splitting of the  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$  and  $[\text{Ti}(\text{CN})_6]^{3-}$  compare?

## 23

## Organic Chemistry

Heating fibers made from organic compounds such as acetonitrile,  $\text{CH}_3\text{CN}$ , yield strong, lightweight carbon fibers, used in composite materials to manufacture the structural components of such things as cars, bicycles, and airplanes. The carbon in these fibers has a sheetlike structure similar to graphite, a carbon allotrope.

## CONTENTS AND CONCEPTS

**23.1** The Bonding of Carbon**Hydrocarbons**

*Hydrocarbons* are the substances that provide most of our energy needs and are the basis for many of the materials that we use every day. You will learn about

these molecules, as well as how to name them systematically.

**23.2** Alkanes and Cycloalkanes

**23.3** Alkenes and Alkynes

**23.4** Aromatic Hydrocarbons

**23.5** Naming Hydrocarbons

**Derivatives of Hydrocarbons**

We explore how the chemistry of hydrocarbons can be changed by the addition of *functional groups*.

**23.6** Organic Compounds Containing Oxygen

**23.7** Organic Compounds Containing Nitrogen

**O**rganic chemistry is the chemistry of compounds containing carbon. As discussed in Chapter 2, carbon-containing compounds make up the majority of known compounds. Organic chemistry plays a central role in most of the substances that you encounter and use every day: the food you ate this morning, the shampoo that cleans your hair, the fuel used to heat your house and generate electricity, and the list goes on. Also, your life and that of every living organism on earth depends on the chemical reactions of organic molecules.

In this chapter, we introduce this fascinating area of chemistry with a discussion of the structural features of organic molecules, nomenclature, and a few important chemical reactions.

### 23.1 The Bonding of Carbon

Because carbon is in Group 4A of the periodic table, it has four valence electrons. To fill its octet, it requires four additional electrons, which can be obtained through the formation of four covalent bonds. Carbon forms single, double, and triple bonds to achieve a filled octet. Therefore, the possible bonding combinations for carbon are as follows.

Recall from the VSEPR model (Chapter 10) that the molecular geometry around an atom is dictated by the number of regions of electron density. As we have seen, double and triple bonds count as one area of electron density; therefore, carbon can have a tetrahedral, trigonal planar, or linear geometry.

A unique feature of carbon is its ability to bond with other carbon atoms to form chains and rings of various lengths. Several other elements have limited ability to form such chains or rings of like atoms, but only carbon does this with more than a few atoms. Some petroleum-containing products, such as asphalt, consist of molecules with 30 or more carbon atoms bonded together; the molecules that make up polyethylene can have chains with thousands of carbon atoms bonded together (Figure 23.1).

**b** Polyethylene contains chains of many thousands of carbon atoms bonded together. Polyethylene is used to create a variety of familiar materials.

## ► Hydrocarbons

The simplest organic compounds are **hydrocarbons**, *compounds containing only carbon and hydrogen*. All other organic compounds—for example, those containing O, N, and the halogen atoms—are classified as being derived from hydrocarbons. At first glance, you might think that the hydrocarbons represent a very limited set of molecules; however, several hundred thousand molecules exist that contain only hydrogen and carbon atoms.

Hydrocarbons can be separated into three main groups:

1. **Saturated hydrocarbons** are *hydrocarbons that contain only single bonds between the carbon atoms*. Saturated hydrocarbon molecules can be *cyclic* or *acyclic*. A cyclic hydrocarbon is one in which a chain of carbon atoms has formed a ring. An acyclic hydrocarbon is one that does not contain a ring of carbon atoms.
2. **Unsaturated hydrocarbons** are *hydrocarbons that contain double or triple bonds between carbon atoms*.
3. **Aromatic hydrocarbons** are *hydrocarbons that contain benzene rings or similar features*.

The saturated and unsaturated hydrocarbons are often referred to as the *aliphatic* hydrocarbons (Figure 23.2).

### 23.2 Alkanes and Cycloalkanes

The **alkanes** are *acyclic saturated hydrocarbons*, and the **cycloalkanes** are *cyclic saturated hydrocarbons*. The simplest hydrocarbon, an alkane called methane, consists of one carbon atom to which four hydrogen atoms are bonded in a tetrahedral arrangement. You can represent methane by its *molecular formula*,  $\text{CH}_4$ , which gives the number and kind of atoms in the molecule, or by its *structural formula*, which shows how the atoms are bonded to one another

Note that the structural formula does not convey information about the three-dimensional arrangement of the atoms. To do this, you would need to draw the three-dimensional formula depicting the *molecular geometry* (see Figure 23.3).

Figure 23.2 ▲

Molecular models for the different hydrocarbons

Figure 23.3 ▲

**Models of methane,  $\text{CH}_4$**  *Top*: Space-filling model of methane. *Middle*: Ball-and-stick model of methane with bond angle. *Bottom*: Electrostatic potential map.

Methane is a very important molecule since it is the principal component of natural gas. In 2014, more than  $2.6 \times 10^{11}$  ft<sup>3</sup> of natural gas was consumed in the United States to supply heating, power generation, transportation, and industrial needs.

### The Alkane Series

The term *paraffin* comes from the Latin *parum affinis*, meaning “little affinity.” The alkanes do not react with many reagents.

The alkanes, also called *paraffins*, ◀ have the general formula  $C_nH_{2n+2}$ . For  $n = 1$ , methane, the formula is  $CH_4$ ; for  $n = 2$ ,  $C_2H_6$ ; for  $n = 3$ ,  $C_3H_8$ ; and so on. Note that the general formula conveys no information about how the atoms are connected. For now, we will assume that the carbon atoms are bonded together in a straight chain with hydrogen atoms completing the four required bonds to each carbon atom; these are called *straight-chain* or *normal* alkanes. The structural formulas for the first four straight chain alkanes are shown.

Because carbon atoms typically have four bonds, chemists often write the structures of the parts of organic compounds using **condensed structural formulas**, or **condensed formulas**, where the bonds around each carbon atom in the compound are not explicitly written. For example,

Condensed formulas of the first four alkanes ( $n = 1$  to 4) are

Note that the condensed formula of an alkane differs from that of the preceding alkane ( $n-1$ ) by a  $-CH_2-$  group. The alkanes constitute a **homologous series**, which is a series of compounds in which one compound differs from a preceding one by a fixed group of atoms. Members of a homologous series have similar chemical properties, and their physical properties change throughout the series in a regular way. Table 23.1 lists the melting points and boiling points of the first ten straight-chain alkanes ( $n = 1$  to  $n = 10$ ). ◀ Note that the melting points and boiling points generally increase in the series with an increase in the number of carbon atoms in the chain. This is a result of increasing intermolecular forces, which increase with molecular weight.

Formerly, the names of the straight-chain alkanes were distinguished from branched-chain isomers by the prefix *n-* for *normal*. This designation is still common (butane is called *n*-butane) but is not used in the IUPAC name, which we will discuss in Section 23.5.

### Constitutional Isomerism and Branched-Chain Alkanes

In addition to the straight-chain alkanes, *branched-chain* alkanes are possible. For example, isobutane (or 2-methylpropane) has the structure

Name	Number of Carbons	Formula	Melting Point (°C)	Boiling Point (°C)
Methane	1	CH <sub>4</sub>	-183	-162
Ethane	2	CH <sub>3</sub> CH <sub>3</sub>	-172	-89
Propane	3	CH <sub>3</sub> CH <sub>2</sub> CH <sub>3</sub>	-187	-42
Butane	4	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>2</sub> CH <sub>3</sub>	-138	0
Pentane	5	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>3</sub> CH <sub>3</sub>	-130	36
Hexane	6	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>4</sub> CH <sub>3</sub>	-95	69
Heptane	7	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>5</sub> CH <sub>3</sub>	-91	98
Octane	8	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>6</sub> CH <sub>3</sub>	-57	126
Nonane	9	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>7</sub> CH <sub>3</sub>	-54	151
Decane	10	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>8</sub> CH <sub>3</sub>	-30	174

Source: Based on Robert D. Whitaker et al., *Concepts of General, Organic, and Biological Chemistry*, p. 231. Copyright © 1981 by Houghton Mifflin Company.

Isobutane, C<sub>4</sub>H<sub>10</sub>, has the same molecular formula as butane, the straight-chain hydrocarbon. However, isobutane and butane have different structural formulas and, therefore, different molecular structures. Butane and isobutane are **constitutional** (or **structural**) **isomers**, *compounds with the same molecular formula but different structural formulas*. Figure 23.4 depicts molecular models of isobutane and butane. Because these isomers have different structures, they have different properties. For example, isobutane boils at -12°C, whereas butane boils at 0°C. Here the difference in boiling point can be attributed to the fact that isobutane has a more compact molecular structure than butane, which results in weaker intermolecular interactions between isobutane molecules.

The number of constitutional isomers rapidly increases with the number of carbons in the series. For example, there are three constitutional isomers with the molecular formula C<sub>5</sub>H<sub>12</sub> (pentanes; see Figure 23.5), five of C<sub>6</sub>H<sub>14</sub> (hexanes), and 75 of C<sub>10</sub>H<sub>22</sub> (decanes).

Branched alkanes are usually written using condensed structural formulas. The following example and exercise will help you make the transition to writing hydrocarbons in this way.

**Figure 23.4** ▲  
**Constitutional isomers of butane** Ball-and-stick models of isobutane (2-methylpropane) and butane.

**Figure 23.5** ▲  
**Isomers of pentane** Note that each isomer is a different compound with a different boiling point.

### Example 23.1 Writing Condensed Structural Formulas

#### Gaining Mastery Toolbox

##### Critical Concept 23.1

When writing the condensed structural formula of a hydrocarbon, the carbon–hydrogen bonds are not written.

Additionally, condensed structural formulas only contain written carbon–carbon bonds if explicitly writing the bonds conveys information about the structure.

##### Solution Essentials:

- Condensed structural formula
- Structural formula
- Hydrocarbon

Write the condensed structural formula of each of the following alkanes.

**Problem Strategy** A condensed structural formula is one in which as many of the explicit bonds (dashes) as possible are removed from the structural formula. The best way to proceed is to write the carbon backbone and then add in the additional atoms.

#### Solution

a. To write the condensed structural formula, it helps to identify the carbon backbone, or the skeleton of carbon atoms in the molecule. It is good practice to write the longest chain of carbon atoms in the molecule in a straight line. For this case, the skeleton looks like:

Next, write the appropriate number of H atoms next to each carbon atom.

Finally, find the straight chain(s) of carbon atoms that contain more than two carbon atoms and remove only the bonds (dashes) that connect those carbon atoms.

After a little practice you will be able to combine these steps.

b. Following the steps outlined above, the condensed structural formula for the molecule in part b is

Either of the above structures is correct; which structure you use depends on how much structural information you want to convey. Following the steps in the solution for part a, and recognizing that the  $-\text{CH}_2-\text{CH}_3$  fragment in the structure on the left is a chain of carbons, you should be able to arrive at the structure on the right.

**Answer Check** Check to see that the number and type of each of the atoms present in the condensed formula agree with the structural formula.

(continued)

**Example 23.1** (continued)

**Exercise 23.1** Write the condensed structural formula for the following alkane.

See Problems 23.27 and 23.28.

**Cycloalkanes**

The general formula for cyclic cycloalkanes is  $C_nH_{2n}$ . Figure 23.6 gives the names and structural formulas for the first four members of the cycloalkane series. In the condensed structural formulas, a carbon atom and its attached hydrogen atoms are assumed to be at each corner.

 **CONCEPT CHECK 23.1**

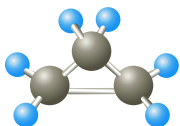

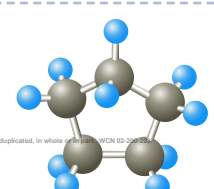

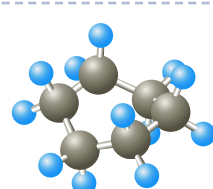

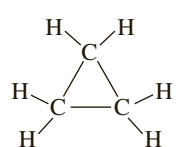

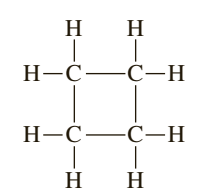

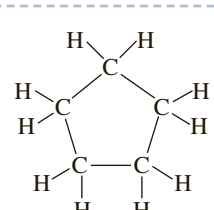

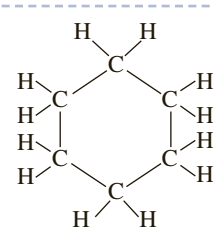

In the model shown here, C atoms are black and H atoms are light blue.

- Write the molecular formula.
- Write the condensed structural formula.

**Figure 23.6** ▼

**First four members of the cycloalkane series** These are saturated aliphatic hydrocarbons characterized by carbon-atom rings.

Name	CYCLOPROPANE	CYCLOBUTANE	CYCLOPENTANE	CYCLOHEXANE

## Sources and Uses of Alkanes and Cycloalkanes

Fossil fuels (natural gas, petroleum, and coal) are the principal sources of all types of organic chemicals. Natural gas is a mixture of low-molecular-weight hydrocarbons made up primarily of methane,  $\text{CH}_4$ , with lesser amounts of ethane,  $\text{C}_2\text{H}_6$ ; propane,  $\text{C}_3\text{H}_8$ ; and butane,  $\text{C}_4\text{H}_{10}$ . Petroleum, or crude oil, is the raw material extracted from a well. It is a mixture of alkanes and cycloalkanes with small amounts of aromatic hydrocarbons. The composition of petroleum is not consistent; it is dependent on geologic location and the organic matter present during oil formation. Because of this, a barrel of oil from Saudi Arabia contains a much different mixture of organic materials than a barrel of oil from the North Slope of Canada. The Saudi crude oil might be made up primarily of molecules with 5 to 20 carbon atoms, whereas the Canadian crude might consist mainly of molecules containing 20 to 40 carbon atoms. Crude oils that contain a majority of the lower-molecular-weight hydrocarbons are often more desirable because they are easier to transport and require less refining to convert to high-demand products like gasoline. Tables 23.2 and 23.3 show, respectively, the world's top oil producers and those with the largest reserves. Current world oil consumption is in excess of 90 million barrels per day.

Because fossil fuels are extracted from their source as mixtures of hydrocarbons, it is usually necessary to separate these mixtures into various components. Such separations are most easily performed by distilling the mixture into fractions that contain mixtures of compounds of different molecular weight. As you can see from Table 23.4, common names have been given to some of these fractions such as gasoline ( $\text{C}_5$  to  $\text{C}_{12}$ ) and kerosene ( $\text{C}_{12}$  to  $\text{C}_{15}$ ).

Often, there is a need to further separate the fractions listed in Table 23.4 into molecules with the same molecular weight, molecular formula, or structure.

**Table 23.4** Fractions from the Distillation of Petroleum

Boiling Range ( $^{\circ}\text{C}$ )	Name	Range of Carbon Atoms per Molecule	Use
Below 20	Gases	$\text{C}_1$ to $\text{C}_4$	Heating, cooking, and petrochemical raw material
20–200	Naphtha: straight-run gasoline	$\text{C}_5$ to $\text{C}_{12}$	Fuel; lighter fractions (such as petroleum ether, b.p. $30^{\circ}\text{C}$ – $60^{\circ}\text{C}$ ) are also used as laboratory solvents
200–300	Kerosene	$\text{C}_{12}$ to $\text{C}_{15}$	Fuel
300–400	Fuel oil	$\text{C}_{15}$ to $\text{C}_{18}$	Heating homes, diesel fuel
Over 400		Over $\text{C}_{18}$	Lubricating oil, greases, paraffin waxes, asphalt

Through chemical processes that usually involve catalysts, small molecules can be combined into larger molecules, and large molecules can be broken apart. The processing of petroleum via distillation or chemical reactions is called *petroleum refining*. The type and extent of the petroleum refining that is performed depend on the type of crude oil that is available and on the demand for a particular type of product. One chemical process, called *catalytic cracking*, involves passing hydrocarbon vapor over a heated catalyst of alumina ( $\text{Al}_2\text{O}_3$ ) and silica ( $\text{SiO}_2$ ) to break apart, or “crack,” high-molecular-weight hydrocarbons to produce hydrocarbons of low molecular weight. For example, this process can be used to convert the fuel oil fraction of petroleum to gasoline.

Petroleum refining also involves the conversion of the relatively abundant alkanes to unsaturated hydrocarbons, aromatic hydrocarbons, and hydrocarbon derivatives. The alkanes serve as the starting point for the majority of organic compounds, including plastics and pharmaceutical drugs. It is amazing to think about the number of everyday materials we use that started out as an alkane or cycloalkane (Figure 23.7).

Figure 23.7 ▲

**Consumer products derived from petroleum** All of these common items contain organic compounds that used petroleum as a starting material.

### Reactions of Alkanes with Oxygen

From your experiences with alkanes, it is probably apparent that they are not particularly reactive molecules at normal temperatures. But imagine if this were not the case; you would have to be extremely careful about how you filled your automobile with fuel, and you couldn't safely use natural gas in your home for heating or cooking. Also, the refining process could not involve the separation of the crude oil components at high temperatures by distillation. However, we do react alkanes every day through combustion with  $\text{O}_2$ ; all hydrocarbons burn (combust) in an excess of  $\text{O}_2$  at elevated temperatures to produce carbon dioxide, water, and heat. For example, a propane gas grill uses the reaction

The large negative  $\Delta H^\circ$  value for this reaction and all hydrocarbon reactions with oxygen demonstrates why we rely on these molecules to meet our energy needs.

### Substitution Reactions of Alkanes

Under the right conditions, alkanes can react with other molecules. An important example is the reaction of alkanes with the halogens  $\text{F}_2$ ,  $\text{Cl}_2$ , and  $\text{Br}_2$ . Reaction with  $\text{Cl}_2$ , for example, requires light (indicated by  $h\nu$ ) or heat.

This is an example of a substitution reaction. A **substitution reaction** is a reaction in which a part of the reacting molecule is substituted for an H atom on a hydrocarbon or hydrocarbon group. All of the H atoms of an alkane may undergo substitution, leading to a mixture of products.

The  $\text{CCl}_4$  product can be reacted with HF in the presence of a  $\text{SbCl}_5$  catalyst to produce trichlorofluoromethane,  $\text{CCl}_3\text{F}$ , also known as CFC-11.

This compound is one of a number of chlorofluorocarbons (CFCs) used for much of the twentieth century as a refrigerant. Data obtained in the 1970s revealed that these compounds survived long enough to travel to the stratospheric region of our atmosphere, where they facilitate the destruction of the ozone layer. (See the essay in Chapter 10 on this topic.) Recent refrigerants that do not as readily contribute to ozone destruction include hydrofluorocarbons (HFCs), such as  $\text{CF}_3\text{CH}_2\text{F}$ , which do not contain chlorine atoms. These HFCs are now used to replace CFCs.

### ✓ CONCEPT CHECK 23.2

For gasoline to function properly in an engine, it should not begin to burn before it is ignited by the spark plug. If it does, it makes the noise we think of as engine “knock.” The octane-number scale rates the anti-knock characteristics of a gasoline. This linear scale is based on heptane, given an octane number of 0, and on 2,2,4-trimethylpentane (an octane constitutional isomer), given an octane number of 100. The higher the octane number, the better the anti-knock characteristics. If you had a barrel of heptane and a barrel of 2,2,4-trimethylpentane, how would you blend these compounds to come up with a 90 octane mixture?

## 23.3 Alkenes and Alkynes

Alkenes and alkynes are unsaturated hydrocarbons. Because they contain carbon–carbon multiple bonds, they are typically much more reactive than alkanes.

Under the proper conditions, molecular hydrogen can be added to an alkene or alkyne to produce a saturated compound in a process called *catalytic hydrogenation*. For example, ethylene adds hydrogen to give ethane.

Catalytic hydrogenation is also used in the food industry to convert (hydrogenate) carbon–carbon double bonds to carbon–carbon single bonds. For example, margarine can be manufactured by hydrogenating some of the double bonds present in corn oil to change it from oil to a solid (fat).

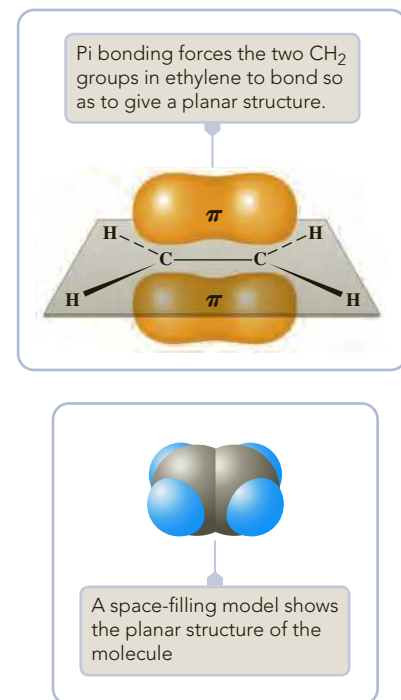

## Alkenes and Geometric Isomerism

**Alkenes** are hydrocarbons that have the general formula  $C_nH_{2n}$  and contain a carbon-carbon double bond. (These compounds are also called *olefins*.) The simplest alkene, ethylene, has the condensed formula  $CH_2=CH_2$  and the structural formula

Ethylene is a gas with a sweet odor. It is obtained from the refining of petroleum and is an important raw material in the chemical industry. For example, when ethylene molecules are linked they make polyethylene (see Section 23.1), which is commonly used to make soda bottles and milk jugs. Plants also produce small amounts of ethylene. Fruit suppliers have found that exposure of fruit to ethylene speeds ripening.

In ethylene and other alkenes, all of the atoms connected to the two carbon atoms of the double bond lie in a single plane, as Figure 23.8 shows. This is due to the need for maximum overlap of  $2p$  orbitals on the carbon atoms to form a pi ( $\pi$ ) bond. As a result, rotation about a carbon-carbon double bond cannot occur without breaking the  $\pi$  bond. For rotation to occur, a significant amount of energy must be supplied to break the  $\pi$  bond, so rotation does not normally occur. (This is in contrast to carbon-carbon single bonds, which have very low energy requirements for rotation and so freely rotate under most conditions.) This inability to rotate gives rise to geometric isomers in certain alkenes. **Geometric isomers** are isomers in which the atoms are joined to one another in the same way but differ because some atoms occupy different relative positions in space. For example, 2-butene,  $C_4H_8$ , has two geometric isomers, called *cis*-2-butene and *trans*-2-butene.

**Figure 23.8** ▲  
Representations of the ethylene molecule

The different boiling points confirm that they are different compounds. Note that in the *cis* isomer the two  $CH_3$  groups are attached to the same side of the double bond, whereas in the *trans* isomer the two  $CH_3$  groups are attached on opposite sides of the double bond. ► An alkene with the general formula

exists as geometric isomers only if groups A and B are different and groups C and D are different. For instance, geometric isomers do not exist for propene,  $CH_2=CHCH_3$ ,

As geometric isomers containing double bonds become more complicated than those presented here, they require a different set of naming rules to describe the geometries: the "E-Z system." For our purposes, using *cis* and *trans* to distinguish the isomers is sufficient.

### Example 23.2 Predicting *cis-trans* Isomers

#### Gaining Mastery Toolbox

##### Critical Concept 23.2

*Cis* and *trans* geometric isomers for alkenes can only occur when the groups bonded to the carbon atoms on each side of the double bond are different. This observation means that in every case in which two hydrogen atoms are bonded to a carbon atom on one side of a double bond, the geometry around the double bond in the molecule cannot lead to geometric isomers.

##### Solution Essentials:

- *Cis* and *trans* isomers
- Geometric isomer
- Alkene

For each of the following alkenes, decide whether *cis-trans* isomers are possible. If so, draw structural formulas of the isomers.

- a.  $\text{CH}_3\text{CH}_2\text{CH}=\text{C}(\text{CH}_3)_2$       b.  $\text{CH}_3\text{CH}=\text{CHCH}_2\text{CH}_3$

**Problem Strategy** In order to determine whether *cis-trans* isomers of the given compounds are possible, we need to draw the structural formula around the double bond. Then we compare the groups attached to the double bond; if the same groups are attached to the same side of the double bond, geometric isomers are not possible.

**Solution** a. Writing the structure, you have

Because two methyl groups are attached to the second carbon atom of the double bond, **geometric isomers are not possible.**      b. **Geometric isomers are possible.** They are

**Answer Check** When drawing the structural formula, make sure that you change only the special arrangement of the atoms, not the bonding.

**Exercise 23.2** Decide whether *cis-trans* isomers are possible for each of the following compounds. If isomers are possible, draw the structural formulas.

- a.  $\text{CH}_3\text{CH}=\text{CHCH}_2\text{CH}_2\text{CH}_3$       b.  $\text{CH}_3\text{CH}_2\text{CH}=\text{CH}_2$

See Problems 23.29 and 23.30.

*Cis* and *trans* isomers of dietary fats and oils are suspected to play a role in human health. All unprocessed fats and oils contain only *cis* isomers. During processing, some of the *cis* isomers are converted to *trans* isomers, called *trans* fatty acids. *Trans* fatty acids are suspected of raising the amount of serum cholesterol in the blood stream, which can cause health problems.

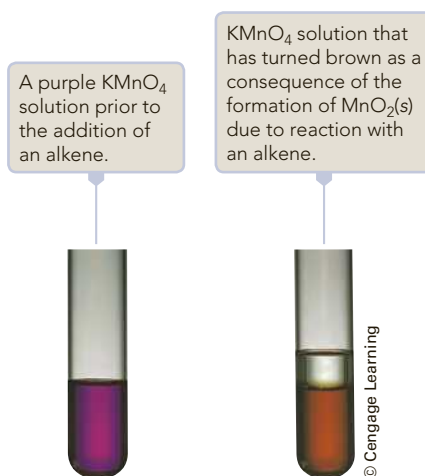

Figure 23.9 ▲

Test for unsaturation using  $\text{KMnO}_4(\text{aq})$

### Oxidation Reactions of Alkenes

Because alkenes are hydrocarbons, they undergo complete combustion reactions with oxygen at high temperatures to produce carbon dioxide and water. Unsaturated hydrocarbons can also be partially oxidized under relatively mild conditions. For example, when aqueous potassium permanganate,  $\text{KMnO}_4(\text{aq})$ , is added to an alkene (or alkyne), the purple color of  $\text{KMnO}_4$  fades and a brown precipitate of manganese dioxide forms (Figure 23.9).

## Addition Reactions of Alkenes

Alkenes are more reactive than alkanes because of the presence of the double bond. Many reactants *add* to the double bond. A simple example is the addition of a halogen, such as Br<sub>2</sub>, to propene.

An **addition reaction** is a reaction in which parts of a reactant are added to each carbon atom of a carbon–carbon double bond, which converts to a carbon–carbon single bond. (Addition to triple bonds is also possible, giving a product with a double bond.) The addition of Br<sub>2</sub> to an alkene is fast. In fact, it occurs so readily that bromine dissolved in carbon tetrachloride, CCl<sub>4</sub>, is a useful reagent to test for unsaturation. When a few drops of the solution are added to an alkene, the red-brown color of the Br<sub>2</sub> disappears immediately.

Unsymmetrical reagents, such as HCl and HBr, add to unsymmetrical alkenes to give two products that are constitutional isomers. For example,

and

In one case, the hydrogen atom of HBr adds to carbon atom 1, giving 2-bromopropane; in the other case, the hydrogen atom of HBr adds to carbon atom 2, giving 1-bromopropane. (The name 1-bromopropane means that a bromine atom is substituted for a hydrogen atom at carbon atom 1.) However, the two products are not formed in equal amounts; one is more likely to form. **Markownikoff's rule** is a generalization that states that the major product formed by the addition of an unsymmetrical reagent such as H–Cl, H–Br, or H–OH is the one obtained when the H atom of the reagent adds to the carbon atom of the multiple bond that already has the greater number of hydrogen atoms attached to it. In the preceding example, the H atom of HBr should add preferentially to carbon atom 1, which has two hydrogen atoms attached to it. The major product then is 2-bromopropane.

### Example 23.3 Predicting the Major Product of an Addition Reaction

#### Gaining Mastery Toolbox

##### Critical Concept 23.3

When naming hydrocarbons always start the process by determining the longest continuous chain of carbon atoms. In many instances, the longest chain of carbon atoms will consist of some of the carbon atoms on the straight chain as well as those on one of the branches.

##### Solution Essentials:

- Straight-chain alkanes (Table 23.5)
- Alkyl group names (Table 23.6)
- Rules for naming hydrocarbons
- Alkane
- Hydrocarbon

What is the major product of the following reaction?

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCH 03-200-203

**Problem Strategy** Because this is an addition reaction of an unsymmetrical reagent (HCl), apply Markownikoff's rule to predict the major product.

**Solution** One H atom is attached to carbon 3 and none to carbon 2. Therefore, the major product is

(continued)

**Example 23.3** (continued)

**Answer Check** When writing the structure of compounds that consist of carbon with only single bonds, such as the product here, check to make sure that each carbon has four bonds.

**Exercise 23.3** Predict the main product when HBr adds to

See Problems 23.35 and 23.36.

© Cengage Learning

**Figure 23.10** ▲

**Preparation of acetylene gas** Here acetylene is prepared by the reaction of water with calcium carbide. The acetylene burns with a sooty flame.

## Alkynes

**Alkynes** are *unsaturated hydrocarbons containing a carbon-carbon triple bond*. The general formula is  $C_nH_{2n-2}$ . The simplest alkyne is acetylene (ethyne), a linear molecule.

Acetylene is a very reactive gas that is used to produce a variety of other chemical compounds. It burns with oxygen in the oxyacetylene torch to give a very hot flame (about  $3000^\circ\text{C}$ ). Acetylene is produced commercially from methane.

Acetylene is also prepared from calcium carbide,  $\text{CaC}_2$ . Calcium carbide is obtained by heating calcium oxide and coke (carbon) in an electric furnace:

The calcium carbide is cooled until it solidifies. The carbide ion,  $\text{C}_2^{2-}$ , is strongly basic and reacts with water to produce acetylene (Figure 23.10).

The alkynes, like the alkenes, undergo addition reactions, usually adding two molecules of the reagent for each  $\text{C}\equiv\text{C}$  bond. The major product is the isomer predicted by Markownikoff's rule, as shown in the following reaction:

## 23.4 Aromatic Hydrocarbons

Aromatic hydrocarbons usually contain benzene rings: six-membered rings of carbon atoms with alternating carbon-carbon single and carbon-carbon double bonds. The electronic structure of benzene can be represented by resonance formulas. For benzene,

This electronic structure can also be described using molecular orbitals (Figure 23.11). In this description,  $\pi$  molecular orbitals encompass the entire carbon-atom ring, and the  $\pi$  electrons are said to be delocalized. Delocalization of  $\pi$  electrons means that the double bonds in benzene do not behave as isolated double bonds. Two condensed formulas for benzene are

where the circle in the formula at right represents the delocalization of the  $\pi$  electrons (and therefore the double bonds). Although you will often encounter benzene represented with alternating double and single bonds as shown on the left, the better representation is the one that indicates the bond delocalization. The space-filling model of benzene is shown in Figure 23.12.

Aromatic compounds are found everywhere. The term *aromatic* implies that compounds that contain a benzene ring have aromas, and this is indeed the case. Flavoring agents that can be synthesized in the laboratory or found in nature include the flavor and aroma of cinnamon, cinnamaldehyde, and the wintergreen flavor of candies and gum, methyl salicylate (Figure 23.13).

Benzene rings also exist in the pain relievers acetylsalicylic acid (aspirin), acetaminophen (Tylenol), and the illegal drug mescaline.

Figure 23.11 ▲

**The molecular orbitals of benzene** The sigma bond framework (in green) forms by the overlap of  $sp^2$  hybrid orbitals on each carbon atom; H atom 1s orbitals overlap these hybrid orbitals to form C—H bonds. Delocalized pi orbitals form by the overlap of carbon atom  $2p$  orbitals that are perpendicular to the plane of the molecule; they give orbitals with lobes above and below this plane. Only the lowest-energy pi orbital is shown (yellow).

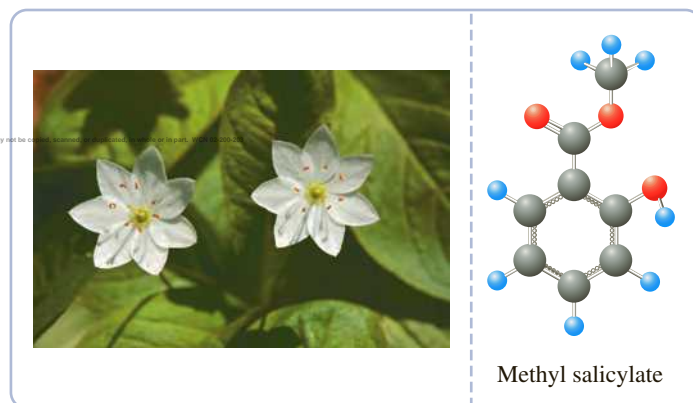

Figure 23.12 ▲

**Bond delocalization in benzene** The space-filling model of benzene shows that all carbon–carbon bond distances are identical.

Mescaline

Other examples include the active ingredients in some sunscreens: *p*-aminobenzoic acid (often abbreviated as PABA on the label) and oxybenzone.

*p*-Aminobenzoic acid  
(PABA)

Oxybenzone

Benzene rings can also fuse together to form polycyclic aromatic hydrocarbons in which two or more rings share carbon atoms. Figure 23.14 gives formulas for

Figure 23.14 ▶

**Some polycyclic aromatic hydrocarbons** Naphthalene is the simplest member of this series. It is a white, crystalline substance used in manufacturing plastics and plasticizers (to keep plastics pliable). Small amounts are used for mothballs.

some polycyclic aromatic hydrocarbons. Naphthalene is one of the compounds that gives mothballs their characteristic odor.

### Substitution Reactions of Aromatic Hydrocarbons

Although benzene,  $C_6H_6$ , is an unsaturated hydrocarbon, it does not usually undergo addition reactions because the delocalized  $\pi$  electrons of benzene are more stable than the localized  $\pi$  electrons. Because of this, benzene does not undergo an addition reaction with  $Br_2$  in carbon tetrachloride like alkenes do. The usual reactions of benzene are substitution reactions. For example, in the presence of an iron(III) bromide catalyst, a hydrogen atom on the benzene ring is substituted with a bromine atom.

Similarly, benzene undergoes substitution with nitric acid in the presence of sulfuric acid to give nitrobenzene.

## 23.5 Naming Hydrocarbons

A nomenclature for organic compounds has developed over the years as a way of understanding and classifying their structures. This nomenclature is now formulated in rules agreed upon by the International Union of Pure and Applied Chemistry (IUPAC).

### Nomenclature of Alkanes

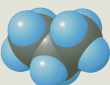

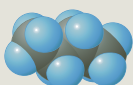

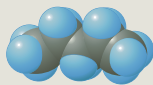

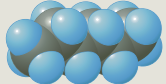

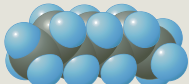

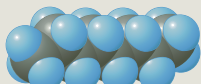

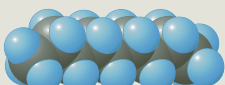

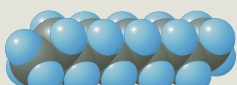

The first four straight-chain alkanes (methane, ethane, propane, and butane) have long-established names. Higher members of the series are named from the Greek words indicating the number of carbon atoms in the molecule, plus the suffix *-ane*. For example, the straight-chain alkane  $C_5H_{12}$  is named pentane. Table 23.5 gives the formulas, names, and structures of the first ten straight-chain alkanes.

The following four IUPAC rules are applied in naming the branched-chain alkanes:

1. Determine the longest continuous (not necessarily straight) chain of carbon atoms in the molecule. The base name of the branched-chain alkane is that of the straight-chain alkane (Table 23.5) corresponding to the number of carbon atoms in this longest chain. For example, in

the longest continuous carbon chain, shown in color, has seven carbon atoms, giving the base name heptane. The full name for the alkane includes the names of any branched chains. These names are placed in front of the base name, as described in the remaining rules.

Table 23.5 Formulas, Names, and Structures of the First Ten Straight-Chain Alkanes			
Name	Elemental Formula	Condensed Structural Formula	Molecular Model
Methane	CH <sub>4</sub>	CH <sub>4</sub>	
Ethane	C <sub>2</sub> H <sub>6</sub>	CH <sub>3</sub> CH <sub>3</sub>	
Propane	C <sub>3</sub> H <sub>8</sub>	CH <sub>3</sub> CH <sub>2</sub> CH <sub>3</sub>	
Butane	C <sub>4</sub> H <sub>10</sub>	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	
Pentane	C <sub>5</sub> H <sub>12</sub>	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	
Hexane	C <sub>6</sub> H <sub>14</sub>	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	
Heptane	C <sub>7</sub> H <sub>16</sub>	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	
Octane	C <sub>8</sub> H <sub>18</sub>	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	
Nonane	C <sub>9</sub> H <sub>20</sub>	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	
Decane	C <sub>10</sub> H <sub>22</sub>	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	

- Any chain branching off the longest chain is named as an alkyl group. An alkyl group is an alkane less one hydrogen atom. (Table 23.6 lists some alkyl groups.) When a hydrogen atom is removed from an end carbon atom of a straight-chain alkane, the resulting alkyl group is named by changing the suffix *-ane* of the alkane to *-yl*. For example, removing a hydrogen atom from methane gives the methyl group, —CH<sub>3</sub>. The structure shown in Rule 1 has a methyl group as a branch on the heptane chain.
- The complete name of a branch requires a number that locates the branch on the longest chain. For this purpose, you number each carbon atom on the longest

Original Alkane	Structure of Alkyl Group	Name of Alkyl Group
Methane, CH <sub>4</sub>	CH <sub>3</sub> —	Methyl
Ethane, CH <sub>3</sub> CH <sub>3</sub>	CH <sub>3</sub> CH <sub>2</sub> —	Ethyl
Propane, CH <sub>3</sub> CH <sub>2</sub> CH <sub>3</sub>	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> —	Propyl
Propane, CH <sub>3</sub> CH <sub>2</sub> CH <sub>3</sub>	$\begin{array}{c} \text{CH}_3\text{CHCH}_3 \\   \\ \text{---} \end{array}$	Isopropyl
Butane, CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	$\begin{array}{c} \text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{---} \\   \\ \text{---} \end{array}$	Butyl
Isobutane, CH <sub>3</sub> CHCH <sub>3</sub> $\begin{array}{c}   \\ \text{CH}_3 \end{array}$	$\begin{array}{c} \text{CH}_3\text{CCH}_3 \\   \\ \text{CH}_3 \end{array}$	<i>Tertiary</i> -butyl ( <i>t</i> -butyl)

chain in the direction that gives the smaller numbers for the locations of all branches. The structural formula in Rule 1 is numbered as shown:

The methyl branch is located at carbon 3 (not carbon 5) of the heptane chain. The complete name of the branch is 3-methyl, and the compound is named 3-methylheptane. Note that the branch name and the base name are written as a single word, and a hyphen follows the number.

4. When there are more than one alkyl branch of the same kind (say, two methyl groups), this number is indicated by a prefix, such as *di-*, *tri-*, or *tetra-*, used with the name of the alkyl group. The position of each group on the longest chain is given by numbers. For example,

Note that the position numbers are separated by a comma and are followed by a hyphen.

When there are two or more different alkyl branches, the name of each branch, with its position number, precedes the base name. The branch names are placed in alphabetical order. For example,

Note the use of hyphens.

**Example 23.5** (continued)**Solution Essentials:**

- Straight-chain alkanes (Table 23.5)
- Alkyl group names (Table 23.6)
- Rules for naming hydrocarbons
- Alkane
- Hydrocarbon

**Solution** First write the carbon skeleton for heptane.

Then attach the alkyl groups.

After filling out the structure with H atoms, you have

**Answer Check** Once you have written the structural formula of the compound, name it to see if you end up with the compound that you started with.

**Exercise 23.5** Write the condensed structural formula of 3,3-dimethyloctane.

See Problems 23.39 and 23.40.

**Nomenclature of Alkenes and Alkynes**

The IUPAC name for an alkene is determined by first identifying the longest chain containing the double bond. As with the alkanes, the longest chain provides the stem name, but the suffix is *-ene* rather than *-ane*. The carbon atoms of the longest chain are then numbered from the end nearer the carbon-carbon double bond, and the position of the double bond is given the number of the first carbon atom of that bond (the smaller number). This number is written in front of the stem name of the alkene. Branched chains are named the same way as the alkanes. The simplest alkene,  $\text{CH}_2=\text{CH}_2$ , is called ethene, although the common name is ethylene.

**Example 23.6** Writing the IUPAC Name of an Alkene Given the Structural Formula**Gaining Mastery Toolbox****Critical Concept 23.6**

Compounds that contain double bonds are named using the suffix *-ene*. Similar to alkanes, the longest carbon chain provides the stem name; however, in this case, the chain must contain the double bond.

**Solution Essentials:**

- Alkene
- Straight-chain alkanes (Table 23.5)
- Alkyl group names (Table 23.6)
- Rules for naming hydrocarbons
- Alkane
- Hydrocarbon

What is the IUPAC name of each of the following alkenes?

**Problem Strategy** The compounds in this problem contain double bonds, so they are alkenes. Naming these compounds is done in the same fashion as naming the alkanes, with one exception: the position of the double bond in each structure dictates that we number the longest carbon-atom chain by starting at the end of the chain nearest to the double bond.

(continued)

**Example 23.6** (continued)**Solution** a. The numbering of the carbon chain is

Because the longest chain containing a double bond has five carbon atoms, this is a pentene. It is a 1-pentene, because the double bond is between carbon atoms 1 and 2. The name of the compound is **3-methyl-1-pentene**. Note the placement of hyphens. If the numbering had been in the opposite direction, you would have named the compound as a 4-pentene. But this is unacceptable, because 4 is greater than 1. b. The numbering of the longest chain containing the double bond is

This gives the name **4-butyl-2-nonene**. There is a longer chain (of ten carbon atoms), but it does not contain the double bond.

**Answer Check** Here, again, make sure the names correctly lead back to the correct structural formulas.**Exercise 23.6** Give the IUPAC name for each of the following compounds.

See Problems 23.41 and 23.42.

Recall that some alkenes also exhibit *cis* and *trans* isomerism. In these cases, either *cis* or *trans* may be included as a prefix, separated by a hyphen, to the name.

Alkynes are named using the IUPAC rules in the same way as the alkenes, except that the stem name is determined from the longest chain that contains the carbon-carbon triple bond. The suffix for the stem name is *-yne*.

**Exercise 23.7** Write the condensed structural formula of 2,5-dimethyl-2-heptene.

See Problems 23.43 and 23.44.

**Exercise 23.8** Give the IUPAC names, including the *cis* or *trans* label, for each of the geometric isomers of  $\text{CH}_3\text{CH}_2\text{CH}=\text{CHCH}_2\text{CH}_3$ .

See Problems 23.45 and 23.46.

**Exercise 23.9** Give the IUPAC name for each of the following alkynes.

See Problems 23.47 and 23.48.

### Nomenclature of Aromatic Hydrocarbons

Simple benzene-containing hydrocarbons that have one group substituted on a benzene ring use the name *benzene* as the suffix and the name of the group as the prefix. For example, the following compound is named ethylbenzene.

When two groups are on the benzene ring, three isomers are possible. The isomers may be distinguished by using the prefixes *ortho-* (*o-*), *meta-* (*m-*), and *para-* (*p-*). For example,

A numbering system is also used to show the positions of two or more groups.

It is sometimes preferable to name a compound containing a benzene ring by regarding the ring as a group in the same manner as alkyl groups. Pulling a hydrogen atom from benzene leaves the phenyl group,  $C_6H_5-$ . For example, you name the following compound diphenylmethane by using methane as the stem name.

**Exercise 23.10** Write the structural formula of a. ethylbenzene; b. 1,2-diphenylethane.

See Problems 23.43 and 23.44.

#### ✓ CONCEPT CHECK 23.3

In the model shown here, C atoms are black and H atoms are light blue.

- Write the molecular formula.
- Write the condensed structural formula.
- Write the IUPAC name.

## ► Derivatives of Hydrocarbons

Certain groups of atoms in organic molecules are particularly reactive and have characteristic chemical properties. A **functional group** is a reactive portion of a molecule that undergoes predictable reactions. As discussed in Section 23.3, the C=C bond in a compound reacts readily and predictably with the reagents Br<sub>2</sub> and HBr in addition reactions. Thus, the C=C bond is a functional group. Many functional groups contain an atom other than carbon that has lone pair(s) of electrons. These lone pairs of electrons contribute to the reactivity of the functional group. Other functional groups, such as C=O, have multiple bonds that are reactive. Table 23.7 lists some common functional groups.

In the previous sections of the chapter, we discussed the hydrocarbons and their reactions. All other organic compounds can be considered to be derivatives of hydrocarbons. In these compounds, one or more hydrogen atoms of a hydrocarbon have been replaced by atoms other than carbon to give a functional group.

### 23.6 Organic Compounds Containing Oxygen

Many of the important functional groups in organic compounds contain oxygen. Examples are alcohols, ethers, aldehydes, ketones, carboxylic acids, and esters. In this section, we will look at the characteristics of these compounds.

Table 23.7 Some Organic Functional Groups

Structure of General Compound* (Functional Group in Color)	Name of Functional Group
$\text{R}-\overset{\cdot\cdot}{\underset{\cdot\cdot}{\text{Cl}}}: \quad \text{R}-\overset{\cdot\cdot}{\underset{\cdot\cdot}{\text{Br}}}: $	Organic halide
$\text{R}-\overset{\cdot\cdot}{\underset{\cdot\cdot}{\text{O}}}-\text{H}$	Alcohol
$\text{R}-\overset{\cdot\cdot}{\underset{\cdot\cdot}{\text{O}}}-\text{R}'$	Ether
$\begin{array}{c} \text{:O:} \\ \parallel \\ \text{R}-\text{C}-\text{H} \end{array}$	Aldehyde
$\begin{array}{c} \text{:O:} \\ \parallel \\ \text{R}-\text{C}-\text{R}' \end{array}$	Ketone
$\begin{array}{c} \text{:O:} \\ \parallel \\ \text{R}-\text{C}-\overset{\cdot\cdot}{\underset{\cdot\cdot}{\text{O}}}-\text{H} \end{array}$	Carboxylic acid
$\begin{array}{c} \text{:O:} \\ \parallel \\ \text{R}-\text{C}-\overset{\cdot\cdot}{\underset{\cdot\cdot}{\text{O}}}-\text{R}' \end{array}$	Ester
$\begin{array}{ccc} \text{R}-\overset{\cdot\cdot}{\underset{\cdot\cdot}{\text{N}}}-\text{H} & \text{R}-\overset{\cdot\cdot}{\underset{\cdot\cdot}{\text{N}}}-\text{H} & \text{R}-\overset{\cdot\cdot}{\underset{\cdot\cdot}{\text{N}}}-\text{R}'' \\   &   &   \\ \text{H} & \text{R}' & \text{R}' \end{array}$	Amine
$\begin{array}{c} \text{:O:} \\ \parallel \\ \text{R}-\text{C}-\overset{\cdot\cdot}{\underset{\cdot\cdot}{\text{N}}}-\text{R}' \\   \\ \text{H} \end{array}$	Amide

\*R, R', and R'' are general hydrocarbon groups.

## Alcohols and Ethers

Structurally, you may think of an **alcohol** as a compound obtained by substituting a hydroxyl group ( $\text{—OH}$ ) for an  $\text{—H}$  atom on a tetrahedral ( $sp^3$  hybridized) carbon atom of a hydrocarbon group. Some examples are

Alcohols are named by IUPAC rules similar to those for the hydrocarbons, except that the stem name is determined from the longest chain containing the carbon atom to which the  $\text{—OH}$  group is attached. The suffix for the stem name is *-ol*. The position of the  $\text{—OH}$  group is indicated by a number preceding the stem name. (The number is omitted if unnecessary, as in ethanol.)

Alcohols are usually classified by the number of carbon atoms attached to the carbon atom to which the  $\text{—OH}$  group is bonded. A *primary alcohol* has one such carbon atom, a *secondary alcohol* has two, and a *tertiary alcohol* has three. The following are examples:

Methanol, ethanol, ethylene glycol, and glycerol are some common alcohols. Methanol,  $\text{CH}_3\text{OH}$ , was at one time separated from the liquid distilled from saw-dust—hence the common name *wood alcohol*. It is a toxic liquid prepared in large quantities by reacting carbon monoxide with hydrogen at high pressure in the presence of a catalyst. It is used as a solvent and as the starting material for the preparation of formaldehyde. Ethanol is manufactured by the fermentation of glucose (a sugar) or by the addition of water to the double bond of ethylene. The latter reaction is carried out by heating ethylene with water in the presence of sulfuric acid.

Alcoholic beverages contain ethanol. Ethanol is also a solvent and a starting material for many organic compounds. It is mixed with gasoline and sold as gasohol, an automotive fuel (Figure 23.15). Ethylene glycol (IUPAC name: 1,2-ethanediol) and glycerol (1,2,3-propanetriol) are alcohols containing more than one hydroxyl group.

© Cengage Learning

**Figure 23.15** ▲

**Gasoline containing ethanol** The gasoline in this pump was formulated with ethanol. Ethanol is added to boost octane and oxygenate the fuel.

Polysters are discussed in Chapter 24.

Ethylene glycol is a liquid prepared from ethylene and is used as an antifreeze agent. It is also used in the manufacture of polyester plastics and fibers. ◀ Glycerol is a nontoxic, sweet-tasting liquid obtained from fats during the making of soap. It is used in foods and candies to keep them soft and moist.

Just as an alcohol may be thought of as a derivative of water in which one H atom of  $H_2O$  has been replaced by a hydrocarbon group, R, an **ether** is a compound formally obtained by replacing both H atoms of  $H_2O$  by the hydrocarbon groups R and R'.

Common names for ethers are formed from the hydrocarbon groups plus the word *ether*. For example,  $\text{CH}_3\text{OCH}_2\text{CH}_2\text{CH}_3$  is called methyl propyl ether. By IUPAC rules, the ethers are named as derivatives of the longest hydrocarbon chain. For example,  $\text{CH}_3\text{OCH}_2\text{CH}_2\text{CH}_3$  is 1-methoxypropane; the methoxy group is  $\text{CH}_3\text{O}-$ . The best-known ether is diethyl ether,  $\text{CH}_3\text{CH}_2\text{OCH}_2\text{CH}_3$ , often called simply ether, a volatile liquid used as a solvent and as an anesthetic.

**Exercise 23.11** Give the IUPAC name of the following compound.

See Problems 23.53 and 23.54.

**Exercise 23.12** Give the common name of each of the following compounds:

a.  $\text{CH}_3\text{OCH}_3$ ;    b.  $\text{CH}_3\text{OCH}_2\text{CH}_3$ .

See Problems 23.57 and 23.58.

### Aldehydes and Ketones

Aldehydes and ketones are compounds containing a *carbonyl group*. An **aldehyde** is a compound containing a carbonyl group with at least one H atom attached to it.

Here (H)R indicates a hydrocarbon group or H atom. The aldehyde function is usually abbreviated  $-\text{CHO}$ , and the structural formula of acetaldehyde is written  $\text{CH}_3\text{CHO}$ .

A **ketone** is a compound containing a carbonyl group with two hydrocarbon groups attached to it.

The ketone functional group is abbreviated  $-\text{CO}-$ , and the structural formula of acetone is written  $\text{CH}_3\text{COCH}_3$ .

Aldehydes and ketones are named according to IUPAC rules similar to those for naming alcohols. You first locate the longest carbon chain containing the carbonyl group to get the stem hydrocarbon name. Then you change the *-e* ending of the hydrocarbon to *-al* for aldehydes and *-one* for ketones. In the case of aldehydes,

Figure 23.16 ◀

**Some aldehydes of aromatic hydrocarbons** The name *aromatic* in aromatic hydrocarbons derives from the aromatic odors of many derivatives of these hydrocarbons, including the aldehydes shown here.

the carbon atom of the  $\text{—CHO}$  group is always the number-1 carbon. In ketones, however, the carbonyl group may occur in various nonequivalent positions on the carbon chain. For ketones, the position of the carbonyl group is indicated by a number before the stem name, just as the position of the hydroxyl group is indicated in alcohols. The carbon chain is numbered to give the smaller number for the position of the carbonyl group.

The aldehydes of lower molecular weight have sharp, penetrating odors. Formaldehyde (methanal),  $\text{HCHO}$ , and acetaldehyde (ethanal),  $\text{CH}_3\text{CHO}$ , are examples. With increasing molecular weight, the aldehydes become more fragrant. Some aldehydes of aromatic hydrocarbons have especially pleasant odors (see Figure 23.16). Formaldehyde is a gas produced by the oxidation of methanol. The gas is very soluble in water, and a 37% aqueous solution called Formalin is marketed as a disinfectant and as a preservative of biological specimens. The main use of formaldehyde is in the manufacture of plastics and resins. Acetone,  $\text{CH}_3\text{COCH}_3$ , is the simplest ketone. It is a liquid with a fragrant odor. The liquid is an important solvent for lacquers, paint removers, and nail polish removers.

**Exercise 23.13** Name the following compounds by IUPAC rules:

See Problems 23.59 and 23.60.

## Carboxylic Acids and Esters

A **carboxylic acid** is a compound containing the carboxyl group,  $\text{—COOH}$ .

These compounds are named by IUPAC rules like those for the aldehydes, except that the ending on the stem name is *-oic*, followed by the word *acid*. Many carboxylic acids have been known for a long time and are usually referred to by common names (see Table 23.8). The carboxylic acids are weak acids because of the acidity of the H atom on the carboxyl group. Acid-ionization constants are about  $10^{-5}$ .

An **ester** is a compound formed from a carboxylic acid,  $\text{RCOOH}$ , and an alcohol,  $\text{R'OH}$ . The general structure is

**Table 23.8** Common Carboxylic Acids

Carbon Atoms	Formula	Source	Common Name	IUPAC Name
1	HCOOH	Ants (Latin, <i>formica</i> )	Formic acid	Methanoic acid
2	CH <sub>3</sub> COOH	Vinegar (Latin, <i>acetum</i> )	Acetic acid	Ethanoic acid
3	CH <sub>3</sub> CH <sub>2</sub> COOH	Milk (Greek, <i>protos pion</i> , "first fat")	Propionic acid	Propanoic acid
4	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>2</sub> COOH	Butter (Latin, <i>butyrum</i> )	Butyric acid	Butanoic acid
5	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>3</sub> COOH	Valerian root (Latin, <i>valere</i> , "to be strong")	Valeric acid	Pentanoic acid
6	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>4</sub> COOH	Goats (Latin, <i>caper</i> )	Caproic acid	Hexanoic acid

### 23.7 Organic Compounds Containing Nitrogen

Alcohols and ethers, you may recall, can be considered derivatives of H<sub>2</sub>O, where one or both H atoms are replaced by hydrocarbon groups, R. Thus, the general formula of an alcohol is ROH, and that of an ether is ROR'. Another important class of organic compounds is obtained by similarly substituting R groups for the H atoms of ammonia, NH<sub>3</sub>.

Most organic bases are **amines**, which are *compounds that are structurally derived by replacing one or more hydrogen atoms of ammonia with hydrocarbon groups*.

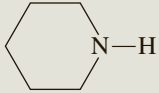

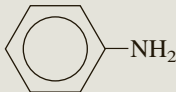

Table 23.9 lists some common amines.

Amines are bases, because the nitrogen atom has an unshared electron pair that can accept a proton to form a substituted ammonium ion. For example,

**Table 23.9** Some Common Amines

Name	Formula	Boiling Point °(C)
Methylamine	CH <sub>3</sub> —NH <sub>2</sub>	−6.5
Dimethylamine	$  \begin{array}{c} \text{CH}_3-\text{N}-\text{CH}_3 \\   \\ \text{H} \end{array}  $	7.4
Trimethylamine	$  \begin{array}{c} \text{CH}_3-\text{N}-\text{CH}_3 \\   \\ \text{CH}_3 \end{array}  $	3.5
Ethylamine	CH <sub>3</sub> CH <sub>2</sub> —NH <sub>2</sub>	16.6
Piperidine		106
Aniline		184

Source: Based on Robert D. Whitaker et al., *Concepts of General, Organic, and Biological Chemistry*. Copyright © 1981 by Houghton Mifflin Company.

Like ammonia, amines are weak bases. Table 16.2 gives base-ionization constants of some amines.

**Amides** are compounds derived from the reaction of ammonia, or of a primary or secondary amine, with a carboxylic acid. For example, when ammonia is strongly heated with acetic acid, they react to give the amide acetamide. ▶

Methylamine and acetic acid react to give *N*-methylacetamide.

The condensation to give an amide occurs under milder conditions if the ammonia or amine is reacted with the acid chloride, a derivative of the carboxylic acid obtained by replacing

In this reaction, HCl is a product.

## ✓ A Checklist for Review

### Summary of Facts and Concepts

*Organic compounds* are hydrocarbons or derivatives of hydrocarbons. Hydrocarbons contain only H and C atoms. The three main groups of hydrocarbons are *saturated hydrocarbons*, hydrocarbons with only single bonds between the carbon atoms; *unsaturated hydrocarbons*, hydrocarbons that contain double or triple bonds between carbon atoms; and *aromatic hydrocarbons*, hydrocarbons that contain a benzene ring (a six-membered ring of carbon atoms with alternating single and double carbon-carbon bonds described by resonance formulas).

The *alkanes* are *acyclic*, saturated hydrocarbons that form a *homologous series* of compounds, with the general formula  $\text{C}_n\text{H}_{2n+2}$ . The *cycloalkanes* are *cyclic*, saturated hydrocarbons that form another homologous series with the general formula  $\text{C}_n\text{H}_{2n}$  in which the carbon atoms are joined in a ring. The *alkenes* and *alkynes* are unsaturated

hydrocarbons (cyclic or acyclic) that contain carbon-carbon double or triple bonds.

The alkanes and aromatic hydrocarbons usually undergo *substitution reactions*. Alkenes and alkynes undergo *addition reactions*. *Markownikoff's rule* predicts the major product in the addition of an unsymmetrical reagent to an unsymmetrical alkene.

A *functional group* is a portion of an organic molecule that reacts readily in predictable ways. Important functional groups containing oxygen are *alcohols* (ROH), *aldehydes* (RCHO), *ketones* (RCOR'), and *carboxylic acids* (RCOOH). When a functional group is present in an organic compound, the compound is considered to be a *hydrocarbon derivative*. *Amines* are organic derivatives of ammonia. They react with carboxylic acids to give *amides*.

### Learning Objectives

#### 23.1 The Bonding of Carbon

- Describe the ways in which carbon typically bonds.
- Define *saturated hydrocarbon*, *unsaturated hydrocarbon*, and *aromatic hydrocarbon*.

### Important Terms

hydrocarbons  
saturated hydrocarbons  
unsaturated hydrocarbons  
aromatic hydrocarbons

#### 23.2 Alkanes and Cycloalkanes

- Define *alkane* and *cycloalkane*.
- Know the general formula of an alkane.
- Give examples of alkanes in a *homologous series*.
- Define *constitutional (structural) isomers*.
- Write the condensed structural formula. **Example 23.1**
- Know the general formula of cyclic *cycloalkanes*.
- State the source of alkanes and cycloalkanes.

alkanes  
cycloalkanes  
condensed structural formula  
homologous series  
constitutional (structural) isomer  
substitution reaction

## Questions and Problems

### Self-Assessment and Review Questions

**Key:** These questions test your understanding of the ideas you worked with in the chapter. These problems vary in difficulty and often can be used for the basis of discussion.

**23.1** Give the molecular formula of an alkane with 25 carbon atoms.

**23.2** Draw structural formulas of the five isomers of C<sub>6</sub>H<sub>14</sub>.

**23.3** Draw structural formulas of an alkane, a cycloalkane, an alkene, and an aromatic hydrocarbon, each with eight carbon atoms.

**23.4** Explain why there are two isomers of 2-butene. Draw their structural formulas and name the isomers.

**23.5** Draw structural formulas for the isomers of ethylmethylbenzene.

23.6 Fill in the following table.

Hydrocarbon	Source	Use
Methane		
Octane		
Ethylene		
Acetylene		

23.7 Give condensed structural formulas of all possible substitution products of ethane and  $\text{Cl}_2$ .

23.8 Define the terms *substitution reaction* and *addition reaction*. Give examples of each.

23.9 What would you expect to be the major product when two molecules of HCl add successively to acetylene? Explain.

23.10 Write the structure of propylbenzene. Write the structure of *p*-dichlorobenzene.

23.11 What is a functional group? Give an example and explain how it fits this definition.

23.12 An aldehyde contains the carbonyl group. Ketones, carboxylic acids, and esters also contain the carbonyl group. What distinguishes these latter compounds from an aldehyde?

23.13 Fill in the following table.

Compound	Source	Use
Methanol		
Ethanol		
Ethylene glycol		
Glycerol		
Formaldehyde		

23.14 Identify and name the functional group in each of the following.

- |   |                                    |   |  |
|---|------------------------------------|---|--|
| a | $\text{CH}_3\text{COCH}_3$         | b | $\text{CH}_3\text{OCH}_2\text{CH}_3$         |
| c | $\text{CH}_3\text{CH}=\text{CH}_2$ | d | $\text{CH}_3\text{CH}_2\text{COOH}$          |
| e | $\text{CH}_3\text{CH}_2\text{CHO}$ | f | $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$ |

23.15 How many isomers exist that have the formula  $\text{C}_4\text{H}_8$ ?

- a two    b three    c four    d five    e six

23.16 Which of the following could exist as a *cis-trans* isomer?

- e none of these

23.17 The correct formula for butane is

23.18 What is the correct IUPAC name for the following compound?

- a 4-heptenol

- b 3-methyl-2-pentanol

- c 4-pentanol

- d 4-heptanol

- e 1,3-diethyl-2-propanol

## Conceptual Problems

**Key:** These problems are designed to check your understanding of the concepts associated with some of the main topics presented in each chapter. A strong conceptual understanding of chemistry is the foundation for both applying chemical knowledge and solving chemical problems. These problems vary in level of difficulty and often can be used as a basis for group discussion.

23.19 You are distilling a barrel of oil that contains the hydrocarbons listed in Table 23.4. You heat the contents of the barrel to  $200^\circ\text{C}$ .

- What molecules will no longer be present in your sample of oil?
- What molecules will be left in the barrel?
- Provide an explanation for your answers in parts a and b.
- Which molecule would boil off at a lower temperature, hexane or 2,3-dimethylbutane?

23.20 A classmate tells you that the following compound has the name 3-propylhexane.

- Is he right? If not, what error did he make and what is the correct name?
- How could you redraw the condensed formula to better illustrate the correct name?

23.21 Explain why you wouldn't expect to find a compound with the formula  $\text{CH}_5$ .

23.22 Catalytic cracking is an industrial process used to convert high-molecular-weight hydrocarbons to low-molecular-weight hydrocarbons. A petroleum company has a huge supply of heating oil stored as straight-chain  $\text{C}_{17}\text{H}_{36}$ , and demand has picked up for shorter chain hydrocarbons to be used in formulating gasoline. The company uses catalytic cracking to create the shorter chains necessary for gasoline. If they produce two molecules in the cracking, and 1-octene is one of them, what is the formula of the other molecule produced? As part of your answer, draw the condensed structural formula of the 1-octene.

23.23 In the following four models, C atoms are black, H atoms are light blue, O atoms are red, and N atoms are dark blue:

- a Write the molecular formula of each molecule.  
 b Write the condensed structural formula for each molecule.  
 c Identify the functional group for each molecule.

23.24 In the models shown here, C atoms are black and H atoms are light blue:

- a Write the molecular formula of each molecule.  
 b Write the condensed structural formula for each molecule.  
 c Give the IUPAC name of each molecule.

23.25 Why would you expect the melting points of the alkanes to increase in the series methane, ethane, propane, and so on?

23.26 Consider the following formulas of two esters:

One of these is ethyl ethanoate (ethyl acetate) and one is methyl propanoate (methyl propionate). Which is which?

## Practice Problems

**Key:** These problems are for practice in applying problem-solving skills. They are divided by topic, and some are keyed to exercises (see the ends of the exercises). The problems are arranged in matching pairs; the odd-numbered problem of each pair is listed first, and its answer is given in the back of the book.

### Condensed Structural Formulas

23.27 Write the condensed structural formula of the following alkane.

23.28 Write the condensed formula of the following alkane.

### Geometric Isomers

23.29 If there are geometric isomers for the following, draw structural formulas showing the isomers.

23.30 One or both of the following have geometric isomers. Draw the structures of any geometric isomers.

### Reactions of Hydrocarbons

23.31 Complete and balance the following equations. Note any catalyst used.

**23.32** Complete and balance the following equations. Note any catalyst used.

Cyclohexene

**23.33** Write an equation for a possible substitution reaction of ethane,  $\text{C}_2\text{H}_6$ , with  $\text{Br}_2$ .

**23.34** Write an equation for a possible substitution reaction of butane,  $\text{C}_4\text{H}_{10}$ , with  $\text{Cl}_2$ .

**23.35** What is the major product when  $\text{HBr}$  is added to methylpropene?

**23.36** Complete the following equation, giving only the main product.

### Naming Hydrocarbons

**23.37** Give the IUPAC name for each of the following hydrocarbons.

**23.38** What is the IUPAC name of each of the following compounds?

**23.39** Write the condensed structural formula for each of the following compounds.

- a 2,5-dimethyloctane  
b 4-ethyl-2-methylheptane  
c 3-ethylheptane  
d 2,2,3,3-tetramethylpentane

**23.40** Write the condensed structural formula for each of the following compounds.

- a 2,2-dimethylpentane  
b 2-ethyl-2-methylhexane  
c 3-ethyl-2-methyloctane  
d 3,4,4,5-tetramethylheptane

**23.41** Give the IUPAC name of each of the following.

- a  $\text{CH}_3\text{CH}_2\text{CH}=\text{CH}-\text{CH}_2-\text{CH}_3$   
b  $\text{H}_3\text{C}-\underset{\text{CH}_3}{\text{C}}=\text{CH}-\underset{\text{CH}_3}{\text{CH}_2}-\text{CH}_2$

**23.42** For each of the following, write the IUPAC name.

- a  $\text{CH}_3\text{CH}_2-\underset{\text{CH}_3\text{CH}_2}{\text{C}}=\text{CHCH}_2\text{CH}_3$   
b  $\text{CH}_3\text{CH}_2\text{C}(\text{CH}_2\text{CH}_2\text{CH}_3)=\text{CH}_2$

**23.43** Give the condensed structural formula for each of the following compounds.

- a 3-ethyl-2-pentene      b 4-ethyl-2-methyl-2-hexene

**23.44** Write the condensed structural formula for each of the following compounds.

- a 2,3-dimethyl-2-hexene  
b 2-methyl-4-propyl-3-decene

**23.45** Give the IUPAC names and include the *cis* or *trans* label for each of the isomers of  $\text{CH}_3\text{CH}=\text{CHCH}_2\text{CH}_3$ .

**23.46** Give the IUPAC names and include the *cis* or *trans* label for each of the isomers of  $\text{CH}_3\text{CH}=\text{CHCH}_3$ .

**23.47** Give the IUPAC name of each of the following compounds.

**23.48** Write the IUPAC name of each of the following hydrocarbons.

**23.49** Write structural formulas for **a** 1,1,1-triphenylethane;

**b** *o*-ethylmethylbenzene.

**23.50** Write structural formulas for **a** 1,2,4-trimethylbenzene

**b** *o*-diethylbenzene.

### Naming Oxygen-Containing Organic Compounds

**23.51** Circle and name the functional group in each compound.

**23.52** Circle and name the functional group in each compound.

**23.53** Give the IUPAC name for each of the following.

**23.54** Write the IUPAC name for each of the following.

**23.55** State whether each of the following alcohols is primary, secondary, or tertiary.

**23.56** Classify each of the following as a primary, secondary, or tertiary alcohol.

**23.57** What is the common name of each of the following compounds?

**23.58** What is the common name of each of the following compounds?

**23.59** According to IUPAC rules, what is the name of each of the following compounds?

**23.60** Write the IUPAC name of each of the following compounds.

### Organic Compounds Containing Nitrogen

**23.61** Identify each of the following compounds as a primary, secondary, or tertiary amine, or as an amide.

**23.62** Identify each of the following compounds as a primary, secondary, or tertiary amine, or as an amide.

## General Problems

**Key:** These problems provide more practice but are not divided by topic or keyed to exercises. Odd-numbered problems and the even-numbered problems that follow are similar; answers to all odd-numbered problems except the essay questions are given in the back of the book.

**23.63** Give the IUPAC name of each of the following compounds.

**23.64** Give the IUPAC name of each of the following compounds.

**23.65** Write the structural formula for each of the following compounds.

**23.66** Write the structural formula for each of the following compounds.

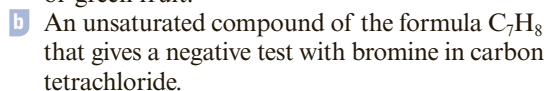

**23.67** Describe chemical tests that could distinguish between:

**23.68** Describe chemical tests that could distinguish between:

**23.69** Identify each of the following compounds.

**23.70** Identify each of the following compounds.

**23.71** A compound that is 85.6% C and 14.4% H and has a molecular weight of 56.1 amu reacts with water and sulfuric acid to produce a compound that reacts with acidic potassium dichromate solution to produce a ketone. What is the name of the original hydrocarbon?

**23.72** A compound with a fragrant odor reacts with dilute acid to give two organic compounds, A and B. Compound A is identified as an alcohol with a molecular weight of 32.0 amu. Compound B is identified as an acid. It can be reduced to give a compound whose composition is 60.0% C, 13.4% H, and 26.6% O and whose molecular weight is 60.1 amu. What is the name of the original compound?

## Strategy Problems

**Key:** As noted earlier, all of the practice and general problems are matched pairs. This section is a selection of problems that are not in matched-pair format. These challenging problems require that you employ many of the concepts and strategies that were developed in the chapter. In some cases, you will have to integrate several

concepts and operational skills in order to solve the problem successfully.

**23.73** For the following molecular model, where C atoms are black, H atoms are light blue, and oxygen is red:

b Write the IUPAC name.

23.74 For each of the following molecules, create the correct condensed structural formulas by adding and/or removing hydrogen atoms (do not add or remove bonds).

23.75 Name all of the functional groups present in the following molecule.

23.76 Draw the condensed structural formulas for a primary, a secondary, and a tertiary alcohol, each containing five carbon atoms.

23.77 For the following molecular model, where C atoms are black and H atoms are light blue:

a Write the molecular formula.

b Write the condensed structural formula.

c Write the IUPAC name.

23.78 Write the condensed structural formulas of a ketone and an ester, each containing four carbon atoms.

23.79 You encounter a hydrocarbon with the name 2-ethyl-3-methylhexane. Is this a proper IUPAC name? If not, what is the proper IUPAC name? To answer this question, start by writing the condensed structural formula based on this name.

23.80 Consider the molecule  $\text{CH}_3\text{CH}_2\text{CH}=\text{CHCH}_3$ .

a Write a structural formula of the *trans* isomer.

b Name the molecule from part a.

c Write the condensed structural formula of the major product of the reaction of the molecule with  $\text{Br}_2$ .

23.81 Give the IUPAC name of each of the following.

23.82 Write the condensed structural formula for each of the following.

a An aldehyde that contains five carbon atoms.

b An ether that contains four carbon atoms.

c An aromatic hydrocarbon with methyl groups at positions 1 and 5.

d A secondary amine that contains five carbon atoms.

e An alkyne that contains four carbon atoms.

23.83 Draw the structural formula of the following hydrocarbons.

a chlorobenzene

b 4-methyl-2-hexene

c *n*-octane

d For each answer (a–c), indicate if the molecule is saturated or unsaturated.

23.84 For each of the following, write the condensed structural formula of a molecule that fits the description. Add hydrogen atoms to complete the structure.

a An unsaturated alkene that contains five carbon atoms and one double bond.

b An aromatic hydrocarbon that contains six carbon atoms and two fluorine atoms.

c A saturated hydrocarbon that contains seven carbon atoms and one bromine atom at position number three on the carbon chain.

d A secondary amine.

23.85 Amino acids are important biological molecules. Using the name *amino acid* as a guide, write the name and structure of the functional groups common to all amino acids.

23.86 Draw the *cis* and *trans* isomers of the compound 3-methyl-3-hexene.

23.87 Indicate the molecular geometry around each carbon atom in the compound

23.88 Complete and balance the reaction for each of the following undergoing a combustion reaction.

a 2-methylpentane

b 2,2-dimethylpropane

c 3-methyl-3-hexene

d 3-ethyl-3-propanol

e ethylbenzene

## 24

# Polymer Materials: Synthetic and Biological

Pulling nylon from a reaction mixture. Nylon is formed from long, chainlike polymer molecules that line up with one another through intermolecular hydrogen bonding, resulting in a tough, fibrous material with applications ranging from fabrics to molded engineering products (such as gears).

Charles D. Winters

## CONTENTS AND CONCEPTS

### Synthetic Polymers

Polymers are chemical species of high molecular weight made up of many small repeating units. Synthetic polymers are used in many important products, such as plastics, polyurethane coatings, and nylon. Their syntheses have also helped scientists understand

the nature of polymers, including many natural materials.

**24.1** Synthesis of Organic Polymers

**24.2** Electrically Conducting Polymers

### Biological Polymers

The biological polymers include carbohydrates such as starch and

cellulose, proteins, and nucleic acids (DNA and RNA). We will look at the structure of proteins and nucleic acids in these sections.

**24.3** Proteins

**24.4** Nucleic Acids

**C**elluloid, discovered around 1850, was the first commercial plastic. Initially it was used as a cheap substitute for ivory in making billiard balls, but it soon became the material of choice for many consumer items such as combs and toothbrushes. Perhaps its best-known application, though, was in producing photographic film for motion pictures. Celluloid is a tough plastic, but it has one nasty property—it catches fire and burns explosively, a property that stems from celluloid's main ingredient, cellulose nitrate. Cellulose nitrate (also known as guncotton) is made by soaking a cellulose material such as cotton in a mixture of nitric and sulfuric acids. Soon after celluloid billiard balls came on the market, there were reports of billiard balls that vanished with a flash and a pop when touched accidentally by a person's cigar! There were also a number of serious theater fires. By the early twentieth century, celluloid was displaced in most of its applications by Bakelite, a hard plastic produced from formaldehyde, HCHO, and phenol, C<sub>6</sub>H<sub>5</sub>OH.

Plastics, such as celluloid and Bakelite, are *polymers*, which are giant molecules constructed by covalently bonding together many small molecules. The cellulose nitrate of celluloid is a chemically modified form of the natural polymer cellulose, which plants make from the sugar glucose C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>. Bakelite was the first completely synthetic polymer, produced commercially from non-polymeric chemicals. Since then, many different plastics with various properties have been developed (Figure 24.1).

In this chapter, we will look at some basic features of synthetic and biological, or natural, polymers. In the part concerning biological polymers, we will concentrate on proteins and how the genetic code, constructed from the polymer DNA, leads to the synthesis of proteins.

## ► Synthetic Polymers

A **polymer** is a chemical species of very high molecular weight made up from many units of low molecular weight covalently linked together. A compound used to make a polymer (and from which the polymer's unit arises) is called a **monomer**. A simple example is polyethylene, which consists of many ethylene units, —CH<sub>2</sub>CH<sub>2</sub>—, covalently bonded to one another to form long-chain molecules consisting of thousands of ethylene units. The name *polyethylene* stems from the name of the monomer (ethylene) plus the prefix *poly-*, meaning “many.” Shown here is a short piece of a polyethylene molecule.

One ethylene unit is shown in color.

Polyethylene is an example of a synthetic polymer, one made in the laboratory or commercially from nonpolymeric substances. We will look at synthetic polymers in the next two sections. The first polymers that chemists studied, however, were natural or biological polymers, including rubber, cellulose, starch, and proteins. Proteins and deoxyribonucleic acids (DNA) are polymers that form the basis of life on earth. We will examine these in the last part of the chapter.

## 24.1 Synthesis of Organic Polymers

The idea that certain natural products such as rubber are composed of giant molecules, or polymers, consisting of many repeating units linked by covalent bonds arose largely from the work of the German chemist Hermann Staudinger (1881–1965) in the early 1920s. His work ushered in an era of systematic study of polymers. Although chemists were initially skeptical of Staudinger's idea of giant molecules, the organic chemist Wallace Carothers proved this idea by using methods of organic chemistry to synthesize polymers (see the essay “The Discovery of Nylon” at the end of this section). Staudinger received the Nobel Prize in 1953 for his contributions to polymer chemistry.

It would be difficult to overemphasize the importance of synthetic polymers to present-day technology. Perhaps you are seated in front of a computer monitor, whose casing is made of hard plastic. The desk on which it sits probably has a coating of a polymer resin, such as polyurethane. Your clothing might well be made of fibers composed of synthetic polymers, such as polyester or nylon. And any elastic bands, such as those on your socks, are made from *elastomers*, an elastic or rubbery type of polymer.

In this section, we describe several synthetic polymers. Polymers are classified as *addition polymers* or *condensation polymers*, depending on the type of reaction used in forming them.

### Addition Polymers

An **addition polymer** is a polymer formed by linking together many molecules by addition reactions. The monomers must have multiple bonds that will undergo addition reactions. For example, when propylene (IUPAC name, propene) is heated under pressure with a catalyst, it forms polypropylene.

Note that the  $\pi$  electrons in the double bonds of the propylene molecules form new  $\sigma$  bonds that unite the monomers.

**Free-Radical Addition** The preparation of an addition polymer is often induced by an *initiator*, a compound that produces free radicals (species having an unpaired electron). Organic peroxides (organic compounds with the —O—O— group) are frequently used as initiators. If you write R for an organic group, the general formula of such a peroxide is R—O—O—R. When heated, the —O—O— bond in the organic peroxide breaks, and free radicals form. (The unpaired electron is symbolized by a dot.) Figure 24.2 illustrates the preparation of polystyrene using benzoyl peroxide as an initiator.

The free radical reacts with the alkene monomer to produce a new free-radical species, which in turn reacts with another monomer molecule. For example, the polymerization of propylene occurs as follows:

Figure 24.2 ▲

**Preparation of polystyrene** When styrene,  $\text{C}_6\text{H}_5\text{CH}=\text{CH}_2$ , is heated with a small amount of benzoyl peroxide,  $\text{ROOR}$  ( $\text{R} = \text{C}_6\text{H}_5\text{CO}-$ ), it yields a viscous liquid. After some time, this liquid sets to a hard plastic (sample shown at left).

**Table 24.1** Some Addition Polymers

Polymer	Monomer	Uses
Polyethylene	$\text{CH}_2=\text{CH}_2$	Bottles, plastic tubing
Polypropylene	$\begin{array}{c} \text{CH}_3 \\   \\ \text{CH}_2=\text{CH} \end{array}$	Bottles, carpeting, textiles
Polytetrafluoroethylene (Teflon <sup>®</sup> )	$\text{CF}_2=\text{CF}_2$	Nonstick surface for frying pans
Poly(vinyl chloride) (PVC)	$\begin{array}{c} \text{Cl} \\   \\ \text{CH}_2=\text{CH} \end{array}$	Plastic pipes, floor tile
Polyacrylonitrile (Orlon <sup>®</sup> , Acrilan <sup>®</sup> )	$\begin{array}{c} \text{CN} \\   \\ \text{CH}_2=\text{CH} \end{array}$	Carpets, textiles
Polystyrene (Styrofoam)	$\begin{array}{c} \text{C}_6\text{H}_5 \\   \\ \text{CH}_2=\text{CH} \end{array}$	Plastic foam insulation, cups

At each addition step, the unpaired electron from the free radical pairs with one of the  $\pi$  electrons of the alkene monomer to form a  $\sigma$  bond. One end of the chain retains an unpaired electron and can add another monomer molecule. The reaction terminates when the free electron at the end of the chain reacts with another free radical. Some addition polymers are listed in Table 24.1.

**Natural and Synthetic Rubber** Natural rubber is an addition polymer of isoprene (formal name, 2-methyl-1,3-butadiene). Rubber has been reproduced in the laboratory by heating isoprene with a catalyst:

Rubber is obtained from the milky sap, or latex, of the rubber tree (Figure 24.3). After the latex is collected, it is coagulated by the addition of formic or acetic acid.

The elasticity of rubber results from its long, coiled polymer chains. When you stretch a piece of rubber, the long coils unwind. When you let go, the molecules move back to roughly their original positions. Actually, the molecular strands do move relative to one another, which accounts for rubber's pliability and tackiness. Early rubber goods were sticky in the summer and brittle in the winter. In 1839, Charles Goodyear discovered that crude rubber heated with sulfur remained elastic but lacked these undesirable characteristics. Goodyear's process, called *vulcanization*, results in cross-linking of the polymer chains, which anchors them relative to one another.

Natural rubber is a **homopolymer**, a polymer whose monomer units are all alike. Most of the plastics we discussed earlier are also homopolymers. On the other hand,

**Collecting rubber latex** The outer bark of the rubber tree (*Hevea brasiliensis*) and the layer just beneath it are cut diagonally so that the latex runs into a collecting cup.

## Materials

A CHEMIST Looks at . . .

## The Discovery of Nylon

The announcement in October 1938 of the discovery of nylon, the first completely synthetic fiber, and the imminent production of nylon stockings was a momentous occasion. The press was fascinated by a fiber described as “strong as steel” and made from nothing more than coal, air, and water. And the public was eager to see stockings made from a fiber that it thought, being as strong as steel, must last forever. From our perspective, the discovery of nylon was important because it was the beginning of the synthetic polymers industry. Its discovery also established the study of polymers as a basic science.

Wallace Hume Carothers (Figure 24.4), the discoverer of nylon, was 31 years old in 1928 when he left Harvard University for the DuPont Company. (He had obtained his Ph.D. four years earlier in organic chemistry at the University of Illinois.) DuPont had decided to establish a group devoted to fundamental research, an idea that was rather novel at the time. The plan was that Carothers would work in an area that, though potentially useful to the company, did not have to have immediate commercial application.

Carothers proposed to work on the structure of materials like rubber, silk, and wool. The German chemist Hermann Staudinger had earlier suggested that these materials were actually macromolecules (that is, huge molecules) consisting of long chains of similar groups of atoms (in other words, polymers). At the time, most chemists thought that these materials were composed

AP Images

Figure 24.4 ▲

Wallace Carothers Discoverer of nylon.

of aggregates of many small molecules held together by some unknown force that was different from the normal forces of chemical bonding.

Carothers felt that he could determine the truth of Staudinger's view by using the methods of organic chemistry to synthesize (or build up) macromolecules in such a way as to establish their structure. He had a simple but brilliant idea.

To understand Carothers's idea, consider two functional groups, such as a carboxylic acid group ( $-\text{COOH}$ ) and an alcohol group ( $\text{HO}-$ ), that chemically link together. We can write a reaction between two compounds containing these groups forming an ester (Ch. 23) this way:

Even more simply, we can represent the linking of functional groups, such as a carboxyl group and an alcohol (or amine) group, as the linking of a hook and eye (the functional groups).

Now suppose we find a molecule having two of the same functional groups (such as two carboxyl groups) at the ends of the molecule; this would be the equivalent of a molecule with hooks at both ends. Then the reaction of several such molecules would result in a larger molecule.

With many such molecules, the product would be a long-chain molecule—a macromolecule. Carothers felt that if he could synthesize such a macromolecule with the properties of a textile fiber, he could establish the basis for further study of natural polymers, and he could go on to develop synthetic polymers (such as nylon) with improved properties.

Carothers's first macromolecule of this type was a polyester prepared from two different molecules, a dicarboxylic acid (a molecule with two carboxylic acid groups) and a dialcohol (two alcohol groups). The product, although interesting, tended to decompose in hot water and had a

(continued)

**Polyamides** When a compound containing two amine groups reacts with a compound containing two carboxylic acid groups, a condensation polymer called a *polyamide* is formed (Figure 24.5). Nylon-6,6 is an example. It is prepared by heating hexamethylene diamine (1,6-diaminohexane) and adipic acid (hexanedioic acid).

## 24.2 Electrically Conducting Polymers

Sometime during the early 1970s, a graduate student in the laboratory of Professor Hideki Shirakawa in Japan mistakenly added 1000 times too much catalyst in a reaction to polymerize acetylene to polyacetylene. (The basic reaction is similar to the one in which ethylene is polymerized to polyethylene; see the previous section.) To his surprise, the plastic film coating the inside of the vessel, which in previous experiments was black, now had a silvery sheen to it. The silvery film was *trans*-polyacetylene, which has the following Lewis resonance formulas:

The immediate question was this: If it looks like a metal, does it conduct electricity? In fact, the material had the electrical conductivity of a pure semiconductor, which is to say it was slightly conducting.

You can explain the slight conductivity of polyacetylene from its electronic structure. The Lewis resonance formulas of the long-chain molecule have alternating double and single bonds, indicative of delocalized bonding. In a molecular orbital description, the orbitals would encompass the entire length of the molecular chain. Thus, an electron would be able to move easily from one end of the molecule to the other, which means a current could travel the length of the molecule. Pure polyacetylene plastic is only slightly conductive, however, because electric current does not easily pass from one molecule to another.

Sometime later, Shirakawa collaborated with two scientists from the United States, Alan MacDiarmid, a chemist, and Alan Heeger, a physicist. MacDiarmid and Heeger had been doing experiments in which they “doped” (added small amounts of particular substances to) an inorganic polymer to increase its electrical conductivity. In experiments in 1977 with polyacetylene, they found that the electrical conductivity of the material increased dramatically when it was doped with iodine, I<sub>2</sub>.

How does doping increase the conductivity of the polymer? Polyacetylene consists of entwined strands of individual polymer molecules. Experiments show that iodine inserts itself between polyacetylene molecules, where it forms triiodide ion, I—I—I<sup>-</sup>. Each ion carries a negative charge that was abstracted from a π orbital of the polymer molecule. The polymer molecule is left with a positive charge, or

**Figure 24.5** ▲

**Nylon being pulled from a reaction mixture** Nylon is formed by reacting an aqueous solution of hexamethylene diamine (bottom layer) with adipic acid or, as in this experiment, with adipoyl chloride, ClCO(CH<sub>2</sub>)<sub>4</sub>COCl, dissolved in hexane (top layer). Nylon, formed at the interface of the two layers, is continuously removed.

Figure 24.6 ▶

**Movement of charge in polyacetylene**

The diagram shows the movement of electrons by arrows. When an electron moves away from the polymer chain (perhaps going to an electrode) at the far right, it leaves a hole, or positive charge, in the double bond. An electron from the adjacent double bond can then move into this hole, leaving a hole further to the left. In this way, the hole moves right to left. The triiodide ion facilitates electron transfer between the polymer chains. (Hydrogen atoms in polyacetylene were omitted for clarity.)

“hole.” The triiodide ion can facilitate the movement of an electron from an uncharged polymer molecule to a positively charged polymer molecule (a hole). In effect, the hole moves (Figure 24.6). The movement of holes through the material constitutes an electric current. Doped polyacetylene was only the first conductive polymer material to be discovered. Since 1977, other conducting polymers have also been developed (Figure 24.7).

During experiments to find alternative ways of doping polymers, a graduate student of Professor MacDiarmid discovered one of the first practical applications of polyacetylene. He placed two strips of polyacetylene into a solution of doping ions and applied an electric potential across the strips. The hope was that the ions would penetrate the polymer under the action of the external electric current. But after the student removed the external electric current, the polymer strips retained a charge and acted as a battery. Since then, an all-plastic battery has been developed. Its electrodes are made of conductive polymers, and the electrolyte is a polymer gel.

Scientists have succeeded in making various electronic devices, including transistors and light-emitting diodes (LEDs), from conducting polymers. Commercial

Figure 24.7 ▶

**Other conducting polymers**

Polypyrrole has been used in the construction of an all-plastic battery. Polyaniline has become a popular conducting polymer.

applications are just now coming to market. A conductive polymer acting as an LED is being used in displays for mobile phones and TVs. Alan Heeger, Alan MacDiarmid, and Hideki Shirakawa won the Nobel Prize in chemistry for the year 2000 for their discovery and development of conductive polymers.

Plastics have traditionally been thought of as insulators. In fact, electric wires are generally covered with a coating of polyethylene insulation. Now, some plastics have been found to be as conductive as metals. In chemistry, as in most other contexts, it pays to keep an open mind!

## ► Biological Polymers

The molecules of biological organisms fall into four groups: proteins, carbohydrates, nucleic acids, and lipids (nonpolymeric materials soluble in organic solvents, such as fats and oils). Proteins and nucleic acids, and many carbohydrates, are polymers. In this chapter, we will limit our discussion to proteins and nucleic acids. Proteins are the basic constituents of living organisms; we discuss these substances in the next section. Nucleic acids are important in the biological synthesis of proteins; we discuss these in the final section of the chapter.

### 24.3 Proteins

**Proteins** are *biological polymers of small molecules called amino acids*. Their molecular weights range from about 6000 amu to 250,000 amu, so proteins can be very large molecules. Many proteins also contain non-amino-acid components such as metal ions (for example,  $\text{Fe}^{2+}$ ,  $\text{Zn}^{2+}$ ,  $\text{Cu}^+$ , and  $\text{Mg}^{2+}$ ) or certain complex organic molecules usually derived from vitamins. (Vitamins are organic molecules necessary in very small quantities for normal cell structure and metabolism.)

Proteins are very important molecules in cells and organisms, playing both structural and functional roles. The proteins of bone and connective tissue, for example, are of major structural importance. Some proteins are enzymes, catalyzing specific biochemical reactions; some transport materials in the blood stream or across biological membranes; and some (hormones) carry chemical messages to coordinate the body's activities. *Insulin* and *glucagon*, for example, are protein hormones made in the pancreas and secreted to regulate the body's blood-sugar level.

#### Amino Acids

An **amino acid** is a compound containing an amino group ( $-\text{NH}_2$ ) and a carboxyl group ( $-\text{COOH}$ ). The building blocks of proteins are alpha-amino acids ( $\alpha$ -amino acids). An  $\alpha$ -amino acid has the general structure

The carbon atom next to the carboxyl carbon is called the  $\alpha$  carbon atom. In an  $\alpha$ -amino acid the amino group is attached to the  $\alpha$  carbon atom. Glycine,  $\text{NH}_2\text{CH}_2\text{COOH}$ , is the simplest  $\alpha$ -amino acid; R is an H atom.

Table 24.2 lists the 20 amino acids from which most proteins are composed. Under the name of each amino acid, its common three-letter abbreviation is shown. For instance, the abbreviation for glycine is gly.

Table 24.2 The Amino Acids Found in Most Proteins

			$\begin{array}{c} \text{COOH} \\   \\ \text{H}_2\text{N}-\text{C}-\text{H} \\   \\ \text{CH}_2 \\   \\ \text{C}(\text{NH}_2)_2 \\   \\ \text{NH} \\   \\ \text{C} \\ / \quad \backslash \\ \text{H} \quad \text{NH}_2 \end{array}$ <p>L-Arginine arg</p>

Each amino acid has a different R group, or *side chain*. The side chains of the amino acids in a protein determine the protein's properties. In Table 24.2, the side chains of the amino acids are shown within a color screen. Nine of the amino acids have nonpolar, or hydrocarbon, side chains (left side of table). The remaining 11 amino acids have polar side chains (right side of table), capable of ionizing or forming hydrogen bonds with other amino acids or with water.

At the near-neutral pH of a biological system, the amino acid groups in a protein are generally in the form of *zwitterions*, which are species having both a positive and a negative charge. The carboxyl group is acidic, so its proton ionizes:

The amino group is basic, so it tends to pick up a proton:

At neutral pH, the net result is that the carboxyl group loses  $\text{H}^+$  to the amino group, yielding the zwitterion:

Except for the simplest  $\alpha$ -amino acid, glycine,  $\text{NH}_2\text{CH}_2\text{COOH}$ , the  $\alpha$ -amino acids exist as *enantiomers*, or optical isomers. Such isomers are mirror images. Any molecule having one tetrahedral carbon atom bonded to four different groups of atoms exhibits optical isomerism. The mirror-image isomers are referred to as the L-isomer and the D-isomer; their three-dimensional structures are depicted here: ►

Optical isomerism is discussed in Section 22.5.

In these three-dimensional perspective formulas, a solid wedge is a bond pointing outward from the page, the hatched wedge is a bond pointing backward, and the straight line is a bond lying in the plane of the page. For instance, in the L-amino acid, the  $-\text{COOH}$  group and  $\text{H}_2\text{N}-$  groups are in the plane, the  $\text{R}-$  group points toward you, and the  $\text{H}$  atom points backward. All of the amino acids that occur naturally in proteins are L-amino acids.

The amino acids in a protein are linked together by peptide bonds. A **peptide** (or **amide**) **bond** is the  $\text{C}-\text{N}$  bond resulting from a condensation reaction between the carboxyl group of one amino acid and the amino group of a second amino acid:

The product in this example is a *dipeptide*, a molecule formed by linking together two amino acids. Similarly, a *tripeptide* is formed by linking together three amino acids. A **polypeptide** is a *polymer formed by the linking of many amino acids by peptide bonds*. It may or may not have a biological function. A *protein* is a polypeptide that has a biological function.

### CONCEPT CHECK 24.1

Two common amino acids are

Write the structural formulas of all the dipeptides that they could form with each other.

### Protein Primary Structure

The **primary structure** of a protein refers to *the order, or sequence, of the amino-acid units in the protein*. This order of amino acids is conveniently shown by denoting the amino acids by their three-letter abbreviations, separated by a dash. In this notation, it is understood that the amino group is on the left and the carboxyl group is on the right. For example, one possible dipeptide formed from alanine and glycine is written ala-gly.

Consider a polypeptide containing the following five amino-acid units: glycine, alanine, valine, histidine, and serine. These five units can be ordered in many different ways to make a polypeptide. Three possible primary structures are

gly-ser-ala-val-his

his-ala-ser-val-gly

ser-ala-gly-his-val

Each of the possible sequences would produce a different polypeptide with different properties.

In any protein, which may contain as few as 50 or more than 1000 amino-acid units, the amino acids are arranged in one unique sequence, which constitutes the primary structure of that protein molecule. Figure 24.8 diagrams the primary structure of proinsulin, the precursor to the hormone insulin.

### Shapes of Proteins

A protein molecule of a unique amino-acid sequence spontaneously folds and coils into a characteristic three-dimensional conformation in aqueous solution (Figure 24.9). The side chains of the amino-acid units, with their different

**Figure 24.8** ▲

**Primary structure of human proinsulin** *Left:* The diagram shows the order of the amino acids in the structure of the protein molecule proinsulin. Also shown are the positions of three disulfide linkages (discussed below). *Right:* The actual three-dimensional shape of the molecule is shown (the green ribbon follows the peptide backbone of the protein).

chemical properties (nonpolar or polar), determine the characteristic shape of the protein. For an energetically stable shape, the parts of the chain with nonpolar amino-acid side chains are buried within the structure away from water, because nonpolar groups are hydrophobic (not attracted to water). Conversely, most polar groups are stablest on the surface, where they can hydrogen-bond with water or with other polar side chains. Occasionally, side chains form ionic bonds.

One type of covalent linkage, *the disulfide linkage* ( $-\text{S}-\text{S}-$ ), is especially important to protein shape. The amino acid cysteine, with its thiol ( $-\text{SH}$ ) side chain, is able to react with a second cysteine in the presence of an oxidizing agent, as follows:

When two cysteine side chains in a polypeptide are brought close together by folding of the molecule and then are oxidized, they form a disulfide linkage, which helps anchor the folded chain into position (Figure 24.8).

Proteins may be classed as fibrous or globular on the basis of their arrangements in space. **Fibrous proteins** are *proteins that form long coils or align themselves in parallel to form long, water-insoluble fibers. The relatively simple coiled or parallel arrangement of a protein molecule is called its secondary structure* (Figure 24.10). **Globular proteins** are *proteins in which long coils fold into compact, roughly spherical shapes.* In addition to their secondary structure (long coil), globular proteins have a **tertiary structure**, or *structure associated with the way the protein coil is folded.* Most globular proteins are water soluble, because they are relatively small and have hydrophilic (“water-loving”) surfaces that bind water molecules.

**Figure 24.9** ▲

**Three-dimensional structure of myoglobin** Myoglobin is present in muscle tissue, and is a reservoir for  $\text{O}_2$ . In this model, the green ribbons are drawn to follow the backbone of the polypeptide chain. Note the coiled structure, which results from hydrogen bonding. The coiled sections fold so that the nonpolar side chains are inside the globular molecule, and the polar side chains point outward.

Figure 24.10 ►

**Protein secondary structures**

The alpha helix (coiled structure) and beta sheet, formed by hydrogen bonding between long polypeptide fibers or strands, are common secondary structures.

The characteristic coiling or folding pattern of protein molecules produces unique surface features, such as grooves or indentations, and hydrophobic or charged areas. These surface features are fundamental to protein function. They allow protein molecules to interact with other molecules in specific ways. For example, certain protein molecules characteristically aggregate because of complementary surface features, forming tubules or filaments or other organized structures. Particular surface features of enzyme molecules are responsible for their ability to bind specific molecules and catalyze specific reactions. The surface feature of an enzyme where catalysis occurs is referred to as its *active site* (Figure 24.11). Enzyme catalysis is discussed in Section 13.9. ◀

Some human disorders occur when, for some reason, protein molecules misfold, often forming fibrous proteins. Alzheimer's disease is thought to be such a disorder.

## 24.4 Nucleic Acids

*Nucleic acids* are vital to the life cycles of cells, because they are the carriers of species inheritance. There are two types of nucleic acids: *deoxyribonucleic acid (DNA)* and *ribonucleic acid (RNA)*. Both are polymers of *nucleotide* building blocks. ◀

### Sugar Constituents of Nucleic Acid

The building blocks of nucleic acids are themselves composed of certain organic bases linked to either ribose or deoxyribose, both of which are sugar molecules. In this short subsection, we will briefly discuss the structure of *monosaccharides*, or sugars, before we launch into the structure of nucleic acids.

Monosaccharides are simple sugars, each containing three to nine carbon atoms, generally all but one of which bear a hydroxyl group. The remaining carbon atom is part of a carbonyl group, either an aldehyde or a ketone. The monosaccharides exist as D- and L-isomers, because each molecule has at least one carbon atom with four different groups attached. Only a few of the many known monosaccharides are of major biological importance. All are D-sugars, and most are 5- and 6-carbon sugars (pentoses and hexoses). D-Glucose, D-fructose, D-ribose, and 2-deoxy-D-ribose are by far the most important sugars. D-Glucose

*Genetic engineering* refers to the manipulation of nucleic acids to change the characteristics of organisms (for example, to correct genetic flaws).

**Figure 24.11** ▲

**Active site on an enzyme** Here a yeast enzyme (represented by the ribbon model showing its polypeptide backbone) holds the thiamine molecule (vitamin B<sub>1</sub>, shown here as a space-filling model, in gray) at an active site in the enzyme.

is common blood sugar, an important energy source for cell function. D-Fructose is a common sugar in fruits and is involved in cell metabolism (the chemical processes occurring in the cell). D-Ribose and 2-deoxy-D-ribose are parts of nucleic acids, as we noted earlier, where we referred to them simply as ribose and deoxy-ribose. You could regard 2-deoxy-D-ribose as derived from D-ribose by replacing the hydroxyl group on carbon 2 by a hydrogen atom. (The numbering convention is shown below.)

Although one often draws the simple sugars as straight-chain molecules, they do not exist predominantly in that form. The chain curls up and the carbonyl group reacts with an alcohol group. With aldehydes, alcohols give *hemiacetals*, or compounds in which an —OH group, an —OR group, and an H atom are attached to the same carbon atom.

A ketone and an alcohol give a *hemiketal*, which is similar to a hemiacetal except that the H atom is replaced by an R" group.

The straight-chain form of D-glucose, whose formula we gave earlier, is a flexible molecule that can bend around to give a cyclic hemiacetal.

The straight-chain form, in the center, is shown bent around so that an —OH group and the —CHO group can react to give a cyclic hemiacetal. A new —OH group is obtained (on the right in each hemiacetal) and can point either down or up. Thus, there are two isomers of the hemiacetal—one labeled  $\alpha$  (—OH down) and the other labeled  $\beta$  (—OH up).

Although for simplicity we have drawn the six-membered rings of the hemiacetals as flat, they are in fact puckered, as shown in these more accurate three-dimensional formulas:

In these three-dimensional formulas, it is understood that there are carbon and hydrogen atoms at each of the corners in the ring, except where there is an oxygen atom.

The structures of the sugars we will need in this section are

These sugars have five-membered rings. Four of the ring atoms are planar, but either carbon atom 2 or carbon atom 3 (with attached H and OH) points upward or downward from the planar ring atoms.

## Nucleotides

**Nucleotides** are the building blocks of nucleic acids. There are two types: *ribonucleotides* and *deoxyribonucleotides*. The general structure of nucleotides consists of an organic base (described below) linked to carbon 1 of a pentose (5-carbon sugar), which is linked in turn at carbon 5 to a phosphate group. The only difference between the two types of nucleotides is in the sugar. Ribonucleotides contain  $\beta$ -D-ribose; deoxyribonucleotides contain 2-deoxy- $\beta$ -D-ribose. Both sugar groups have five-membered rings.

The carbon atoms of ribose are labeled with numbers 1', 2', . . . , 5'. (Numbers without primes are used for carbon atoms in the organic base.) Note that the phosphate group is shown in ionized form  $-\text{PO}_4^{2-}$ , as this form predominates near neutral pH in cells.

Five organic bases (amines) are most often found in nucleotides. The bases are *adenine*, *guanine*, *cytosine*, *uracil*, and *thymine*. They link to the sugars through the indicated nitrogen (in color) in each of the following structural formulas:

The base plus the sugar group (without the phosphate group) is called a *nucleoside*. Nucleosides are named from the bases. For example, the nucleoside composed of adenine with  $\beta$ -D-ribose is called adenosine. The nucleoside composed of adenine with 2-deoxy- $\beta$ -D-ribose is called deoxyadenosine. A nucleotide is named by adding monophosphate (or diphosphate or triphosphate) after the nucleoside name. A number with a prime indicates the position of the phosphate group on the ribose ring. Thus, adenosine-5'-monophosphate is a nucleotide composed of adenine,  $\beta$ -D-ribose, and a phosphate group at the 5' position of  $\beta$ -D-ribose.

### Polynucleotides and Their Conformations

A **polynucleotide** is a linear polymer of nucleotide units linked from the hydroxyl group at the 3' carbon of the pentose of one nucleotide to the phosphate group of the other nucleotide. For example,

Just as the unique sequence of amino acids in a protein determines the protein's nature, so the sequence of nucleotides determines the particular properties and functions of a polynucleotide. **Nucleic acids** are *polynucleotides folded or coiled into specific three-dimensional shapes*.

**Complementary bases** are *nucleotide bases that form strong hydrogen bonds with one another*. Adenine and thymine are complementary bases, as are adenine and uracil, and guanine and cytosine. Hydrogen bonding of complementary bases, called *base pairing*, is the key to nucleic acid structure and function (see Figure 24.12).

**Deoxyribonucleic acid (DNA)** is *the hereditary constituent of cells and consists of two polymer strands of deoxyribonucleotide units*. One of the strands consists of

**Figure 24.12** ▶

**Hydrogen-bonded complementary bases** Each base hydrogen-bonds strongly to only its complementary base. Adenine hydrogen-bonds to thymine or to uracil; guanine hydrogen-bonds to cytosine.

nucleotide bases that are complementary to those of the other strand. The two strands coil about each other in a double helix, with base pairing along the entire lengths of the strands (Figure 24.13). **Ribonucleic acid (RNA)** is a constituent of cells that is used to manufacture proteins from genetic information. It is a polymer of ribonucleotide units. Both DNA and RNA have nucleotides with the bases adenine, guanine, and cytosine. In addition, DNA contains thymine but not uracil, and RNA contains uracil but not thymine. It is often convenient in writing the bases in DNA and RNA sequences to use the abbreviations A = adenine, C = cytosine, G = guanine, T = thymine, and U = uracil.

### DNA and the Nature of the Genetic Code

Photomicrographs of dividing cells show structures, called chromosomes, as dense, thick rods (Figure 24.14). *Chromosomes* are cell structures that contain DNA and proteins; the DNA contains the genetic inheritance of the cell and organism. Before cell division, the cell synthesizes a new and identical set of chromosomes or, more particularly, a new and identical set of DNA molecules—the genetic information—to be transmitted to the new cell. Thus, the new cell will have all the necessary instructions for normal structure and function.

What is the nature of this genetic information? The genetic information is coded into the linear sequence of nucleotides in the DNA molecule. Each DNA molecule is composed of hundreds of genes. A **gene** is a sequence of nucleotides in a DNA molecule that codes for a given protein. The nucleotides in a gene are grouped in sets of three, or triplets. Each triplet codes for one amino acid in a protein.

New DNA must be synthesized during cell division, as we mentioned. This synthesis, or DNA replication, proceeds as follows. The two strands of DNA unravel at one end of the helix to form two single strands. As the two strands unravel, and with the aid of an enzyme called *polymerase*, complementary nucleotides are attached one after the other to these single strands to form two new double strands of DNA. At the completion of the process, two double-stranded DNA chains exist where previously there was one (Figure 24.15).

A similar laboratory technique, based on the *polymerase chain reaction (PCR)*, is used to amplify the quantity of DNA in a sample. In the PCR technique, a sample of DNA is heated with polymerase to separate the DNA into single strands. The polymerase then catalyzes the formation of new double-stranded DNA by adding complementary nucleotides to the original single strands. The process is continued, separating double-stranded DNA into single strands and forming new double-stranded DNA from these. Within hours, the original sample of DNA can be amplified a millionfold. Using PCR, researchers can diagnose diseases by identifying the DNA of infectious agents originally present in minute quantities in blood, food, and other samples. The PCR technique also makes it possible to replicate the DNA from Egyptian mummies and ancient bone samples.

Occasionally, an error is made during the synthesis of new DNA. Such a change in the genetic information, or *genetic error*, is called a *mutation*. One possible consequence could be the synthesis of a faulty or inactive protein. We know of various genetic diseases that result from a single error leading to the change of an amino acid in a protein sequence that has a profound effect on the protein's activity—and so on the life of the organism.

### RNA and the Transmission of the Genetic Code

RNA is used to translate the genetic information stored in DNA into protein structure. There are three classes of RNA: ribosomal RNA, messenger RNA, and transfer RNA.

**Ribosomes** are tiny cellular particles on which protein synthesis takes place. They are constructed of numerous proteins plus three or four RNA molecules. The RNA in a ribosome is called **ribosomal RNA**. Ribosomes provide a surface on which to organize the process of protein synthesis, and they also contain enzymes that catalyze the process.

**Figure 24.13** ▲

#### Double helix of the DNA molecule

The structure was first deduced by James Watson, an American scientist, and Francis Crick, a British scientist, in the early 1950s.

Ed Reschke/Getty Images

**Figure 24.14** ▲

#### Chromosomes in a dividing cell

The chromosomes appear as rods, stained purple. The cell synthesizes a new set of the original chromosomes and the two sets then migrate to opposite sides of the cell, in preparation for cell division.

**Figure 24.15** ▲

**DNA replication** The first stage of replication involves the unraveling of the two chains of the DNA double helix. As the chains begin to unravel, the exposed bases on each chain attract the complementary bases. The process is finished when there are two DNA double helices where there had been only one.

A **messenger RNA (mRNA)** molecule is a *relatively small RNA molecule that can diffuse about the cell and attach itself to a ribosome, where it serves as a pattern for protein biosynthesis*. The first step in protein biosynthesis, called *transcription*, is synthesis of a messenger RNA molecule that has a sequence of bases complementary to that of a portion of a DNA strand corresponding to a single protein (Figure 24.16).

A *sequence of three bases in a messenger RNA molecule that serves as the code for a particular amino acid* is called a **codon**. When the messenger RNA molecule attaches itself to a ribosome, its codons provide the sequence of amino acids in a protein that will be synthesized. *Translation* is the biosynthesis of protein using messenger RNA codons. Table 24.3, the complete messenger RNA code-word dictionary, shows the specific amino acids coded for by messenger RNA codons. There are 64 possible arrangements of the four RNA bases, so there are 64 codons. Three of the codons do not signify amino acids but signify the end of a message and thus are called *termination codons*. The remaining 61 codons signify particular amino acids. Because only 20 different amino acids exist in proteins, there are a number of instances in which 2, 3, 4, or even 6 codons translate to the same amino acid.

A **transfer RNA (tRNA)** molecule is a *small RNA molecule that binds to a particular amino acid and carries it to a ribosome*. At the ribosome, the tRNA molecule attaches itself through base pairing to an mRNA codon. The amino acid is then transferred to a growing protein chain. The process of protein biosynthesis stops when a termination codon is reached on the mRNA.

Figure 24.17 illustrates this process of biosynthesis. At the right, a tRNA molecule carrying an amino acid (labeled  $aa_8$ —tRNA<sub>8</sub>) is about to bind to the mRNA attached to the ribosome. Note that tRNA<sub>8</sub> has a sequence of three bases (AGU) complementary to the bases on the mRNA (UCA) to which it is about to bind. The codon UCA is the code for the amino acid serine (see Table 24.3), and this is the amino acid  $aa_8$  carried by tRNA<sub>8</sub>. On the ribosome, tRNA<sub>6</sub> is about to leave as its amino acid  $aa_6$  has been attached to the growing polypeptide chain. (Can you figure out what amino acid this is?) Its place will be taken by tRNA<sub>7</sub> as the ribosome moves right, enveloping tRNA<sub>8</sub> with its amino acid  $aa_8$ . Eventually the completed polypeptide chain will leave the ribosome as a newly synthesized protein molecule.

**Figure 24.16** ▲

**Formation of messenger RNA (transcription)** A portion of a DNA double helix corresponding to a single protein unravels, and complementary ribonucleotides line up, attracted by hydrogen bonding to one of the DNA chains. The ribonucleotides are then linked to form messenger RNA. After being released from the DNA, the messenger RNA migrates from the cell nucleus into the cytoplasm to a ribosome, where protein biosynthesis occurs.

Table 24.3 Genetic Code Dictionary\*

		Second letter				
		U	C	A	G	
First letter	U	UUU Phenylalanine UUC Phenylalanine UUA Leucine UUG Leucine	UCU Serine UCC Serine UCA Serine UCG Serine	UAU Tyrosine UAC Tyrosine UAA Stop codon UAG Stop codon	UGU Cysteine UGC Cysteine UGA Stop codon UGG Tryptophan	U C A G

\*The four nucleotide bases of RNA—U, C, A, and G—are arranged along the left side of the table and along the top. Combining any two of them and then adding a third (again, U, C, A, or G) gives one of the 64 three-nucleotide codons shown in capital letters in the table. Next to each codon appears the name of the amino acid it codes for during protein biosynthesis. In three cases, the phrase *Stop codon* appears because each of these codons serves as a signal to terminate protein biosynthesis.

Figure 24.17 ◀

**Synthesis of protein molecules (translation)** Messenger RNA (mRNA) provides the code needed to determine the sequence of amino acids to be added to the protein. A transfer RNA molecule (tRNA) is shown here bringing an amino acid ( $aa_8$ , amino acid 8) to the mRNA bound to a ribosome. The amino-acid-6 ( $aa_6$ ) end of the growing polypeptide chain will be transferred to  $aa_7$  as the tRNA with  $aa_8$  adds to the mRNA. After transfer of its amino acid, the tRNA molecule leaves the mRNA.

### CONCEPT CHECK 24.2

Write the RNA sequence complementary to the following DNA sequence:

**Figure 24.18** ▲

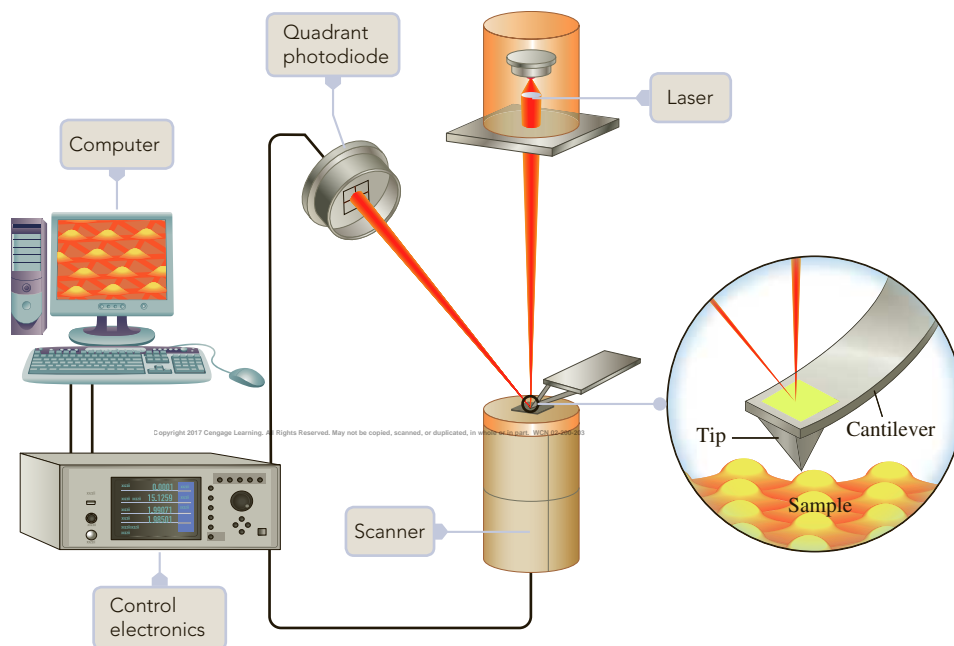

**Tobacco mosaic virus rods** The virus rods are covered with adsorbed protein molecules (bovine serum albumin). The protein molecules show up as bright bumps on the dark yellow color of the virus. A computer adds color to the image to create contrast.

agent that infects tobacco and many other crops. Each virus rod is covered by molecules of bovine serum albumin (from the blood serum of cows). Chemists obtained this image as part of a study of the interaction of the albumin protein molecule with the virus. The virus itself consists of a strand of RNA, containing the genetic material of the virus, surrounded by a protective protein coat.

The atomic force microscope (Figure 24.19) is a cousin of the scanning tunneling microscope, which we discussed in an essay at the end of Section 7.4. Both microscopes use a probe to scan a surface; but whereas the scanning tunneling microscope measures an electric current between the probe tip and the sample, the atomic force microscope measures the attractive van der Waals force between the probe tip and the sample. The advantage of the atomic force microscope is that it can be used with almost any surface, whereas a scanning tunneling microscope requires a conductive surface.

**Figure 24.19** ►

**Atomic force microscope** The sample moves by a scanner under a fixed probe. The probe consists of a silicon nitride tip attached to a cantilever, which can move up and down. A laser beam is reflected from the back of the cantilever to a photodiode divided into four segments (quadrant photodiode). As the cantilever bends up and down (or left and right) from surface forces acting on the probe tip, it deflects the laser beam to different quadrants of the photodiode. A computer coordinates the output from the photodiode with the sample position to create an image that appears on the computer screen.

## ✓ A Checklist for Review

### Summary of Facts and Concepts

*Polymers* are species of very high molecular weight consisting of many units (*monomers*). They are classified as *addition polymers* or *condensation polymers*, depending on the type of reaction used in forming them. Rubber is an addition polymer. Natural rubber is a *homopolymer* of isoprene units; the synthetic rubber SBR (styrene-butadiene rubber) is a *copolymer*. Nylon-6,6 is an example of a condensation polymer; it is produced by condensing hexamethylene diamine with adipic acid.

Certain polymers, such as *trans*-polyacetylene, are semiconductors. By doping them with substances such as iodine, their electrical conductivities can be greatly increased. One of the first applications of a conducting polymer was to produce a battery. These polymers have also been used to produce electronic devices, including transistors and LEDs.

Proteins are polymers of  $\alpha$ -*amino acids* linked by *peptide bonds*. The 20 common amino acids of protein have different *side chains*, which may be *polar* or *nonpolar*. The unique *primary structure* of a polypeptide (the amino-acid sequence) is responsible for spontaneous folding into a unique shape maintained by interactions

between side chains and disulfide bonds. This folding produces surface features responsible for the protein's function. An enzyme has an *active site* where catalysis takes place.

Nucleic acids are polymers of *nucleotides*. Nucleotides are base-sugar-phosphate compounds. Conformations of nucleic acids are the result of hydrogen bonding, called base pairing, between *complementary bases*. *DNA* is the genetic material of chromosomes. DNA consists of two complementary polynucleotides coiled into a *double helix*; each has all the information necessary to direct synthesis of a new complementary strand. The genetic code is the relationship between nucleotide sequence and protein amino-acid sequence. Sixty-four *codons* (three-nucleotide sequences) are the basis of the code. *Transcription* is the synthesis of a *messenger RNA* molecule, which represents a copy of the information in a DNA *gene*. The messenger RNA binds to a *ribosome*, where *translation* of the message into an amino-acid sequence occurs. *Transfer RNA* molecules attach to amino acids and bind to the messenger RNA by base pairing, bringing each amino acid in turn into the position specified by the codon sequence.

### Learning Objectives

#### 24.1 Synthesis of Organic Polymers

- Define *polymer* and *monomer*.
- Define *addition polymer*.
- Describe free-radical addition.
- Describe the nature of natural and synthetic rubber.
- Define *homopolymer* and *copolymer*.
- Define *condensation polymer*.
- Describe the synthesis of polyesters and polyamides.

### Important Terms

**polymer**  
**monomer**  
**addition polymer**  
**homopolymer**  
**copolymer**  
**condensation polymer**

#### 24.2 Electrically Conducting Polymers

- Describe the discovery of electrically conducting polymers.
- Explain how these polymers conduct electricity.

#### 24.3 Proteins

- Define *proteins* and *amino acids*.
- Define a *peptide (amide) bond*.
- Define a *peptide*.
- Define the *primary structure* of a protein.
- Describe the shapes of proteins.
- Define *fibrous protein* and *globular protein*.
- Define the *secondary* and *tertiary structures* of a protein.

**proteins**  
**amino acid**  
**peptide (amide) bonds**  
**polypeptide**  
**primary structure (of a protein)**  
**fibrous proteins**  
**secondary structure (of a protein)**  
**globular proteins**  
**tertiary structure (of a protein)**

## 24.4 Nucleic Acids

- Note the two types of nucleic acids.
- Describe the structure of the monosaccharides.
- Define *nucleotides* and *polynucleotides*.
- Define *nucleic acids*, *complementary bases*, *deoxyribonucleic acid (DNA)*, and *ribonucleic acid (RNA)*.
- Describe the nature of the genetic code.
- Describe how RNA translates the genetic code in DNA to protein structure.
- Define *ribosomes*, *ribosomal RNA*, *messenger RNA*, *codon*, and *transfer RNA*.

**nucleotides**  
**polynucleotide**  
**nucleic acids**  
**complementary bases**  
**deoxyribonucleic acid (DNA)**  
**ribonucleic acid (RNA)**  
**gene**  
**ribosomes**  
**ribosomal RNA**  
**messenger RNA**  
**codon**  
**transfer RNA**

## Questions and Problems

### Self-Assessment and Review Questions

**Key:** These questions test your understanding of the ideas you worked with in the chapter. These problems vary in difficulty and often can be used for the basis of discussion.

- 24.1** What is the difference between an addition polymer and a condensation polymer? Give an example of each, writing the equation for its formation.
- 24.2** Write the equation for the addition of one isoprene molecule to another.
- 24.3** Give the structural formula for a portion of the chain polymer obtained by the reaction of ethylene glycol,  $\text{CH}_2\text{OH}-\text{CH}_2\text{OH}$ , with adipic acid,  $\text{HOOC}-(\text{CH}_2)_4-\text{COOH}$ .
- 24.4** Show how the pi electrons in one resonance formula of polyacetylene would have to shift to obtain the other resonance formula.
- 24.5** Explain how the doping of polyacetylene increases its electrical conductivity.
- 24.6** Describe the primary structure of protein. What makes one protein different from another protein of the same size? What is the basis of the unique conformation of a protein?
- 24.7** Distinguish between secondary and tertiary structures of proteins.
- 24.8** What is an enzyme?
- 24.9** What is the difference in structure between D-ribose and 2-deoxy-D-ribose?
- 24.10** What are the structural forms of D-glucose present in the blood?
- 24.11** Name the complementary base pairs. Describe the DNA double helix.
- 24.12** How do ribonucleotides and deoxyribonucleotides differ in structure? Do they form polymers in the same way?
- 24.13** Explain the nature of the genetic code.
- 24.14** Define *codon* and *anticodon*. How do they interact?
- 24.15** Show mathematically why there are 64 possible triplet codons.
- 24.16** Outline how the genetic message in a gene is translated to produce a polypeptide. Include the roles of the gene, messenger RNA, ribosomes, and transfer RNA.
- 24.17** An amino acid must contain which of the following functional groups?
- |                            |                    |                            |                     |
|----------------------------|--------------------|----------------------------|---------------------|
| <input type="checkbox"/> a | carboxyl and nitro | <input type="checkbox"/> b | methyl and carboxyl |
| <input type="checkbox"/> c | alcohol and amido  | <input type="checkbox"/> d | amino and carboxyl  |
| <input type="checkbox"/> e | ketal and amino    |                            |                     |
- 24.18** An example of an addition polymer is
- |                            |           |                            |           |                            |        |
|----------------------------|-----------|----------------------------|-----------|----------------------------|--------|
| <input type="checkbox"/> a | polyester | <input type="checkbox"/> b | nylon-6,6 | <input type="checkbox"/> c | rubber |
| <input type="checkbox"/> d | Dacron    | <input type="checkbox"/> e | glucose   |                            |        |
- 24.19** The bonding responsible for linking the two strands that constitute DNA is
- |                            |                    |                            |                  |
|----------------------------|--------------------|----------------------------|------------------|
| <input type="checkbox"/> a | covalent bonding   | <input type="checkbox"/> b | ionic bonding    |
| <input type="checkbox"/> c | ion-dipole bonding | <input type="checkbox"/> d | hydrogen bonding |
| <input type="checkbox"/> e | phosphate linkages |                            |                  |
- 24.20** The complementary base of guanine is
- |                            |         |                            |         |                            |          |
|----------------------------|---------|----------------------------|---------|----------------------------|----------|
| <input type="checkbox"/> a | thymine | <input type="checkbox"/> b | guanine | <input type="checkbox"/> c | cytosine |
| <input type="checkbox"/> d | adenine | <input type="checkbox"/> e | uracil  |                            |          |

### Conceptual Problems

**Key:** These problems are designed to check your understanding of the concepts associated with some of the main topics presented in each chapter. A strong conceptual understanding of chemistry is the foundation for both applying chemical knowledge and solving chemical problems. These problems vary in level of difficulty and often can be used as a basis for group discussion.

**24.21** It is your job to manufacture polymers from a series of monomer units. These monomer units are called A, B, and C. In this problem you need to “build”

polymers by linking the monomer units. Represent the polymer linkages using dashes. For example,  $-\text{A}-\text{B}-\text{C}-$  represents a polymer unit made from linking monomer units A, B, and C.

- a Build two different homopolymers from your monomer units.
- b Build a copolymer from A and B.
- c Build a copolymer that is about 33% C and 66% A.
- 24.22** Use resonance formulas to explain why polyacetylene has delocalized molecular orbitals extending over the

length of the molecule, whereas the following molecule does not.

**24.23** Glutamic acid, a non-essential amino acid, is synthesized from a number of amino acids in the body. The structural formula of glutamic acid is

Write the fully ionized form of the molecule.

**24.24** Write the structural formulas of all possible tripeptides with the composition of two glycines and one serine. (See the structural formulas in Table 24.2.)

**24.25** What amino-acid sequence would result if the following messenger RNA sequence were translated from left to right?

**24.26** Give one of the nucleotide sequences that would translate to the peptide lys–pro–ala–phe–trp–glu–his–gly.

## Practice Problems

**Key:** These problems are for practice in applying problem-solving skills. They are divided by topic. The problems are arranged in matching pairs; the odd-numbered problem of each pair is listed first, and its answer is given in the back of the book.

### Synthetic Polymers

**24.27** Teflon is an addition polymer of 1,1,2,2-tetrafluoroethene. Write the equation for the formation of the polymer.

**24.28** Poly(vinyl chloride) (PVC) is an addition polymer of vinyl chloride,  $\text{CH}_2=\text{CHCl}$ . Write the equation for the formation of the polymer.

**24.29** Consider the following polymer:

From which two monomers is the polymer made?

**24.30** Consider the following polymer:

From which two monomers is the polymer made?

### Conducting Polymers

**24.31** Which of the following monomers might you expect would lead to a conducting polymer?

**24.32** Which of the following monomers might you expect to lead to a conducting polymer?

### Amino Acids and Primary Structure

**24.33** Valine has the structure

Draw the zwitterion that would exist at neutral pH.

**24.34** Valine has the structure

Draw the zwitterion that would exist at neutral pH.

**24.35** Write the structural formula of a dipeptide formed from the reaction of L-alanine and L-histidine. How many dipeptides are possible?

**24.36** Write the structural formulas of two tripeptides formed from the reaction of L-tryptophan, L-glutamic acid, and L-tyrosine. How many tripeptides are possible?

### Nucleotides and Polynucleotides

**24.37** If adenine, thymine, guanine, and cytosine were each analyzed separately in a sample of DNA, what molar ratios of A : T and G : C would you expect to find?

**24.38** If a sample of DNA isolated from a microorganism culture were analyzed and found to contain 3.5 mol of cytosine nucleotides and 4.5 mol of adenosine nucleotides, what would be the amounts of guanine and thymine nucleotides in the sample?

**24.39** Write a structural formula for the nucleotide adenosine-5'-monophosphate.

**24.40** Write a structural formula for the nucleotide deoxyadenosine-5'-monophosphate.

**24.41** How many hydrogen bonds link a guanine–cytosine base pair? an adenine–uracil base pair? Would you expect any difference in strength between guanine–cytosine bonding and adenine–uracil bonding? Explain.

**24.42** How many hydrogen bonds link an adenine–thymine base pair? Would there be any difference in strength between adenine–thymine bonding and adenine–uracil bonding? between adenine–thymine and cytosine–guanine bonding? Explain.

### DNA, RNA, and Protein Synthesis

**24.43** If a codon consists of two nucleotides, how many codons would be possible? Would this be a workable code for the purpose of protein synthesis?

**24.44** If a codon consists of four nucleotides, how many codons would be possible? Would this be workable as an amino-acid code?

**24.45** Nucleic acids can be denatured by heat, as proteins can. What bonds are broken when a DNA molecule is

denatured? Would DNA of greater percentage composition of guanine and cytosine denature more or less readily than DNA of greater percentage composition of adenine and thymine?

**24.46** Would RNA of a certain percentage composition of guanine and cytosine denature more or less readily than RNA with a lower percent of guanine and cytosine? Why?

**24.47** Consulting Table 24.3, write the amino-acid sequence resulting from left-to-right translation of the messenger RNA sequence

**24.48** Write the amino-acid sequence obtained from left-to-right translation of the messenger RNA sequence

See Table 24.3.

## General Problems

**Key:** These problems provide more practice but are not divided by topic. Each section ends with essay questions, each of which is color coded to refer to the *A Chemist Looks at Materials* (blue) or *A Chemist Looks at Life Science* (pink) chapter essay on which it is based. Odd-numbered problems and the even-numbered problems that follow are similar; answers to all odd-numbered problems except the essay questions are given in the back of the book.

**24.49** List the codons to which the following anticodons would form base pairs:

Anticodon: GAC UAC AAA CAA

Codon:

**24.50** List the anticodons to which the following codons would form base pairs:

Codon: UUG CAC ACU GAA

Anticodon:

**24.51** Give one of the nucleotide sequences that would translate to

leu-his-arg-ile-pro-his-thr-ser-phe-met

**24.52** Write one nucleotide sequence that would translate to

tyr-ile-pro-his-leu-his-thr-ser-phe-met

**24.53** Write the structural formula of the addition polymer made from *trans*-1,2-dichloroethene:

**24.54** Neoprene is an addition polymer of chloroprene:

Write the structural formula of neoprene.

**24.55** Kevlar<sup>®</sup> is a polymer fiber used to make bulletproof vests.

What are the structures of the monomer units in this polymer?

**24.56** Nylon-6 has the following structure:

What is the structure of the monomer unit in this polymer? Show the reaction corresponding to the formation of the polymer.

**24.57** Which of the following amino acids has a nonpolar side chain?

**24.58** Which of the following amino acids has a polar side chain?

**24.59** Draw the zwitterion structure for the amino acid serine.

**24.60** Draw the zwitterion structure for the amino acid leucine.

**24.61** Write the structural formula of one of the two dipeptides that could be formed from the amino acids in Problem 24.57.

**24.62** Write the structural formula of one of the two peptides that could be formed by the amino acids in Problem 24.58.

**24.63** A peptide contains six amino acids: L-arginine, L-proline, L-glutamic acid, L-glycine, L-asparagine, and L-glutamine. How many different peptides of this amino-acid composition are possible?

**24.64** Using abbreviations for the amino acids, give three possible sequences of the peptide described in Problem 24.63.

**24.65** Name each of the three major constituents of the nucleotide adenosine-5'-monophosphate.

**24.66** Write the structural formula of deoxyguanosine-5'-monophosphate.

**24.67** Wallace Carothers is credited with establishing the science of synthetic polymers. Describe his basic idea that is used in the synthesis of polymers such as nylon and polyesters.

**24.68** Prior to Carothers's work, the structures of materials such as rubber, silk, and wool were thought by some to be aggregates of small molecules held together by unknown forces. How did Carothers's work help to elucidate the actual structures?

**24.69** Describe the basic principle involved in the atomic force microscope.

**24.70** What is the major advantage of the atomic force microscope over the similar scanning tunneling microscope?

## Strategy Problems

**Key:** As noted earlier, all of the practice and general problems are matched pairs. This section is a selection of problems that are not in matched-pair format. These challenging problems require that you employ many of the concepts and strategies that were developed in the chapter. In some cases, you will have to integrate several concepts and operational skills in order to solve the problem successfully.

**24.71** Polyesters are made by condensing dicarboxylic acids with glycols. A 1.273-g sample of a dicarboxylic acid was titrated with 0.2183 M NaOH. The sample was completely neutralized with 98.6 mL of the NaOH solution. Draw a possible structural formula for the dicarboxylic acid. Show the condensation reaction of this acid with ethylene glycol to produce the polyester.

**24.72** Consider the condensation of the diamine  $\text{H}_2\text{N}(\text{CH}_2)_n\text{NH}_2$  with sebacic acid,  $(\text{HOOC})(\text{CH}_2)_8(\text{COOH})$ , to obtain the polyamide. The polyamide has the following composition: 66.1% C, 10.3% H, 11.0% N, and 12.6% O. What is the value of  $n$ ?

**24.73** A 18.0-g sample of rubber (poly-*cis*-isoprene) reacts with bromine,  $\text{Br}_2$ , to produce the polymer in which bromine adds to each of the double bonds. Estimate the quantity of heat that evolves in this process.

**24.74** Aspartame, a low-calorie sweetener, is the methyl ester of a dipeptide. Its structure is

**a** Suppose aspartame is hydrolyzed (reacted with water). Give the names of the amino acids obtained from this hydrolysis.

**b** Draw the structure of another dipeptide that could be prepared from these amino acids.

**c** How many tripeptides could you make from the amino acids valine and alanine?

**24.75** The genetic code uses four bases taken in groups of three for each code.

**a** How many of these base groups are possible?

**b** Is this enough to establish a code for each of the 20 amino acids found in proteins?

**c** Imagine a genetic code that uses only two bases but uses groups of four of these bases for the genetic code. How many different groups of this type are possible?

**d** Is this enough to establish a code for each of the 20 amino acids found in proteins?

**e** Devise a hypothetical code of this type for the 20 amino acids in proteins. Then, using this code, write the base sequence for the tripeptide leu-ala-val.

**24.76** Hemoglobin is the protein in red blood cells that carries oxygen. This protein is composed of two parts: globin and heme, the part that contains all of the iron of hemoglobin. Heme has the following composition: 66.24% C, 5.23% H, 9.06% Fe, 9.09% N, and 10.38% O. Assuming one Fe atom per heme, obtain its molecular weight. The molecular weight of hemoglobin is approximately 64,500 amu. The hemoglobin molecule contains four globin units and four heme units. What is the approximate molecular weight of globin?

**24.77** A 1.500-g sample of a mixture of ribose and 2-deoxyribose was dissolved in 100.0 g of water. If the freezing point of the solution was  $-0.0556^\circ\text{C}$ , what is the percentage (by mass) of ribose in the mixture?

**24.78** Consider the zwitterion of the amino acid alanine, which is the predominant form of the acid at neutral pH. Draw its structural formula. Imagine that the pH of a solution of alanine is gradually lowered until the zwitterion picks up a proton. Draw the structural formula of the resulting ion. Write the chemical equation for this addition of a proton. Note that the equilibrium constant for the opposite reaction is  $K_a$ . The  $\text{p}K_a$  value for this is 2.3. Use the Henderson-Hasselbalch equation to obtain the ratio of the different ionic forms of alanine in the solution at a pH of 4.0. Which form predominates at this pH?

**24.79** A polymer is hydrolyzed to give an acidic substance and a compound that was found to have properties of an

alcohol. When this compound was oxidized, it produced an acid whose molecular weight was found to be 90.0 amu. A 0.145-g sample of this acid is completely neutralized with 30.5 mL of 0.1056 M NaOH to give a salt. The acid produced a white precipitate with calcium chloride. What was the precipitate that formed? Explain what is happening at each step.

**24.80** Natural rubber is an addition polymer of isoprene. Gutta percha is a similar rubber-like material, although its properties are rather different. (It is a hard material at room temperature but softens when heated.) Its structure

has the *trans* form of polyisoprene instead of the *cis* form present in natural rubber.

- a Draw the structure of gutta percha.
- b If a sample of gutta percha has an average molecular weight of 250,000 amu, what is the average number of isoprene units in the polymer?
- c When you stretch a rubber band, it evolves heat. If the stretched rubber band is then spontaneously allowed to contract to its equilibrium shape, it cools. Does the entropy of rubber increase or decrease when it is stretched?

# Appendixes

## Appendix A Mathematical Skills

Only a few basic mathematical skills are required for the study of general chemistry. But to concentrate your attention on the concepts of chemistry, you will find it necessary to have a firm grasp of these basic mathematical skills. In this appendix, we will review scientific (or exponential) notation, logarithms, simple algebraic operations, the solution of quadratic equations, and the plotting of straight-line graphs.

### A.1 Scientific (Exponential) Notation

In chemistry, you frequently encounter very large and very small numbers. For example, the number of molecules in a liter of air at 20°C and normal barometric pressure is 25,000,000,000,000,000,000, and the distance between two hydrogen atoms in a hydrogen molecule is 0.000,000,000,074 meter. In these forms, such numbers are inconvenient to write and difficult to read. For this reason, you normally express them in scientific, or exponential, notation. Scientific calculators also use this notation.

In scientific notation, a number is written in the form  $A \times 10^n$ .  $A$  is a number greater than or equal to 1 and less than 10, and the exponent  $n$  (the  $n$ th power of 10) is a positive or negative integer. For example, 4853 is written in scientific notation as  $4.853 \times 10^3$ , which is 4.853 multiplied by three factors of 10:

$$4.853 \times 10^3 = 4.853 \times 10 \times 10 \times 10 = 4853$$

The number 0.0568 is written in scientific notation as  $5.68 \times 10^{-2}$ , which is 5.68 divided by two factors of 10:

$$5.68 \times 10^{-2} = \frac{5.68}{10 \times 10} = 0.0568$$

Any number can be conveniently transformed to scientific notation by moving the decimal point to obtain a number,  $A$ , greater than or equal to 1 and less than 10. If the decimal point is moved to the left, you multiply  $A$  by  $10^n$ , where  $n$  equals the number of places moved. If the decimal point is moved to the right, you multiply  $A$  by  $10^{-n}$ . Consider the number 0.00731. You must move the decimal point to the right three places. Therefore, 0.00731 equals  $7.31 \times 10^{-3}$ . To transform a number written in scientific notation to the usual form, the process is reversed. If the exponent is positive, the decimal point is shifted right. If the exponent is negative, the decimal point is shifted left.

#### Example 1 Expressing Numbers in Scientific Notation

	Express the following numbers in scientific notation:	a. 843.4 b. 0.00421 c. 1.54
	<b>Solution</b> Shift the decimal point to get a number between 1 and 10; count the number of positions shifted.	a. <del>843.</del> 4 = $8.434 \times 10^2$ b. 0. <del>004</del> 21 = $4.21 \times 10^{-3}$ c. <b>leave as is or write</b> $1.54 \times 10^0$
	<b>Exercise 1</b> Express the following numbers in scientific notation:	a. 4.38 b. 4380 c. 0.000483

Example 2 Converting Numbers in Scientific Notation to Usual Form		
	Convert the following numbers in scientific notation to usual form:	a. $6.39 \times 10^{-4}$ b. $3.275 \times 10^2$
	<b>Solution</b> a. $0.000639$ , $3.9 \times 10^{-4} = 0.000639$ b. $327.5$ , $3.275 \times 10^2 = 327.5$	
	<b>Exercise 2</b> Convert the following numbers in scientific notation to usual form:	a. $7.025 \times 10^3$ b. $8.97 \times 10^{-4}$

### Addition and Subtraction

Before adding or subtracting two numbers written in scientific notation, it is necessary to express both to the same power of 10. After adding or subtracting, it may be necessary to shift the decimal point to express the result in scientific notation.

Example 3 Adding and Subtracting in Scientific Notation	
	Carry out the following arithmetic; give the result in scientific notation. $(9.42 \times 10^{-2}) + (7.6 \times 10^{-3})$
	<b>Solution</b> You can shift the decimal point in either number to obtain both to the same power of 10. For example, to get both numbers to $10^{-2}$ , you shift the decimal point one place to the left and add 1 to the exponent in the expression $7.6 \times 10^{-3}$ . $7.6 \times 10^{-3} = 0.76 \times 10^{-2}$ Now you can add the two numbers. $(9.42 \times 10^{-2}) + (0.76 \times 10^{-2}) = (9.42 + 0.76) \times 10^{-2} = 10.18 \times 10^{-2}$ Since 10.18 is not between 1 and 10, you shift the decimal point to express the final result in scientific notation. $10.18 \times 10^{-2} = 1.018 \times 10^{-1}$
	<b>Exercise 3</b> Add the following, and express the sum in scientific notation: $(3.142 \times 10^{-4}) + (2.8 \times 10^{-6})$

### Multiplication and Division

To multiply two numbers in scientific notation, you first multiply the two powers of 10 by adding their exponents. Then you multiply the remaining factors. Division is handled similarly. You first move any power of 10 in the denominator to the numerator, changing the sign of the exponent. After multiplying the two powers of 10 by adding their exponents, you carry out the indicated division.

Example 4 Multiplying and Dividing in Scientific Notation	
	Do the following arithmetic, and express the answers in scientific notation. a. $(6.3 \times 10^2) \times (2.4 \times 10^5)$ b. $\frac{6.4 \times 10^2}{2.0 \times 10^5}$
	<b>Solution</b> a. $(6.3 \times 10^2) \times (2.4 \times 10^5) = (6.3 \times 2.4) \times 10^7 = 15.12 \times 10^7 = 1.512 \times 10^8$ b. $\frac{6.4 \times 10^2}{2.0 \times 10^5} = \frac{6.4}{2.0} \times 10^2 \times 10^{-5} = \frac{6.4}{2.0} \times 10^{-3} = 3.2 \times 10^{-3}$

(continued)

**Example 4** (continued)

**Exercise 4** Perform the following operations, expressing the answers in scientific notation:

- a.  $(5.4 \times 10^{-7}) \times (1.8 \times 10^8)$   
 b.  $\frac{5.4 \times 10^{-7}}{6.0 \times 10^{-5}}$

**Powers and Roots**

A number  $A \times 10^n$  raised to a power  $p$  is evaluated by raising  $A$  to the power  $p$  and multiplying the exponent in the power of 10 by  $p$ :

$$(A \times 10^n)^p = A^p \times 10^{n \times p}$$

You extract the  $r$ th root of a number  $A \times 10^n$  by first moving the decimal point in  $A$  so that the exponent in the power of 10 is exactly divisible by  $r$ . Suppose this has been done, so that  $n$  in the number  $A \times 10^n$  is exactly divisible by  $r$ . Then

$$\sqrt[r]{A \times 10^n} = \sqrt[r]{A} \times 10^{n/r}$$

**Example 5 Finding Powers and Roots in Scientific Notation**

Evaluate the following expressions:

- a.  $(5.29 \times 10^2)^3$   
 b.  $\sqrt{2.31 \times 10^7}$

**Solution** a.  $(5.29 \times 10^2)^3 = (5.29)^3 \times 10^6 = 148 \times 10^6 = \mathbf{1.48 \times 10^8}$   
 b.  $\sqrt{2.31 \times 10^7} = \sqrt{23.1 \times 10^6} = \sqrt{23.1} \times 10^{6/2} = \mathbf{4.81 \times 10^3}$

**Exercise 5** Obtain the values of the following, and express them in scientific notation:

- a.  $(3.56 \times 10^3)^4$   
 b.  $\sqrt[3]{4.81 \times 10^2}$

**Electronic Calculators**

Scientific calculators will perform all of the arithmetic operations we have just described (as well as those discussed in the next section). On most calculators, the basic operations of addition, subtraction, multiplication, and division are similar and straightforward. However, more variation exists in raising a number to a power and extracting a root. If you have the calculator instructions, by all means read them. Otherwise, the following information may help.

Squares and square roots are usually obtained with special keys, perhaps labeled  $x^2$  and  $\sqrt{x}$ . Thus, to obtain  $(5.15)^2$ , you enter 5.15 and press  $x^2$ . To obtain  $\sqrt{5.15}$ , you enter 5.15 and press  $\sqrt{x}$  (or perhaps INV, for inverse, and  $x^2$ ). Other powers and roots require a  $y^x$  (or  $a^x$ ) key. The answer to Example 5(a), which is  $(5.29 \times 10^2)^3$ , would be obtained by a sequence of steps such as the following: enter  $5.29 \times 10^2$ , press the  $y^x$  key, enter 3, and press the = key.

The same sequence can be used to extract a root. Suppose you want  $\sqrt[5]{2.18 \times 10^6}$ . This is equivalent to  $(2.18 \times 10^6)^{1/5}$  or  $(2.18 \times 10^6)^{0.2}$ . If the calculator has a  $1/x$  key, the sequence would be as follows: enter  $2.18 \times 10^6$ , press the  $y^x$  key, enter 5, press the  $1/x$  key, then press the = key. Some calculators have a  $\sqrt[x]{y}$  key, so this can be used to extract the  $x$ th root of  $y$ , using a sequence of steps similar to that for  $y^x$ .

**A.2 Logarithms**

The *logarithm* to the base  $a$  of a number  $x$ , denoted  $\log_a x$ , is the exponent of the constant  $a$  needed to equal the number  $x$ . For example, suppose  $a$  is 10, and you would like the logarithm of 1000; that is, you would like the value of  $\log_{10} 1000$ . This is the exponent,  $y$ , of 10 such that  $10^y$  equals 1000. The value of  $y$  here is 3. Thus,  $\log_{10} 1000 = 3$ .

*Common logarithms* are logarithms in which the base is 10. The common logarithm of a number  $x$  is often denoted simply as  $\log x$ . It is easy to see how to obtain the common logarithms of 10, 100, 1000, and so forth. But logarithms are defined for all positive numbers, not just the powers of 10. In general, the exponents, or values, of the logarithm will be decimal numbers. To understand the meaning of a decimal exponent, consider  $10^{0.400}$ . This is equivalent to  $10^{400/1000} = 10^{2/5} = \sqrt[5]{10^2} = 2.51$ . Therefore,  $\log 2.51 = 0.400$ . Any decimal exponent is essentially a fraction,  $p/r$ , so by evaluating the expressions  $10^{p/r} = \sqrt[r]{10^p}$  one could construct a table of logarithms. In practice, power series or other methods are used.

The following are fundamental properties of all logarithms:

$$\log_a 1 = 0 \quad (1)$$

$$\log_a(A \times B) = \log_a A + \log_a B \quad (2)$$

$$\log_a \frac{A}{B} = \log_a A - \log_a B \quad (3)$$

$$\log_a A^p = p \log_a A \quad (4)$$

$$\log_a \sqrt[r]{A} = \frac{1}{r} \log_a A \quad (5)$$

These properties are very useful in working with logarithms.

Electronic calculators that evaluate logarithms are now available for about \$10 or so. Their simplicity of operation makes them well worth the price. To obtain the logarithm of a number, you enter the number and press the LOG key.

**Exercise 6** Find the values of a.  $\log 0.00582$ ; b.  $\log 689$ .

### Antilogarithm

The antilogarithm (abbreviated antilog) is the inverse of the common logarithm. Antilog  $x$  is simply  $10^x$ . If your electronic calculator has a  $10^x$  key, you obtain the antilogarithm of a number by entering the number and pressing the  $10^x$  key. (It may be necessary to press an inverse key before pressing a  $10^x$ /LOG key.) If your calculator has a  $y^x$  (or  $a^x$ ) key, you enter 10, press  $y^x$ , enter  $x$ , then press the = key.

**Exercise 7** Evaluate a. antilog 5.728; b. antilog  $(-5.728)$ .

### Natural Logarithms and Natural Antilogarithms

The mathematical constant  $e = 2.71828$ , like  $\pi$ , occurs in many scientific and engineering problems. It is frequently seen in the natural exponential function  $y = e^x$ . The inverse function is called the *natural logarithm*,  $x = \ln y$ , where  $\ln y$  is simplified notation for  $\log_e y$ .

Finding the natural logarithm with a calculator is analogous to finding the common logarithm, only in this case you enter the number and press the LN key. For example, you may obtain the natural logarithm of 6.2 by entering 6.2 and pressing the LN key ( $\ln 6.2 = 1.82$ ). The natural antilogarithm of a number is the constant  $e$  raised to a power equal to the number. Therefore, the expression for the natural antilogarithm of 1.34 is written as

$$\text{natural antilog } 1.34 = e^{1.34}$$

In order to evaluate the expression  $e^{1.34}$  on your calculator, you can use the  $e^x$  key, or you may have to use the INV key in combination with the LN key ( $e^{1.34} = 3.8$ ).

There are instances where you may want to relate the natural logarithm to the common logarithm; the expression is

$$\ln x = 2.303 \log x$$

**Exercise 8** Evaluate a.  $\ln 9.93$ ; b.  $e^{1.10}$ .

### A.3 Algebraic Operations and Graphing

Often you are given an algebraic formula that you need to rearrange to solve for a particular quantity. As an example, suppose you would like to solve the following equation for  $V$ :

$$PV = nRT$$

You can eliminate  $P$  from the left-hand side by dividing by  $P$ . But to maintain the equality, you must perform the same operation on both sides of the equation:

$$\frac{PV}{P} = \frac{nRT}{P}$$

or

$$V = \frac{nRT}{P}$$

#### Quadratic Formula

A quadratic equation is one involving only powers of  $x$  in which the highest power is 2. The general form of the equation can be written

$$ax^2 + bx + c = 0$$

where  $a$ ,  $b$ , and  $c$  are constants. For given values of these constants, only certain values of  $x$  are possible. (In general, there will be two values.) These values of  $x$  are said to be the solutions of the equation.

These solutions are given by the *quadratic formula*:

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

In this formula, the symbol  $\pm$  means that there are two possible values of  $x$ —one obtained by taking the positive sign, the other by taking the negative sign.

#### Example 6 Obtaining the Solutions of a Quadratic Equation

Obtain the solutions of the following quadratic equation:

$$2.00x^2 - 1.72x - 2.86 = 0$$

**Solution** Using the quadratic formula, you substitute  $a = 2.00$ ,  $b = -1.72$ , and  $c = -2.86$ . You get

$$x = \frac{1.72 \pm \sqrt{(-1.72)^2 - 4 \times 2.00 \times (-2.86)}}{2 \times 2.00} = \frac{1.72 \pm 5.08}{4.00} = -0.840 \text{ and } +1.70$$

Mathematically there are two solutions, but in any real problem one solution may not be allowed. For example, if the solution is some physical quantity that can have only positive values, a negative solution must be rejected.

**Exercise 9** Find the positive solution (or solutions) to the following equation:

$$1.80x^2 + 0.850x - 9.50 = 0$$

### The Straight-Line Graph

A graph is a visual means of representing a mathematical relationship or physical data. Consider the following data table, in which values of  $y$  from some experiment are given for four values of  $x$ .

$x$	$y$
1	-1
2	1
3	3
4	5

By plotting these  $x, y$  points on a graph (Figure A.1), you see that they fall on a straight line. This suggests (but does not prove) that other points from this type of experiment might fall on the same line. It would be useful to have the mathematical equation for this line.

The general equation form of a straight line is

$$y = mx + b$$

The constant  $m$  is called the *slope* of the straight line. It is obtained by dividing the vertical distance between any two points on the line by the horizontal distance. If the two points are  $(x_1, y_1)$  and  $(x_2, y_2)$ , the slope is given by the following formula:

$$\text{Slope} = \frac{y_2 - y_1}{x_2 - x_1}$$

Suppose you choose the points (2, 1) and (4, 5) from the data. Then

$$\text{Slope} = \frac{5 - 1}{4 - 2} = 2$$

For the straight line in Figure A.1,  $m = 2$ .

The constant  $b$  is called the *intercept*. It is the value of  $y$  at  $x = 0$ . From Figure A.1, you see that the intercept is  $-3$ . Therefore,  $b = -3$ . Hence, the equation of the straight line is

$$y = 2x - 3$$

Figure A.1 ►

A straight-line plot of some data

## Appendix B Vapor Pressure of Water at Various Temperatures

Temperature (°C)	Pressure (mmHg)	Temperature (°C)	Pressure (mmHg)
0	4.6	27	26.7
5	6.5	28	28.3
10	9.2	29	30.0

Configurations in this table are taken from the “Periodic Table: Atomic Properties of the Elements” given in [www.physics.nist.gov/data](http://www.physics.nist.gov/data), except those elements whose configurations are in parentheses; they were obtained on the basis of their assumed positions in the periodic table.

## Appendix E Acid-Ionization Constants at 25°C

Substance	Formula	K <sub>a</sub>
Acetic acid (Ethanoic acid)	HC <sub>2</sub> H <sub>3</sub> O <sub>2</sub>	1.7 × 10 <sup>-5</sup>
Arsenic acid*	H <sub>3</sub> AsO <sub>4</sub>	6.5 × 10 <sup>-3</sup>
	H <sub>2</sub> AsO <sub>4</sub> <sup>-</sup>	1.2 × 10 <sup>-7</sup>
	HAsO <sub>4</sub> <sup>2-</sup>	3.2 × 10 <sup>-12</sup>
Ascorbic acid*	H <sub>2</sub> C <sub>6</sub> H <sub>6</sub> O <sub>6</sub>	6.8 × 10 <sup>-5</sup>
	HC <sub>6</sub> H <sub>6</sub> O <sub>6</sub> <sup>-</sup>	2.8 × 10 <sup>-12</sup>
Benzoic acid	HC <sub>7</sub> H <sub>5</sub> O <sub>2</sub>	6.3 × 10 <sup>-5</sup>
Boric acid	H <sub>3</sub> BO <sub>3</sub>	5.9 × 10 <sup>-10</sup>
Carbonic acid*	H <sub>2</sub> CO <sub>3</sub>	4.3 × 10 <sup>-7</sup>
	HCO <sub>3</sub> <sup>-</sup>	4.8 × 10 <sup>-11</sup>
Chromic acid*	H <sub>2</sub> CrO <sub>4</sub>	1.5 × 10 <sup>-1</sup>
	HCrO <sub>4</sub> <sup>-</sup>	3.2 × 10 <sup>-7</sup>
Cyanic acid	HOCN	3.5 × 10 <sup>-4</sup>
Formic acid	HCHO <sub>2</sub>	1.7 × 10 <sup>-4</sup>
Hydrocyanic acid	HCN	4.9 × 10 <sup>-10</sup>
Hydrofluoric acid	HF	6.8 × 10 <sup>-4</sup>
Hydrogen peroxide	H <sub>2</sub> O <sub>2</sub>	1.8 × 10 <sup>-12</sup>

(continued)

(continued)

Substance	Formula	$K_a$
Hydrogen sulfate ion	$\text{HSO}_4^-$	$1.1 \times 10^{-2}$
Hydrogen sulfide*	$\text{H}_2\text{S}$	$8.9 \times 10^{-8}$
	$\text{HS}^-$	$1.2 \times 10^{-13}$
Hypochlorous acid	$\text{HClO}$	$3.5 \times 10^{-8}$
Lactic acid	$\text{HC}_3\text{H}_5\text{O}_3$	$1.3 \times 10^{-4}$
Nitrous acid	$\text{HNO}_2$	$4.5 \times 10^{-4}$
Oxalic acid*	$\text{H}_2\text{C}_2\text{O}_4$	$5.6 \times 10^{-2}$
	$\text{HC}_2\text{O}_4^-$	$5.1 \times 10^{-5}$
Phenol	$\text{C}_6\text{H}_5\text{OH}$	$1.1 \times 10^{-10}$
Phosphoric acid*	$\text{H}_3\text{PO}_4$	$6.9 \times 10^{-3}$
	$\text{H}_2\text{PO}_4^-$	$6.2 \times 10^{-8}$
	$\text{HPO}_4^{2-}$	$4.8 \times 10^{-13}$
Phosphorous acid*	$\text{H}_2\text{PHO}_3$	$1.6 \times 10^{-2}$
	$\text{HPO}_3^-$	$7 \times 10^{-7}$
Propionic acid	$\text{HC}_3\text{H}_5\text{O}_2$	$1.3 \times 10^{-5}$
Pyruvic acid	$\text{HC}_3\text{H}_3\text{O}_3$	$1.4 \times 10^{-4}$
Sulfurous acid*	$\text{H}_2\text{SO}_3$	$1.3 \times 10^{-2}$
	$\text{HSO}_3^-$	$6.3 \times 10^{-8}$

\*The ionization constants for polyprotic acids are for successive ionizations. For example, for  $\text{H}_3\text{PO}_4$ , the equilibrium is  $\text{H}_3\text{PO}_4 \rightleftharpoons \text{H}^+ + \text{H}_2\text{PO}_4^-$ . For  $\text{H}_2\text{PO}_4^-$ , the equilibrium is  $\text{H}_2\text{PO}_4^- \rightleftharpoons \text{H}^+ + \text{HPO}_4^{2-}$ .

## Appendix F Base-Ionization Constants at 25°C

Substance	Formula	$K_b$
Ammonia	$\text{NH}_3$	$1.8 \times 10^{-5}$
Aniline	$\text{C}_6\text{H}_5\text{NH}_2$	$4.2 \times 10^{-10}$
Dimethylamine	$(\text{CH}_3)_2\text{NH}$	$5.1 \times 10^{-4}$
Ethylamine	$\text{C}_2\text{H}_5\text{NH}_2$	$4.7 \times 10^{-4}$
Ethylenediamine	$\text{NH}_2\text{CH}_2\text{CH}_2\text{NH}_2$	$5.2 \times 10^{-4}$
Hydrazine	$\text{N}_2\text{H}_4$	$1.7 \times 10^{-6}$
Hydroxylamine	$\text{NH}_2\text{OH}$	$1.1 \times 10^{-8}$
Methylamine	$\text{CH}_3\text{NH}_2$	$4.4 \times 10^{-4}$
Pyridine	$\text{C}_5\text{H}_5\text{N}$	$1.4 \times 10^{-9}$
Trimethylamine	$(\text{CH}_3)_3\text{N}$	$6.5 \times 10^{-5}$
Urea	$\text{NH}_2\text{CONH}_2$	$1.5 \times 10^{-14}$

## Appendix G Solubility Product Constants at 25°C

Substance	Formula	$K_{sp}$
Aluminum hydroxide	$\text{Al}(\text{OH})_3$	$4.6 \times 10^{-33}$
Barium chromate	$\text{BaCrO}_4$	$1.2 \times 10^{-10}$
Barium fluoride	$\text{BaF}_2$	$1.0 \times 10^{-6}$
Barium sulfate	$\text{BaSO}_4$	$1.1 \times 10^{-10}$
Cadmium oxalate	$\text{CdC}_2\text{O}_4$	$1.5 \times 10^{-8}$
Cadmium sulfide	$\text{CdS}$	$8 \times 10^{-27}$
Calcium carbonate	$\text{CaCO}_3$	$3.8 \times 10^{-9}$
Calcium fluoride	$\text{CaF}_2$	$3.4 \times 10^{-11}$
Calcium oxalate	$\text{CaC}_2\text{O}_4$	$2.3 \times 10^{-9}$
Calcium phosphate	$\text{Ca}_3(\text{PO}_4)_2$	$1 \times 10^{-26}$
Calcium sulfate	$\text{CaSO}_4$	$2.4 \times 10^{-5}$
Cobalt(II) sulfide	$\text{CoS}$	$4 \times 10^{-21}$
Copper(II) hydroxide	$\text{Cu}(\text{OH})_2$	$2.6 \times 10^{-19}$
Copper(II) sulfide	$\text{CuS}$	$6 \times 10^{-36}$
Iron(II) hydroxide	$\text{Fe}(\text{OH})_2$	$8 \times 10^{-16}$
Iron(II) sulfide	$\text{FeS}$	$6 \times 10^{-18}$
Iron(III) hydroxide	$\text{Fe}(\text{OH})_3$	$2.5 \times 10^{-39}$
Lead(II) arsenate	$\text{Pb}_3(\text{AsO}_4)_2$	$4 \times 10^{-36}$
Lead(II) chloride	$\text{PbCl}_2$	$1.6 \times 10^{-5}$
Lead(II) chromate	$\text{PbCrO}_4$	$1.8 \times 10^{-14}$
Lead(II) iodide	$\text{PbI}_2$	$6.5 \times 10^{-9}$
Lead(II) sulfate	$\text{PbSO}_4$	$1.7 \times 10^{-8}$
Lead(II) sulfide	$\text{PbS}$	$2.5 \times 10^{-27}$
Magnesium arsenate	$\text{Mg}_3(\text{AsO}_4)_2$	$2 \times 10^{-20}$
Magnesium carbonate	$\text{MgCO}_3$	$1.0 \times 10^{-5}$
Magnesium hydroxide	$\text{Mg}(\text{OH})_2$	$1.8 \times 10^{-11}$
Magnesium oxalate	$\text{MgC}_2\text{O}_4$	$8.5 \times 10^{-5}$
Manganese(II) sulfide	$\text{MnS}$	$2.5 \times 10^{-10}$
Mercury(I) chloride	$\text{Hg}_2\text{Cl}_2$	$1.3 \times 10^{-18}$
Mercury(II) sulfide	$\text{HgS}$	$1.6 \times 10^{-52}$
Nickel(II) hydroxide	$\text{Ni}(\text{OH})_2$	$2.0 \times 10^{-15}$
Nickel(II) sulfide	$\text{NiS}$	$3 \times 10^{-19}$
Silver acetate	$\text{AgC}_2\text{H}_3\text{O}_2$	$2.0 \times 10^{-3}$
Silver bromide	$\text{AgBr}$	$5.0 \times 10^{-13}$
Silver chloride	$\text{AgCl}$	$1.8 \times 10^{-10}$
Silver chromate	$\text{Ag}_2\text{CrO}_4$	$1.1 \times 10^{-12}$

CaCO<sub>3</sub>(s) + 2H<sup>+</sup>(aq) → Ca<sup>2+</sup>(aq) + CO<sub>2</sub>(g) + H<sub>2</sub>O(l) **4.8** **a** K: +1, Cr: +6, O: -2 **b** Mn: +7, O: -2 **4.9** Ca + Cl<sub>2</sub> → Ca<sup>2+</sup> + 2Cl<sup>-</sup> **4.10** 0.0464 M NaCl **4.11** 10.1 mL **4.12** 0.0075 mol NaCl; 0.44 g NaCl **4.13** 12 mL **4.14** 34.19% **4.15** 48.4 mL NiSO<sub>4</sub> **4.16** 5.07%

## CHAPTER 5

**5.1** 0.56 atm, 4.3 × 10<sup>2</sup> mmHg **5.2** 24.1 L **5.3** 4.47 dm<sup>3</sup> **5.4** 5.54 dm<sup>3</sup> **5.5** Use PV = nRT. Solve for n: n = PV/RT = P(V/RT). Everything within parentheses is constant; therefore, n = constant × P (or ∝ P). **5.6** 46.0 atm **5.7** density of He = 0.164 g/L; difference in mass between 1 L of air and 1 L of He = 1.024 g **5.8** 64.1 amu **5.9** 2.00 L **5.10** P<sub>O<sub>2</sub></sub> = 0.0769 atm; P<sub>CO<sub>2</sub></sub> = 0.0310 atm; P = 0.1080 atm; X<sub>O<sub>2</sub></sub> = 0.712 **5.11** 0.01591 mol O<sub>2</sub>; V = 0.406 L **5.12** 219 m/s **5.13** T = 52.4 K, 728 K **5.14** 9.96 s **5.15** 44.0 amu **5.16** P<sub>vdW</sub> = 0.992 atm; P<sub>ideal</sub> = 1.000 atm (larger)

## CHAPTER 6

**6.1** 1.1 × 10<sup>-17</sup> J, 2.7 × 10<sup>-18</sup> cal **6.2** 3.89 J **6.3** exothermic; q = -1170 kJ **6.4** -48.9 L; 4.96 kJ; -885.2 kJ **6.5** 2N<sub>2</sub>H<sub>4</sub>(l) + N<sub>2</sub>O<sub>4</sub>(l) → 3N<sub>2</sub>(g) + 4H<sub>2</sub>O(g); ΔH = -1049 kJ **6.6** **a** N<sub>2</sub>H<sub>4</sub>(l) + ½N<sub>2</sub>O<sub>4</sub>(l) → ½N<sub>2</sub>(g) + 2H<sub>2</sub>O(g); ΔH = -5.245 × 10<sup>2</sup> kJ **b** 4H<sub>2</sub>O(g) + 3N<sub>2</sub>(g) → N<sub>2</sub>O<sub>4</sub>(l) + 2N<sub>2</sub>H<sub>4</sub>(l); ΔH = 1049 kJ **6.7** -164 kJ **6.8** 1.80 × 10<sup>2</sup> J **6.9** -54 kJ; HCl(aq) + NaOH(aq) → NaCl(aq) + H<sub>2</sub>O(l); ΔH = -54 kJ **6.10** ΔH = -1792 kJ **6.11** ΔH<sub>vap</sub><sup>o</sup> = 44.0 kJ **6.12** ΔH<sup>o</sup> = -138.0 kJ **6.13** ΔH<sup>o</sup> = 61.6 kJ

## CHAPTER 7

**7.1** 767 nm **7.2** 6.58 × 10<sup>14</sup>/s **7.3** 2.0 × 10<sup>-19</sup> J, 2.0 × 10<sup>-17</sup> J, and 2.0 × 10<sup>-15</sup> J; greatest energy: X-ray region; least energy: infrared region **7.4** 103 nm **7.5** 3.38 × 10<sup>-19</sup> J **7.6** λ = 332 pm **7.7** **a** The value of n must be a positive whole number greater than zero. **b** The values of l range from 0 to n - 1. Here, l has a value greater than n. **c** The values for m<sub>l</sub> range from -l to +l. Here, m<sub>l</sub> has a value greater than that of l. **d** The values for m<sub>s</sub> are +½ or -½, not 0.

## CHAPTER 8

8.1 **a** possible **b** possible **c** impossible. There are two electrons in a  $2p$  orbital with the same spin. **d** possible. **e** impossible. Only two electrons are allowed in an  $s$  subshell. **f** impossible. Only six electrons are allowed in a  $p$  subshell.

8.2  $1s^2 2s^2 2p^6 3s^2 3p^6 3d^5 4s^2$  8.3  $4s^2 4p^3$  8.4 Group 4A, Period 6; main-group element

8.6 In order of increasing radius: Be, Mg, Na 8.7 It is more likely that 1000 kJ/mol is the ionization energy for iodine because ionization energies tend to decrease as atomic number increases in a column. 8.8 F

## CHAPTER 9

9.1  $\cdot\text{Mg}\cdot + \cdot\ddot{\text{O}}\cdot \longrightarrow \text{Mg}^{2+} + \left[ \ddot{\text{O}} \right]^{2-}$  9.2 The electron configuration for  $\text{Ca}^{2+}$  is [Ar] and its Lewis symbol is  $\text{Ca}^{2+}$ . The electron configuration for  $\text{S}^{2-}$  is [Ne] $3s^2 3p^6$  and its Lewis symbol is  $\left[ \ddot{\text{S}} \right]^{2-}$ . 9.3 The electron configurations of Pb and  $\text{Pb}^{2+}$

are [Xe] $4f^{14} 5d^{10} 6s^2 6p^2$  and [Xe] $4f^{14} 5d^{10} 6s^2$ , respectively.

9.4 [Ar] $3d^5$  9.5 One would expect  $\text{S}^{2-}$ , because it has two additional electrons. 9.6 In order of increasing ionic radius:  $\text{Mg}^{2+}$ ,  $\text{Ca}^{2+}$ ,  $\text{Sr}^{2+}$  9.7 In order of increasing ionic radius:  $\text{Ca}^{2+}$ ,  $\text{Cl}^-$ ,  $\text{P}^{3-}$  9.8 C—O is the most polar bond.

9.16 97 pm 9.17 123 pm 9.18 -1308 kJ

## CHAPTER 10

10.1 **a** trigonal pyramidal **b** bent **c** tetrahedral 10.2 T-shaped 10.3 **b**, **c** 10.4 **b**; the F atoms are distributed in a tetrahedral arrangement to give a molecule with a dipole moment of zero. 10.5 For the N atom:

N (ground state) = [He]  $\uparrow\downarrow$   $\uparrow$   $\uparrow$   $\uparrow$  and  
 $2s$   $2p$

N (hybridized) = [He]  $\uparrow\downarrow$   $\uparrow$   $\uparrow$   $\uparrow$   
 $sp^3$

Each N—H bond is formed by the overlap of a  $1s$  orbital of a hydrogen atom with one of the  $sp^3$  hybrid orbitals of the nitrogen atom. 10.6 The C atom is  $sp$  hybridized. A carbon-oxygen bond is double and is composed of a  $\sigma$  bond and a  $\pi$  bond. The  $\sigma$  bond is formed by the overlap of a hybrid C orbital with a  $2p$  orbital of O that lies along the axis. The  $\pi$  bond is formed by the sidewise overlap of a  $2p$  on C with a  $2p$  on O. 10.7 The structural formulas for the isomers are as follows:

These compounds exist as separate isomers. If they were interchangeable, one end of the molecule would have to remain fixed as the other rotated. This would require breaking the  $\pi$  bond and a considerable expenditure of energy.

10.8  $\text{KK} \uparrow\downarrow \uparrow\downarrow \uparrow\downarrow \uparrow\downarrow \circ \circ \circ$ ;  
 $\sigma_{2s}$   $\sigma_{2s}^*$   $\pi_{2p}$   $\sigma_{2p}$   $\pi_{2p}^*$   $\sigma_{2p}^*$ ;  
 $\text{KK}(\sigma_{2s})^2(\sigma_{2s}^*)^2(\pi_{2p})^4$ ; diamagnetic; bond order = 2

10.9  $\text{KK} \uparrow\downarrow \uparrow\downarrow \uparrow\downarrow \uparrow\downarrow \circ \circ \circ$ ;  
 $\sigma_{2s}$   $\sigma_{2s}^*$   $\pi_{2p}$   $\sigma_{2p}$   $\pi_{2p}^*$   $\sigma_{2p}^*$ ;  
 $\text{KK}(\sigma_{2s})^2(\sigma_{2s}^*)^2(\pi_{2p})^4(\sigma_{2p})^2$ ; bond order = 3; diamagnetic

## CHAPTER 11

11.1  $1.37 \times 10^3$  kJ;  $4.12 \times 10^3$  g 11.2  $5.30 \times 10^2$  mmHg  
 11.3 43.0 kJ/mol 11.4 **a** Methyl chloride can be liquefied by sufficiently increasing the pressure as long as the temperature is below  $144^\circ\text{C}$ . **b** Oxygen can be liquefied by compression as long as the temperature is below  $-119^\circ\text{C}$ . 11.5 **a** hydrogen bonding, dipole-dipole forces, and London forces **b** London forces **c** dipole-dipole forces and London forces 11.6 In order of increasing vapor pressure we have: butane ( $\text{C}_4\text{H}_{10}$ ), propane ( $\text{C}_3\text{H}_8$ ), and ethane ( $\text{C}_2\text{H}_6$ ). London forces increase with increasing molecular weight. Therefore, one would expect the lowest vapor pressure to correspond to the highest molecular weight. 11.7 Hydrogen bonding is negligible in methyl chloride but strong in ethanol, which explains the lower vapor pressure of ethanol. 11.8 **a** metallic solid **b** ionic solid **c** covalent network solid **d** molecular solid 11.9  $\text{C}_2\text{H}_5\text{OH}$ , molecular;  $\text{CH}_4$ , molecular;  $\text{CH}_3\text{Cl}$ , molecular;  $\text{MgSO}_4$ , ionic. In order of increasing melting point:  $\text{CH}_4$ ,  $\text{CH}_3\text{Cl}$ ,  $\text{C}_2\text{H}_5\text{OH}$ , and  $\text{MgSO}_4$ . 11.10 1 atom 11.11  $6.02 \times 10^{23}$ /mol 11.12 533 pm

## CHAPTER 12

12.1 A dental filling, made up of liquid mercury and solid silver, is a solid solution. 12.2  $\text{C}_4\text{H}_9\text{OH}$ , because of hydrogen bonding. 12.3  $\text{Na}^+$  12.4  $8.45 \times 10^{-3}$  g  $\text{O}_2$ /L 12.5 7.07 g HCl; 27.9 g  $\text{H}_2\text{O}$  12.6 3.09 *m*  $\text{C}_6\text{H}_5\text{CH}_3$  12.7 mole fraction toluene = 0.194; mole fraction benzene = 0.806 12.8 mole fraction methanol = 0.00550; mole fraction ethanol = 0.995 12.9 7.24 *m*  $\text{CH}_3\text{OH}$  12.10 2.96 *M*  $(\text{NH}_2)_2\text{CO}$  12.11 2.20 *m*  $(\text{NH}_2)_2\text{CO}$  12.12  $\Delta P = 1.22$  mmHg; P = 155 mmHg 12.13  $1.89 \times 10^{-1}$  g  $\text{CH}_2\text{OHCH}_2\text{OH}$  12.14 176 amu 12.15 124 amu;  $\text{P}_4$  12.16  $\pi = 3.5$  atm 12.17  $100.077^\circ\text{C}$  12.18  $\text{AlCl}_3$

## A-20 Answers to Exercises

## CHAPTER 13

$$13.1 \frac{\Delta[\text{NO}_2\text{F}]}{\Delta t} = -\frac{\Delta[\text{NO}_2]}{\Delta t}$$

13.2  $1.1 \times 10^{-4} \text{ M/s}$  13.3 zero order in  $[\text{CO}]$ ; second order in  $[\text{NO}_2]$ ; second order overall 13.4 rate =  $k[\text{NO}_2]^2$ ;  $k = 0.71 \text{ L}/(\text{mol}\cdot\text{s})$  13.5 a  $[\text{N}_2\text{O}_5]_t = 1.24 \times 10^{-2} \text{ mol/L}$  b  $t = 4.80 \times 10^3 \text{ s}$  13.6 half-life =  $0.075 \text{ s}$ ; decreases to 50% of initial concentration in  $0.075 \text{ s}$ , to 25% in  $0.151 \text{ s}$  13.7  $E_a = 2.06 \times 10^5 \text{ J/mol}$ ,  $k = 5.80 \times 10^{-2}/(\text{M}^{1/2}\cdot\text{s})$  13.8  $2\text{H}_2\text{O}_2 \longrightarrow 2\text{H}_2\text{O} + \text{O}_2$  13.9 bimolecular 13.10 rate =  $k[\text{NO}_2]^2$  13.11 rate =  $k_1[\text{H}_2\text{O}_2][\text{I}^-]$  13.12 rate =  $k_2(k_1/k_{-1})[\text{NO}]^2[\text{O}_2]$

## CHAPTER 14

14.1 0.57 mol  $\text{CO}$ , 0.57 mol  $\text{H}_2\text{O}$ , 0.43 mol  $\text{CO}_2$ , and 0.43 mol  $\text{H}_2$

$$14.2 \text{ a } K_c = \frac{[\text{NH}_3]^2[\text{H}_2\text{O}]^4}{[\text{NO}_2]^2[\text{H}_2]^7} \quad \text{b } K_c = \frac{[\text{NH}_3][\text{H}_2\text{O}]^2}{[\text{NO}_2][\text{H}_2]^{7/2}}$$

14.3  $\text{CO}(\text{g}) + \text{H}_2\text{O}(\text{g}) \rightleftharpoons \text{H}_2(\text{g}) + \text{CO}_2(\text{g})$ ; 0.57

14.4  $K_c = 2.3 \times 10^{-4}$  14.5  $K_p = 1.24$

14.6  $K_c = \frac{[\text{Ni}(\text{CO})_4]}{[\text{CO}]^4}$  14.7 products; 0.018  $M$

14.8  $Q_c = 0.67$ ; more  $\text{CO}$  will form 14.9 0.0096 moles of  $\text{PCl}_5$  14.10 0.11 mol  $\text{H}_2$ , 0.11 mol  $\text{I}_2$ , 0.78 mol  $\text{HI}$  14.11 0.86  $M \text{ PCl}_5$ , 0.135  $M \text{ PCl}_3$ , 0.135  $M \text{ Cl}_2$  14.12 a in the reverse direction b in the reverse direction 14.13 a no; pressure has no effect. b no c yes 14.14 high temperature 14.15 High temperatures and low pressure would give the best yield of product.

## CHAPTER 15

15.1  $\text{H}_2\text{CO}_3(\text{aq}) + \text{CN}^-(\text{aq}) \rightleftharpoons \text{HCN}(\text{aq}) + \text{HCO}_3^-(\text{aq})$ ;  
acid base acid base

$\text{HCN}$  is the conjugate acid of  $\text{CN}^-$ .

$\text{BF}_3$  is the Lewis acid,  $\text{CH}_3\text{OH}$  is the Lewis base.

$\text{O}^{2-}$  is the Lewis base,  $\text{CO}_2$  is the Lewis acid.

15.3 The reactants are favored. 15.4 a  $\text{PH}_3$  b  $\text{HI}$  c  $\text{H}_2\text{SO}_3$  d  $\text{H}_3\text{AsO}_4$  e  $\text{HSO}_4^-$  15.5 0.250  $M \text{ OH}^-$ ,  $4.0 \times 10^{-14} \text{ M H}^+$  15.6 basic 15.7 1.35 15.8 12.40 15.9  $6.9 \times 10^{-4} \text{ M}$  15.10  $4 \times 10^{-4} \text{ M}$

## CHAPTER 16

16.1  $1.4 \times 10^{-4}$ ; 0.071 16.2  $[\text{H}^+] = [\text{C}_2\text{H}_3\text{O}_2^-] = 1.3 \times 10^{-3} \text{ M}$ ;  $\text{pH} = 2.89$ ; 0.013 16.3 3.24 16.4  $\text{pH} = 1.29$ ;  $[\text{SO}_3^{2-}] = 6.3 \times 10^{-8} \text{ M}$  16.5  $3.3 \times 10^{-6}$  16.6  $5.3 \times 10^{-12} \text{ M}$  16.7 a acidic b neutral c acidic 16.8 a  $1.5 \times 10^{-11}$  b  $2.4 \times 10^{-5}$  16.9  $1.5 \times 10^{-6}$ ; 8.19 16.10  $8.5 \times 10^{-5} \text{ M}$ ;  $8.5 \times 10^{-4}$  16.11 3.63 16.12 5.26 16.13 3.83 16.14 1.60 16.15 7.97 16.16 a 11.28 b 9.26 c 5.22 d 2.23

## CHAPTER 17

17.1 a  $K_{sp} = [\text{Ba}^{2+}][\text{SO}_4^{2-}]$  b  $K_{sp} = [\text{Fe}^{3+}][\text{OH}^-]^3$  c  $K_{sp} = [\text{Ca}^{2+}]^3[\text{PO}_4^{3-}]^2$  17.2  $1.8 \times 10^{-10}$  17.3  $4.5 \times 10^{-36}$  17.4 0.67 g/L 17.5 a  $6.3 \times 10^{-3} \text{ mol/L}$  b  $4.4 \times 10^{-5} \text{ mol/L}$  17.6 Precipitation is expected. 17.7 No precipitate will form. 17.8 silver cyanide 17.9  $1.2 \times 10^{-9} \text{ M}$  17.10 No precipitate will form. 17.11 0.44 mol/L

## CHAPTER 18

18.1 304 J/(mol·K) 18.2 a positive b positive c negative d positive 18.3 537 J/K 18.4  $-888.7 \text{ kJ}$  18.5 130.9 kJ 18.6 All four reactions are spontaneous in the direction written. 18.7 a  $K = P_{\text{CO}_2}$  b  $K = [\text{Pb}^{2+}][\text{I}^-]^2$

$$\text{c } K = \frac{P_{\text{CO}_2}}{[\text{H}^+][\text{HCO}_3^-]}$$

18.8  $1 \times 10^{-23}$  18.9  $5 \times 10^{-12}$  18.10  $9 \times 10^{-2} \text{ atm}$  18.11  $T = 669.5 \text{ K}$ , which is lower than that for  $\text{CaCO}_3$ .

## CHAPTER 19

19.1  $\text{I}_2(\text{s}) + 10\text{NO}_3^-(\text{aq}) + 8\text{H}^+(\text{aq}) \longrightarrow 4\text{H}_2\text{O}(\text{l}) + 2\text{IO}_3^-(\text{aq}) + 10\text{NO}_2(\text{g})$

19.2  $\text{H}_2\text{O}_2(\text{aq}) + 2\text{ClO}_2(\text{aq}) + 2\text{OH}^-(\text{aq}) \longrightarrow 2\text{ClO}_2^-(\text{aq}) + \text{O}_2(\text{g}) + 2\text{H}_2\text{O}(\text{l})$

19.3 anode:  $\text{Ni}(\text{s}) \longrightarrow \text{Ni}^{2+}(\text{aq}) + 2\text{e}^-$ ; cathode:  $\text{Ag}^+(\text{aq}) + \text{e}^- \longrightarrow \text{Ag}(\text{s})$ ; electrons flow from anode to cathode;  $\text{Ag}^+$  flows to Ag;  $\text{Ni}^{2+}$  flows away from Ni.

19.4  $\text{Zn}(\text{s})|\text{Zn}^{2+}(\text{aq})||\text{H}^+(\text{aq})|\text{H}_2(\text{g})|\text{Pt}$

19.5  $\text{Cd}(\text{s}) + 2\text{H}^+(\text{aq}) \longrightarrow \text{Cd}^{2+}(\text{aq}) + \text{H}_2(\text{g})$

19.6  $-2.12 \times 10^4 \text{ J}$  19.7  $\text{NO}_3^-$  19.8 No 19.9 1.10 V

19.10  $-1.4 \times 10^2 \text{ kJ}$  19.11 2.696 V 19.12  $1 \times 10^{19}$

19.13 1.42 V 19.14  $4 \times 10^{-7} \text{ M Ni}^{2+}$

19.15 a  $\text{K}^+(\text{l}) + \text{e}^- \longrightarrow \text{K}(\text{l})$

$2\text{Cl}^-(\text{l}) \longrightarrow \text{Cl}_2(\text{g}) + 2\text{e}^-$

b  $\text{K}^+(\text{l}) + \text{e}^- \longrightarrow \text{K}(\text{l})$

$4\text{OH}^-(\text{l}) \longrightarrow \text{O}_2(\text{g}) + 2\text{H}_2\text{O}(\text{g}) + 4\text{e}^-$

19.16  $\text{Ag}^+(\text{aq}) + \text{e}^- \longrightarrow \text{Ag}(\text{s})$  (cathode)

$2\text{H}_2\text{O}(\text{l}) \longrightarrow \text{O}_2(\text{g}) + 4\text{H}^+(\text{aq}) + 4\text{e}^-$  (anode)

19.17  $2.52 \times 10^{-2} \text{ A}$

19.18  $8.66 \times 10^{-2} \text{ g}$

## CHAPTER 20

20.1  ${}_{19}^{40}\text{K} \longrightarrow {}_{20}^{40}\text{Ca} + {}_{-1}^0\text{e}$  20.2  ${}_{92}^{235}\text{U}$  20.3 a is stable;

b and c are radioactive. 20.4 a positron emission

b beta emission 20.5 a  ${}_{20}^{40}\text{Ca}(\text{d,p}){}_{20}^{41}\text{Ca}$  b  ${}_{12}^{12}\text{C} + {}_1^1\text{H} \longrightarrow$

${}_{13}^{13}\text{C} + {}_1^1\text{H}$  20.6  ${}_{7}^{14}\text{N}$  20.7  $3.2 \times 10^{-5}/\text{s}$  20.8 5.26 y

20.9  $7.82 \times 10^{-10}/\text{s}$ ;  $7.4 \times 10^{-7} \text{ Ci}$  20.10 0.200

20.11  $1.0 \times 10^4 \text{ y}$  20.12 a  $2.58 \times 10^9 \text{ J}$  b 6.25 MeV

## CHAPTER 22

22.1 a pentaamminechlorocobalt(III) chloride b potassium aquapentacyanocobaltate(III) c pentaquaahydroxoiron(III) ion

22.2 a  $\text{K}_4[\text{Fe}(\text{CN})_6]$  b  $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}$  c  $[\text{PtCl}_4]^{2-}$

22.3 a no geometric isomers possible b geometric isomers possible (See Fig. 22.15 for similar example.)

22.4 a no optical isomers possible; b is similar to Figure 22.16.

22.7 530 nm, 500 nm, yes;  $\text{CN}^-$  is a more strongly bonding ligand than  $\text{H}_2\text{O}$ .

### CHAPTER 23

b none    23.3 2-bromobutane    23.4 a 2,3-dimethylbutane  
 b 3-ethyl-2-methylhexane

23.6 a 2,4-dimethyl-2-hexene    b 3-propyl-1-hexene

23.8 *cis*-3-hexene, *trans*-3-hexene

23.9 a propyne    b 3-methyl-1-pentyne

23.11 3-ethyl-3-hexanol    23.12 a dimethyl ether

b methyl ethyl ether

23.13 a 2-pentanone    b butanal

### CHAPTER 24

# Answers to Concept Checks

## CHAPTER 1

**1.1** **a** element **b** compound **c** mixture **1.2** **a** two if you weigh under 100 lb, three if you weigh 100 lb or more **b** A 165-lb person would be reported as weighing  $1.7 \times 10^2$  lb. **c** A 74.8-kg or 165-lb male would weigh 50 kg or 200 lb on the truck scale. **1.3** **a** Meters, decimeters, or centimeters would be appropriate units. **b** approximately 9 m **c**  $39^\circ\text{C}$  would mean that you had a moderate fever. **d** You would probably be comfortable in a  $23^\circ\text{C}$  room. **1.4** You need to perform an experiment that will give you the density of the marcasite and then compare that to the density of gold.

## CHAPTER 2

**2.1** The molecular model on the far right that contains 3 atoms with a ratio of 1:2 **2.2** One would conclude that the atom is made up primarily of a large impenetrable mass with a positive charge. **2.3** They must have similar chemical and/or physical properties. **2.4** Molecular:  $\text{CH}_4$ ,  $\text{Br}_2$ ,  $\text{CH}_4\text{O}$ . Ionic:  $\text{CaCl}_2$ ,  $\text{KNO}_3$ ,  $\text{LiF}$ . Answer **d** is correct. **2.5** **a** ether **b** alcohol **c** carboxylic acid **d** hydrocarbon **2.6** The polyatomic ions that are listed are:  $\text{SO}_4^{2-}$ ,  $\text{NO}_2^-$ , and  $\text{I}_3^-$ . Choice **c** is false. **2.7** Q is likely to be an element in Group 6A.

## CHAPTER 3

**3.1** **a** 1.5 mol **b** 4.5 mol **c** 3.0 mol of  $\text{OH}^-$  since there are 2 mol of  $\text{OH}^-$  per mol of  $\text{Mg}(\text{OH})_2$  **3.2** **a** The total mass of C and H that you collect will be less than the total mass of material you started with. **b** The calculated percent C and H would be less than the real value. **3.3** **a** No, the empirical formula needs to be the smallest whole-number ratio of subscripts. **b** No, the subscripts are not whole numbers. **c** Yes, the empirical and molecular formulas can be the same. **3.4** **a** correct **b** incorrect **c** incorrect **d** correct **e** correct **f** incorrect **g** incorrect **h** correct **3.5** Answer **c** is the best answer considering the information provided in the problem. **3.6** **a**  $\text{X}_2(\text{g}) + 2\text{Y}(\text{g}) \longrightarrow 2\text{XY}(\text{g})$  **b** container 1 **c**  $\text{Y}(\text{g})$

## CHAPTER 4

**4.1** Strong electrolytes:  $\text{NH}_4\text{Cl}$ ,  $\text{MgBr}_2$ , and  $\text{HCl}$ . Answers **b**, **c**, and **e** support the correct choices. **4.2** The left beaker contains the strong electrolyte  $\text{LiI}(\text{aq})$ . The right beaker contains the nonelectrolyte  $\text{CH}_3\text{OH}(\text{aq})$ . **4.3** **a**  $\text{Na}_2\text{SO}_4(\text{aq}) + \text{Sr}(\text{C}_2\text{H}_3\text{O}_2)_2(\text{aq}) \longrightarrow \text{SrSO}_4(\text{s}) + 2\text{NaC}_2\text{H}_3\text{O}_2(\text{aq})$  **b**  $2\text{Na}^+(\text{aq}) + \text{SO}_4^{2-}(\text{aq}) + \text{Sr}^{2+}(\text{aq}) + 2\text{C}_2\text{H}_3\text{O}_2^-(\text{aq}) \longrightarrow \text{SrSO}_4(\text{s}) + 2\text{Na}^+(\text{aq}) + 2\text{C}_2\text{H}_3\text{O}_2^-(\text{aq})$  **c**  $\text{Sr}^{2+}(\text{aq}) + \text{SO}_4^{2-}(\text{aq}) \longrightarrow \text{SrSO}_4(\text{s})$  **4.4**  $\longrightarrow \text{H}_3\text{O}^+(\text{aq}) + \text{ClO}_2^-(\text{aq}), \longrightarrow \text{H}_3\text{O}^+(\text{aq}) + \text{Br}^-(\text{aq})$ . Statement **e** is correct. **4.5** **a**  $\text{MOH}(\text{s})$  is a base. M could be any Group 1 metal. **b** HA is an acid.  $\text{A}^-$  is an anion with

a  $-1$  charge. **c**  $\text{H}_2\text{A}$  is an acid.  $\text{A}^{2-}$  is an anion with a  $-2$  charge. **d**  $\text{M} \longrightarrow \text{Na}^+$ ,  $\text{A} \longrightarrow \text{C}_2\text{H}_3\text{O}_2^-$ ,  $\text{A} \longrightarrow \text{SO}_3^{2-}$ . **4.6** Concentration order:  $\text{A} < \text{C} = \text{D} < \text{B}$ . Leave A alone; add water to fill beaker B; add water to double the volumes of D and C. **4.7** **a** The acid in flask C has three times as many acidic protons as the acid in flask A. The acid in flask B has two times as many acidic protons as the acid in flask A. **b** Yes, if we assume that flask A contains a monoprotic acid.

## CHAPTER 5

**5.1** Since the height of the column is inversely related to the density of the liquid, the column containing the  $\text{H}_2\text{O}$  would be higher. **5.2** **a** Step 1, pressure decrease; Step 2, pressure decrease; total change, final pressure less than starting pressure. **b** Step 1, pressure increase; Step 2, pressure increase; total change, final pressure greater than starting pressure. **5.3** **a** All contain the same amount of gas. **b** Xe flask **c** He flask **d** They would all still have the same number of moles. **5.4** **a** No change in  $\text{H}_2$  pressure. **b** They are equal. **c** The total pressure is the sum of the pressures of the  $\text{H}_2$  and Ar in the container **5.5** Choice II is correct with answer **c** being the best explanation. **5.6** **a** He **b** Raise the temperature of the Ar. **5.7** **a** Pressure would be greater for ideal gas. **b** Pressure would be less for ideal gas. **c** Cannot make a determination because the effect of molecular volume and attractions on the pressure of a real gas is opposite.

## CHAPTER 6

**6.1** Sun's energy is changed to electric energy, to chemical energy (of the battery), and back to electric energy, then to kinetic energy of motor and water, and to potential energy of water. **6.2** **d** **6.3** **c** and **d** are exothermic; **d** is most exothermic **6.4**  $\Delta H_{\text{sub}} = \Delta H_{\text{fus}} + \Delta H_{\text{vap}}$

## CHAPTER 7

**7.1** The wavelength is halved; ultraviolet. **7.2** UV **7.3** The proton speed would be about 2000 times smaller.

## CHAPTER 8

**8.1** 4 **8.2** Mg and Al **8.3** 2A **8.4** As

## CHAPTER 9

**9.1** **a** excited state; not expected **b**  $\text{N}^{2-}$  is not expected. **c** expected configuration **d**  $\text{Na}^{2+}$  is not expected. **e** expected configuration **9.2** **a** has 13 electron pairs; should be 12 **b** correct skeleton structure and distribution of electrons **c** Double bond between F and N atoms is less likely than single bond. **d** no octet on left N atom **e** incorrect skeleton structure **f** no octets on N atoms **9.3** **a** most accurate description **b** Electronegative N atom

is not expected to be in central position. **c** not enough electron pairs to give octets on C and N atoms (would need 7 pairs) **d** not enough electron pairs to give octets on C and N atoms (would need 6 pairs)

## CHAPTER 10

**10.1** The four pairs have a tetrahedral arrangement; the molecular geometry is trigonal pyramidal. **10.2** Molecule Y is likely to be trigonal planar, but trigonal pyramidal or T-shaped geometries are possible. Molecule Z cannot have a trigonal planar geometry, but must be either trigonal pyramidal or T-shaped. **10.3** The single and triple bonds each require a sigma bond orbital, suggesting *sp* hybrids.

## CHAPTER 11

**11.1** **a** (i) slightly lower (ii) higher (iii) more molecules (iv) Evaporation is greater.

(v)

$t = 1$

**b** (i) slightly lower (ii) higher (iii) more molecules (iv) They will be equal.

(v)

$t = 2$

**11.2** Cook it longer because the  $\text{H}_2\text{O}$  temperature would be lower. **11.3** Answer **b** is an incorrect statement.

**11.4** **a** The hydrogen and oxygen would form an explosive mixture. **b** many times greater (more positive) for the wrong reaction **c** Apply Hess's law. **11.5** **a** AB

**b** face-centered cubic

## CHAPTER 12

**12.1** **a** Mo solute, Cr solvent **b**  $\text{MgCl}_2$  solute,  $\text{H}_2\text{O}$  solvent

**c**  $\text{O}_2$  and  $\text{N}_2$  solutes, Ar solvent **12.2** Compound X is a large nonpolar molecule. Compound Y is a molecule that exhibits hydrogen bonding. Applying the like dissolves like concept, compound X will be more soluble in the nonpolar solvent and compound Y will be more soluble in a polar solvent. **12.3** The  $\text{A}^{2+}$  ion must be smaller so it has a greater energy of hydration. **12.4** At high elevations, the partial pressure of  $\text{O}_2$  is so low that not enough dissolves in the water to sustain fish. **12.5** A soluble, chemically similar liquid with a higher vapor pressure than water. **12.6** To prevent water from flowing into the pickle via osmosis. The pickles would be huge and would probably burst. **12.7** Highest to lowest:  $\text{MgCl}_2 > \text{KBr} > \text{Na}_2\text{SO}_4 > \text{NaCl}$ . **12.8** The iron(III)

hydroxide precipitates because the electrons from the negative electrode neutralize the positive charge on the iron(III) hydroxide.

## CHAPTER 13

**13.1** **a** Point A has a faster instantaneous rate. **b** No, it decreases with time. **13.2** **a**  $[\text{Q}] = 0.0 \text{ M}$  slowest (no reaction); the other two are equal in rate because they are zero order with respect to  $[\text{Q}]$ . **b**  $\text{Rate} = k[\text{R}]^2$  **13.3** **a** Rate of aging =  $(\text{diet})^w (\text{exercise})^x (\text{sex})^y (\text{occupation})^z$  **b** Gather a sample of people that have all of the factors the same except one. For example, using the equation given in part **a**, you could determine the effect of diet if you had a sample of people who were the same sex, exercised the same amount, and had the same occupation. You would need to isolate each factor in this fashion to determine the exponent on each factor. **c** 2 **13.4** Second order **13.5** **a** the A + B reaction **b** the E + F reaction **c** exothermic **13.6** **a** It will increase the rate since the activation energy,  $E_a$ , is inversely related to the rate constant,  $k$ . A decrease in  $E_a$  results in an increase in the value of  $k$ . **b** yes **c** No, it should be  $\text{rate} = k[\text{Y}]^2$ .

## CHAPTER 14

**14.1**  $2\text{A} + \text{B} \longrightarrow 2\text{C}$  **14.2** IV with A = red, I with X = red or blue, II with C = blue **14.3** left to right **14.4** It is quadrupled. **14.5** I

## CHAPTER 15

**15.1**  $\text{HCHO}_2(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{CHO}_2^-(\text{aq}) + \text{H}_3\text{O}^+(\text{aq})$  and  $\text{H}_2\text{O}(\text{l}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{H}_3\text{O}^+(\text{aq}) + \text{OH}^-(\text{aq})$ ;  $\text{HCHO}_2(\text{aq})$ ,  $\text{H}_2\text{O}(\text{l})$ ,  $\text{CHO}_2^-(\text{aq})$ ,  $\text{OH}^-(\text{aq})$ , and  $\text{H}_3\text{O}^+(\text{aq})$  **15.2** Acetate ion **15.3** B, A, C **15.4** NaOH,  $\text{NH}_3$ ,  $\text{HC}_2\text{H}_3\text{O}_2$ , HCl

## CHAPTER 16

**16.1** HCN,  $\text{HC}_2\text{H}_3\text{O}_2$ ,  $\text{HNO}_2$ , HF **16.2**  $\text{B}(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{BH}^+(\text{aq}) + \text{OH}^-(\text{aq})$  weak base **16.3** a, b **16.4**  $\text{KNO}_2(\text{aq})$  and  $\text{HNO}_3(\text{aq})$  **16.5** **d** **16.6** **a** Y **b** 3 **c** beaker with 7 HA molecules

## CHAPTER 17

**17.1**  $\text{PbSO}_4$  **17.2**  $\text{NaNO}_3$  **17.3** Picture fewer  $\text{Ag}^+$  and more  $\text{Cl}^-$  ions. **17.4** Magnesium oxalate

## CHAPTER 18

**18.1** It has increased. **18.2** The NO concentration is low at equilibrium. **18.3** **a**  $\Delta G^\circ$  is not changed. **b**  $\Delta G$  increases. **18.4** The concentration of  $\text{NO}_2$  increases with temperature.

## CHAPTER 19

**19.1** No sustainable current would flow. The wire does not contain mobile positively and negatively charged species, which are necessary to balance the accumulation of charges in each of the half-cells. **19.2** **a**  $-0.54 \text{ V}$  **b** No **c** They both would

**A-24** Answers to Concept Checks

be 1.10 V. **19.3** **a** negative **b** Change the concentrations

in a manner to increase  $Q$ , where  $Q = \frac{[\text{Fe}^{2+}]}{[\text{Cu}^{2+}]}$

For example:  $\text{Fe}(s)|\text{Fe}^{2+}(1.10\text{ M})||\text{Cu}^{2+}(0.50\text{ M})|\text{Cu}(s)$ .

**19.4** Many of the ions contained in seawater have very high reduction potentials—higher than  $\text{Fe}(s)$ . This means that spontaneous electrochemical reactions will occur with the  $\text{Fe}(s)$ , causing the iron to form ions and go into solution, while at the same time, the ions in the sea are reduced and plate out on the surface of the iron.

**CHAPTER 20**

**20.1** **a** yes **b** no, since the  ${}^3\text{H}_2\text{O}$  molecule is more massive than  ${}^1\text{H}_2\text{O}$  **c**  ${}^3\text{H}_2\text{O}$  **20.2** the  $\alpha$  particle, since it has the highest RBE **20.3** After 50,000 years, enough half-lives have passed (about 10) that there would be almost no carbon-14 present to detect and measure.

**CHAPTER 21**

**21.1** Given the high energy demands of animals to move and maintain body temperature, breaking the very strong triple bond of  $\text{N}_2$  requires too much energy when compared to the lower-energy double bond of  $\text{O}_2$ . **21.2** because the only intermolecular forces in these materials are very weak van der Waals forces

**CHAPTER 22**

**22.1**  $\text{K}_2[\text{PtCl}_6]$  **22.2**  $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})\text{Br}]\text{Cl}_2$

**22.3** **a** Complexes A and E **b** A and E **c** A and E, B and C

**CHAPTER 23**

**23.2** Blend of 90% 2,2,4-trimethylpentane and 10% heptane

**c** *cis*-2-pentene

**CHAPTER 24**

**24.2** UACGAUGCCUAAGUU

# Answer Section Selected Odd Problems

## CHAPTER 1

**1.25** **a** Two phases: liquid and solid. **b** Three phases: liquid water, solid quartz, and solid seashells. **1.27** **a** You could first immerse the thermometer in an ice-water bath and mark the level at this point as  $0^{\circ}\text{C}$ . Then, immerse the thermometer in boiling water, and mark the level at this point as  $100^{\circ}\text{C}$ . **b** You could make 19 evenly spaced marks on the thermometer between the two original points, each representing a difference of  $5^{\circ}\text{C}$ .

**1.29** **a**  $^{\circ}\text{F} = \left(^{\circ}\text{YS} \times \frac{120^{\circ}\text{F}}{100^{\circ}\text{YS}}\right) - 100^{\circ}\text{F}$  **b**  $-21^{\circ}\text{F}$

**1.31** The box containing the cubes must have a greater mass of wood; hence, it must have a greater density. **1.33** **a** A paper clip has a mass of about 1 g. **b** Answers will vary depending on your particular sample. Keeping in mind that the SI unit for mass is kg, the approximate weights for the items presented in the problem are as follows: a grain of sand,  $1 \times 10^{-5}$  kg; a paper clip,  $1 \times 10^{-3}$  kg; a nickel,  $5 \times 10^{-3}$  kg; a 5.0-gallon bucket of water,  $2.0 \times 10^1$  kg; a brick, 3 kg; a car,  $1 \times 10^3$  kg. **1.37** 6.5 g

**1.39** 55.0 g **1.41** **a** Solid **b** Liquid **c** Gas **d** Solid

**1.43** **a** Physical change **b** Physical change **c** Chemical change **d** Physical change **1.45** Physical change: Liquid mercury is cooled to solid mercury. Chemical changes:

(1) Solid mercury oxide forms liquid mercury metal and gaseous oxygen; (2) glowing wood and oxygen form burning wood (form ash and gaseous products). **1.47** **a** Physical property **b** Chemical property **c** Physical property **d** Physical property **e** Chemical property **1.49** Physical properties: (1) Iodine is solid; (2) the solid has lustrous blue-black crystals; (3) the crystals vaporize readily to a violet-colored gas. Chemical properties: (1) Iodine combines with many metals, such as with aluminum to give aluminum iodide.

**1.51** **a** Physical process **b** Chemical reaction **c** Physical process **d** Chemical reaction **e** Physical process

**1.53** **a** Solution **b** Substance **c** Substance **d** Heterogeneous mixture **1.55** **a** A pure substance with two phases present, liquid and gas. **b** A mixture with two phases present, solid and liquid. **c** A pure substance with two phases present, solid and liquid. **d** A mixture with two phases present, solid and solid. **1.57** **a** 4 **b** 3 **c** 4 **d** 5

**c**  $2\text{HC}_2\text{H}_3\text{O}_2(\text{aq}) + \text{Ca}(\text{OH})_2(\text{aq}) \longrightarrow 2\text{H}_2\text{O}(\text{l}) + \text{Ca}(\text{C}_2\text{H}_3\text{O}_2)_2(\text{aq})$   
 $\text{HC}_2\text{H}_3\text{O}_2(\text{aq}) + \text{OH}^-(\text{aq}) \longrightarrow \text{H}_2\text{O}(\text{l}) + \text{C}_2\text{H}_3\text{O}_2^-(\text{aq})$   
**d**  $\text{NH}_3(\text{aq}) + \text{HNO}_3(\text{aq}) \longrightarrow \text{NH}_4\text{NO}_3(\text{aq})$   
 $\text{NH}_3(\text{aq}) + \text{H}^+(\text{aq}) \longrightarrow \text{NH}_4^+(\text{aq})$

The BaSO<sub>4</sub> can be filtered off, leaving aqueous CuCl<sub>2</sub>, which can be obtained in solid form by evaporation.

The aqueous Ca(C<sub>2</sub>H<sub>3</sub>O<sub>2</sub>)<sub>2</sub> can be converted to the solid form by evaporation.

The aqueous NaNO<sub>3</sub> can be converted to the solid form by evaporation.

The aqueous MgCl<sub>2</sub> can be converted to the solid form by evaporation.

pyramidal and T-shaped b bent 10.45  $\text{CS}_2$  and  $\text{XeF}_4$

10.47 a uses  $sp^3$  orbitals b uses  $sp^3$  orbitals 10.49 a  $sp^3$

b  $sp^2$  c  $sp$  d  $sp^3$  10.51 a The presence of two single

bonds and no lone pairs suggests  $sp$  hybridization. An Hg—Cl

bond is formed by overlapping the Hg  $sp$  hybrid orbital with a

$3p$  orbital of Cl. b The presence of three single bonds and

one lone pair suggests  $sp^3$  hybridization of the P atom. Three

hybrid orbitals each overlap a  $3p$  orbital of a Cl atom to form a

P—Cl bond. The fourth hybrid orbital contains the lone

pair. 10.53 a Because the C is bonded to three other atoms,

it is assumed to be  $sp^2$  hybridized. One  $2p$  orbital remains

unhybridized. The carbon–fluorine bonds are  $\sigma$  bonds formed

by the overlap of an  $sp^2$  hybrid orbital on C with a  $2p$  orbital

on F. The remaining  $sp^2$  hybrid orbital on C overlaps with a  $2p$

orbital on O to form a  $\sigma$  bond. The unhybridized  $2p$  orbital on C

overlaps with a parallel  $2p$  orbital on O to form a  $\pi$  bond. Together,

the  $\sigma$  and  $\pi$  bonds constitute a double bond. b The nitrogen

atoms are  $sp$  hybridized. A  $\sigma$  bond is formed by the

overlap of an  $sp$  hybrid orbital from each N. The remaining  $sp$

hybrid orbitals contain lone pairs of electrons. The two unhy-

bridized  $2p$  orbitals on one N overlap with the parallel unhy-

bridized  $2p$  orbitals on the other N to form two  $\pi$  bonds.

10.55 Each of the N atoms has a lone pair of electrons and

is bonded to two atoms. The N atoms are  $sp^2$  hybridized. The

two possible arrangements of the O atoms relative to one

another are shown below. Because the  $\pi$  bond between the

N atoms must be broken to interconvert these two forms, it is

to be expected that the hyponitrite ion will exhibit *cis-trans* isomerism.

**10.57** **a**  $KK(\sigma_{2s})^2(\sigma_{2s}^*)^2$ , bond order = 0, unstable, diamagnetic  
**b**  $KK(\sigma_{1s})^2(\sigma_{1s}^*)^1$ , bond order = 0.5, stable, paramagnetic  
**c**  $KK(\sigma_{2s})^2(\sigma_{2s}^*)^2(\pi_{2p})^4(\sigma_{2p})^2(\pi_{2p}^*)^1$ , bond order = 2.5, paramagnetic  
**10.59**  $KK(\sigma_{2s})^2(\sigma_{2s}^*)^2(\pi_{2p})^4(\sigma_{2p})^1$ , bond order = 2.5, paramagnetic  
**10.61** **a** bent **b** trigonal planar  
**c** linear **d** octahedral  
**10.63**  $\text{XeF}_2$  and  $\text{CO}_2$  are linear  
**10.65** **a**  $\text{C}_a$  and  $\text{C}_c$ : Three electron pairs around them. They are  $sp^2$  hybridized.  $\text{C}_c$ : Four electron pairs around it. It is  $sp^3$  hybridized.

**b** Both C atoms are bonded to two other atoms and have no lone pairs of electrons. They are  $sp$  hybridized.

**10.67** The *trans* isomer is expected to have a zero dipole moment, whereas the *cis* isomer is not. **10.69** All four hydrogen atoms of  $\text{H}_2\text{C}=\text{C}=\text{CH}_2$  cannot lie in the same plane because the second  $\text{C}=\text{C}$  bond forms perpendicular to the plane of the first  $\text{C}=\text{C}$  bond. By looking at Figure 10.26, you can see how this is so. The second  $\text{C}=\text{C}$  bond forms in the plane of the  $\text{C}-\text{H}$  bonds. Thus, the plane of the  $\text{C}-\text{H}$  bonds on the right side will be perpendicular to the plane of the  $\text{C}-\text{H}$  bonds on the left side. This is shown below using the  $\pi$  orbitals of the two  $\text{C}=\text{C}$  double bonds. **10.71**  $(\sigma_{1s})^2$ , stable  
**10.73**  $KK(\sigma_{2s})^2(\sigma_{2s}^*)^2(\pi_{2p})^4(\sigma_{2p})^2$ , bond order = 3  
**10.75**  $\text{O}^{2+}$  has one antibonding electron less than  $\text{O}_2$ ;  $\text{O}^{2-}$  has one more antibonding electron than in  $\text{O}_2$   
**10.77** The  $\text{O}_2$  ground state is  $KK(\sigma_{2s})^2(\sigma_{2s}^*)^2(\pi_{2p})^4(\sigma_{2p})^2(\pi_{2p}^*)^2$ . To form the first excited state of  $\text{O}_2$ , a  $\sigma_{2p}$  electron is promoted to the  $\pi_{2p}^*$  orbital, giving  $KK(\sigma_{2s})^2(\sigma_{2s}^*)^2(\pi_{2p})^4(\sigma_{2p})^1(\pi_{2p}^*)^3$ . The transition decreases the bond order from 2 to 1. Both the ground state and first excited state are paramagnetic. **10.105**  $\text{XeO}_3\text{Cl}_2$ ; trigonal bipyramidal

**10.107**  $\text{ClF}_5$ ; square pyramidal.

trigonal planar; therefore, the hybridization is  $sp^2$ ;  $\Delta H_f^\circ = -34.5 \text{ kJ/mol}$ ; Resonance energy = 101 kJ/mol

## CHAPTER 19

- 19.25 a no change b no change c The Zn strip would  
 dissolve, and the blue color of the solution would fade,  
 and solid copper would precipitate out of the solution.

- d no change 19.27 The Zn is a sacrificial electrode that  
 keeps the hull from undergoing oxidation by the dissolved ions  
 in seawater. Zn works because it is more easily oxidized than  
 Fe. 19.29 Since there is more zinc present, the oxidation-  
 reduction reactions in the battery will run for a longer period  
 of time. This assumes zinc is the limiting reactant. 19.31 Pick  
 elements or compounds to be reduced and one to be oxidized  
 so that when the half-reactions are added together, the  $E_{\text{cell}}^\circ$   
 is about 0.90 V. For example:

- 19.33 a brighter b dimmer c dimmer d off

## 19.43

Electron flow in circuit is from Zn to Ag.

## CHAPTER 20

- 20.23 a)  $0.1\%$  b) If you had a large quantity of material,  $0.1\%$  still would be a significant quantity. Also, if the material were particularly toxic in addition to being radioactive, the amount would be a significant quantity. 20.25 Some of the expected mass is in the form of energy, the mass defect. 20.27 a) At  $t = 0 \text{ min}$ , the container contains 16 spheres; at  $t = 30 \text{ min}$ , the container contains 2 spheres. b) Incorrect at  $t = 5 \text{ min}$ ; at  $t = 5 \text{ min}$ , there should be fewer than 750 atoms. 20.29 The large, positively charged He nucleus that makes up alpha ( $\alpha$ ) radiation is unable to pass through the atoms that make up solid materials such as wood without coming into contact or being deflected by the nuclei. Gamma ( $\gamma$ ) radiation, however, with its small wavelength and high energy, can pass through large amounts of material without interaction, just as X rays can pass through skin and other soft tissue. 20.31 Irradiation of food atoms with gamma radiation does not result in the creation of radioactive elements; therefore, the food cannot become radioactive. The addition of a radioactive element directly to the meat would make the meat radioactive. Under the right conditions, nuclear bombardment could also lead to the production of radioactive elements. 20.33  ${}^{87}_{37}\text{Rb} \longrightarrow {}^{87}_{38}\text{Sr} + {}^0_{-1}\text{e}$  20.35  ${}^{232}_{90}\text{Th} \longrightarrow {}^{228}_{88}\text{Ra} + {}^4_2\text{He}$  20.37  ${}^{18}\text{F} \longrightarrow {}^{18}\text{O} + {}^0_{+1}\text{e}$  20.39  ${}^{210}_{84}\text{Po} \longrightarrow {}^{206}_{82}\text{Pb} + {}^4_2\text{He}$  20.41 a)  ${}^{122}_{51}\text{Sb}$  b)  ${}^{204}_{85}\text{At}$  c)  ${}^{80}_{37}\text{Rb}$  20.43 a) positron emission or electron capture b) beta emission c) positron emission or electron capture 20.45  ${}^{235}_{92}\text{U}$  decay series;  ${}^{232}_{90}\text{Th}$  decay series. Alpha emission decreases the mass number by 4. Beta emission has no effect upon the mass number. 20.47 a)  ${}^{26}_{12}\text{Mg}(d, \alpha){}^{24}_{11}\text{Na}$  b)  ${}^{16}_8\text{O}(n, p){}^{15}_7\text{N}$  20.49 a)  ${}^{27}_{13}\text{Al} + {}^1_1\text{H} \longrightarrow {}^{25}_{12}\text{Mg} + {}^4_2\text{He}$  b)  ${}^{10}_5\text{B} + {}^4_2\text{He} \longrightarrow {}^{13}_6\text{C} + {}^1_1\text{H}$  20.51  $1.22 \times 10^9 \text{ kJ/mol}$  20.53 a)  ${}^4_2\text{He}$  b)  $\alpha$  20.55 plutonium-239 20.57  $1.79 \times 10^{-9} \text{ s}^{-1}$  20.59  $8.67 \times 10^{-11} \text{ s}^{-1}$  20.61  $1.3 \times 10^{13} \text{ y}$  20.63  $3.84 \times 10^{-12}/\text{s}$  20.65  $2.3 \times 10^2 \text{ Ci}$  20.67  $6.0 \times 10^{-4} \text{ g}$  20.69  $0.574, 3.4 \mu\text{g}$  20.71  $22.0 \text{ s}$  20.73  $44.5 \text{ d}$  20.75  $4.6 \times 10^3 \text{ y}$  20.77  $5.2 \text{ disintegrations}/(\text{min}\cdot\text{g})$  20.79  $-4.37 \times 10^{-9} \text{ g}$  20.81  $-1.688 \times 10^{12} \text{ J}$ ;  $-17.50 \text{ MeV}$  20.83  $3.02184 \text{ amu}$ ;  $32.01 \text{ MeV}$ ;  $5.336 \text{ MeV}$  20.85 Na-20 is expected to decay by electron capture or positron emission. ## CHAPTER 21

- 21.71 It would react with the oxygen by the following equation:  $\text{C}(s) + \text{O}_2(g) \longrightarrow \text{CO}_2(g)$  21.73 The metallic character decreases from left to right and increases going down a column. 21.75 This means aluminum hydroxide reacts with both acids and bases. For example,  $\text{Al}(\text{OH})_3(s) + 3\text{HCl}(aq) \longrightarrow 3\text{H}_2\text{O}(l) + \text{AlCl}_3(aq)$   $\text{Al}(\text{OH})_3(s) + \text{NaOH}(aq) \longrightarrow \text{Na}^+(aq) + \text{Al}(\text{OH})_4^-(aq)$

**21.77** Oxygen is a very electronegative element, and its bonding involves only the *s* and *p* orbitals, in contrast to bonding using the *d* orbitals in sulfur, etc. Molecular oxygen is a reactive gas, but it forms mainly compounds in which its oxidation state is  $-2$ , compared with compounds of sulfur, etc., which exhibit positive oxidation states as well as the  $-2$  state. **21.79** HBr cannot be prepared by adding sulfuric acid to NaBr because the hot, concentrated acid will oxidize the bromide ion to bromine. **21.81**  $\text{Fe}_2\text{O}_3(s) + 3\text{H}_2(g) \longrightarrow 2\text{Fe}(s) + 3\text{H}_2\text{O}(g)$   
**21.83** 36.9 kg Fe **21.85**  $-417.9$  kJ (exothermic)  
**21.87**

**21.89**  $6.55 \times 10^{19}$

**21.95**  ${}_{89}^{227}\text{Ac} \longrightarrow {}_{87}^{223}\text{Fr} + {}_2^4\text{He}$  **21.97** Add  $\text{CO}_3^{2-}$  to each solution. Calcium carbonate will precipitate from the calcium hydroxide solution. **21.99** Add  $\text{Na}_2\text{SO}_4$  to the solution.  $\text{BaSO}_4(s)$  can then be filtered from the solution. The filtrate will contain  $\text{Mg}^{2+}$  ions. **21.101**  ${}_{90}^{230}\text{Th} \longrightarrow {}_{88}^{226}\text{Ra} + {}_2^4\text{He}$

**21.105** 0.35 g  $\text{Ca}(\text{OH})_2$

**21.109** Test portions of solutions of each compound with each other; the results can differentiate the compounds. For example, if one solution is poured into one of the other solutions and gives no precipitate, then that means  $\text{BaCl}_2$  was mixed with  $\text{KOH}$ , and the third solution is  $\text{Al}_2(\text{SO}_4)_3$ . Adding the third solution of  $\text{Al}_2(\text{SO}_4)_3$  to both of the first two solutions will form a precipitate with only  $\text{BaCl}_2$ . [ $\text{Al}_2(\text{SO}_4)_3$  and excess  $\text{KOH}$  form soluble  $\text{Al}(\text{OH})_4^-$ .] If, instead, one solution is poured into one of the other solutions and a precipitate forms, that means  $\text{BaCl}_2$  was mixed with  $\text{Al}_2(\text{SO}_4)_3 \longrightarrow \text{BaSO}_4$ , and the third solution is  $\text{KOH}$ , etc. Thus, all three are identified.

**21.117**  $-4.2 \times 10^9$  kJ **21.119 a**  $-1$  **b**  $+1$  **c**  $-4$

**d**  $+6$  **21.121 a** Each C—H bond is formed by the overlap of a *1s* orbital of a hydrogen atom with one of the singly occupied *sp*<sup>3</sup> hybrid orbitals of the carbon atom. **b** Each As—F bond is formed by the overlap of a *2p* orbital of a fluorine atom with one of the singly occupied *sp*<sup>3</sup> hybrid orbitals formed from the *4s* and *4p* orbitals of the argon atom.

**c** The C=C double bond is a sigma bond formed by the overlap of the *sp*<sup>2</sup> hybrid orbitals of those carbon atoms, and a pi bond formed by the overlap of the unhybridized *p* orbitals.

The single C—C bond is a sigma bond formed by the overlap of the *sp*<sup>2</sup> orbital of the middle carbon and the *sp*<sup>3</sup> orbital of the CH<sub>3</sub> carbon. The other three orbitals of the CH<sub>3</sub> carbon are used to form the C—H bonds by overlapping with the orbital of the hydrogen atom. The C—H bonds on the middle carbon and the CH<sub>2</sub> carbon are formed by the overlap of the *sp*<sup>2</sup> orbital of carbon and the *s* orbital of hydrogen.

**d** Each Si—H bond is formed by the overlap of a *1s* orbital of a hydrogen atom with one of the singly occupied *sp*<sup>3</sup> hybrid orbitals of the silicon atom. **21.123 a** 74.87 kJ **b** 137.15 kJ

**21.125 a**  $\text{CO}_2(g) + \text{Ba}(\text{OH})_2(aq) \longrightarrow \text{BaCO}_3(s) + \text{H}_2\text{O}(l)$   
**b**  $\text{MgCO}_3(s) + 2\text{HBr}(aq) \longrightarrow \text{CO}_2(g) + \text{H}_2\text{O}(l) + \text{MgBr}_2(aq)$

**21.127**  $\text{C}(s) + \text{O}_2(\text{air}) \longrightarrow \text{CO}_2(g)$   
 $\text{CO}_2(g) + \text{NaOH}(aq) \longrightarrow \text{NaHCO}_3(aq)$

$2\text{NaHCO}_3(aq) \xrightarrow{\Delta} \text{Na}_2\text{CO}_3(s) + \text{H}_2\text{O}(l) + \text{CO}_2(g)$

**21.129** Each silicon atom is tetrahedrally bonded to four other silicon atoms. Each bond is formed by the overlap of an *sp*<sup>3</sup> hybrid orbital on each silicon atom to make a sigma bond. **21.131** 10.7 kg

**21.133**

The drawing represents two of the sets of tetrahedra forming a portion of a long chain. There is a net  $-8$  charge on the fragment, which includes two sets of two  $\text{SiO}_3$  units. Thus, the  $(\text{SiO}_3)_2$  unit has a  $-4$  charge. This would have to be balanced by one  $\text{Li}^+$  and one  $\text{Al}^{3+}$  for every two  $\text{SiO}_3$ . Thus, the empirical formula is  $\text{LiAl}(\text{SiO}_3)_2$ . **21.135** 2.53 g

**21.141** tetrahedral; each bond is formed by the overlap of a *4p* orbital from Br with an *sp*<sup>3</sup> hybrid orbital from P.

**21.149 a**  $+6$  **b**  $+6$  **c**  $-2$  **d**  $+4$

**21.153** 56.9 g

## CHAPTER 22

22.31  $[\text{Co}(\text{NH}_3)_4(\text{NO}_2)_2]\text{Cl}$  22.33 "Hexacyano" means that there are six  $\text{CN}^-$  ligands bonded to the iron cation. The Roman numeral II means the oxidation state of the iron cation is +2, so the overall charge of the complex ion is 4-. This requires four potassium ions to counterbalance the 4- charge.

22.37 a +2 b +6 c +2 d +2

22.41 a six b six c six d four

22.43 a +3 b +2 c +2 d +3

22.45 a +3 b  $\text{Cl}^-$  — chloro; en — ethylenediamine;  $\text{NO}_2^-$  — nitrite c 6 d  $-3$  22.47 a Potassium hexafluoroferrate(III)

b Diamminediaquacopper(II) ion

c Ammonium aquapentafluoroferrate(III)

d Dicyanoargentate(I) ion

22.49 a Pentacarbonyliron(0)

b Dicyanobis(ethylenediamine)rhodium(III) ion

c Tetraamminesulfatochromium(III) chloride

d Tetraoxomanganate(VII) ion (Permanganate is the usual name.)

22.51 a  $\text{K}_3[\text{Mn}(\text{CN})_6]$  b  $\text{Na}_2[\text{Zn}(\text{CN})_4]$

c  $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{NO}_3$  d  $[\text{Cr}(\text{NH}_3)_6]_2[\text{CuCl}_4]_3$

b no geometric isomerism c no geometric isomerism

22.55

b no optical isomers 22.57 a two unpaired electrons

b three unpaired electrons c two unpaired electrons

22.59 a eight electrons in square planar field (low spin)

b seven electrons in square planar field (low spin) c five

electrons in tetrahedral field (high spin) d seven electrons

in tetrahedral field (high spin) 22.61 blue-green 22.63 yes;

$\text{H}_2\text{O}$  is a weaker-bonding ligand 22.65 263 kJ/mol

22.67 no d electrons

22.69 three geometric isomers

22.71  $[\text{Cu}^{2+}] = 6.1 \times 10^{-4} \text{ M}$ ;  $[\text{NH}_3] = 2.4 \times 10^{-3} \text{ M}$ ;  
 $[\text{Cu}(\text{NH}_3)^2]^+ = 0.10 \text{ M}$

## CHAPTER 23

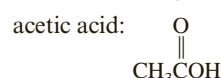

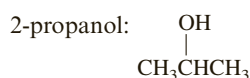

23.19 a The molecules with carbon chains in the  $\text{C}_5 - \text{C}_{11}$  range. b The molecules with carbon chains greater than  $\text{C}_{11}$  will be left in the barrel because they boil at temperatures above  $200^\circ\text{C}$ . (Keep in mind that the heavily branched  $\text{C}_{12}$  chains will have boiled off at or slightly below  $200^\circ\text{C}$ .)

c Low-molecular-weight hydrocarbons have fewer polarizable electrons; therefore, they have weaker London forces than the longer chains and, as a result, boil at a lower temperature.

d The more compact 2,3-dimethylbutane would boil at a lower temperature. 23.21 Since carbon would have more than four bonds in this case,  $\text{CH}_5$  would be in violation of the octet rule. 23.23 a trimethylamine,  $\text{C}_3\text{H}_9\text{N}$ ; acetaldehyde,  $\text{C}_2\text{H}_4\text{O}$ ;

2-propanol,  $\text{C}_3\text{H}_8\text{O}$ ; and acetic acid,  $\text{C}_2\text{H}_4\text{O}_2$

b trimethylamine:  $\text{N}(\text{CH}_3)_3$  acetaldehyde:

c The functional groups in the molecules are trimethylamine, amine (tertiary); acetaldehyde, aldehyde; 2-propanol, alcohol; and acetic acid, carboxylic acid.

23.25 The molecules increase regularly in molecular weight. Therefore, you expect their intermolecular forces (dispersion forces) and thus their melting points to increase. 23.27  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_3$

23.29

23.67 a) Addition of dichromate ion in acidic solution to valeraldehyde (pentanal) will cause the reagent to change from orange to green as the aldehyde is oxidized. Under similar conditions, dipropylketone would not react because it is a ketone.

b) Add  $Br_2$  in  $CCl_4$  each compound. The first compound reacts; the color of  $Br_2$  fades. *m*-Xylene does not react.

23.69 a) ethylene b) toluene c) methylamine d) methanol

23.71 1-butene or 2-butene

## CHAPTER 24

24.25 The corresponding amino-acid sequence is Leu—Tyr—Arg—Gly—His—Thr. The triplet UGA is the code to end the sequence.

24.31 a) would give a polymer having alternating single and double bonds, in which resonance might be expected to give a conducting polymer.

## A-40 Answer Section Selected Odd Problems

24.35 Two dipeptides are possible:

24.37 A:T, 1:1, G:C, 1:1

24.39

# Glossary

The number given in blue at the end of a definition indicates the section where the term was introduced. In some cases, more than one section is indicated. In a few cases, the term is defined in an introductory passage just *before* the section indicated.

**Absolute entropy** see *Standard entropy*.

**Accuracy** the closeness of a single measurement to its true value. (1.5)

**Acid** (Arrhenius definition) a substance that produces hydrogen ions,  $H^+$  (hydronium ion,  $H_3O^+$ ), when it dissolves in water. (4.4 and 15.1); (Brønsted–Lowry definition) the species (molecule or ion) that donates a proton to another species in a proton-transfer reaction. (4.4 and 15.2)

**Acid–base indicator** a dye used to distinguish between acidic and basic solutions by means of the color changes it undergoes in these solutions. (4.4)

**Acid–base titration curve** a plot of the pH of a solution of acid (or base) against the volume of added base (or acid). (16.7)

**Acidic oxide** an oxide that reacts with bases. (8.7)

**Acid-ionization (or acid-dissociation) constant ( $K_a$ )** the equilibrium constant for the ionization of a weak acid. (16.1)

**Activated complex (transition state)** an unstable grouping of atoms that can break up to form products. (13.5)

**Activation energy ( $E_a$ )** the minimum energy of collision required for two molecules to react. (13.5)

**Activity of a radioactive source** the number of nuclear disintegrations per unit time occurring in a radioactive material. (20.3)

**Addition polymer** a polymer formed by linking together many molecules by addition reactions. (24.1)

**Addition reaction** a reaction in which parts of a reactant are added to each carbon atom of a carbon–carbon double bond, which then becomes a C—C single bond. (23.3)

**Aerosol** a colloid consisting of liquid droplets or solid particles dispersed throughout a gas. (12.9)

**Alcohol** a compound obtained by substituting a hydroxyl group ( $-OH$ ) for an  $-H$  atom on a tetrahedral ( $sp^3$  hybridized) carbon atom of a hydrocarbon group. (23.6)

**Aldehyde** a compound containing a carbonyl group with at least one H atom attached to it. (23.6)

**Alkaline dry cell** a voltaic cell that is similar to the Leclanché dry cell but uses potassium hydroxide in place of ammonium chloride. (19.8)

**Alkane** an acyclic saturated hydrocarbon (one without a ring of carbon atoms); a saturated hydrocarbon with the general formula  $C_nH_{2n+2}$ . (23.2)

**Alkene** a hydrocarbon that has the general formula  $C_nH_{2n}$  and contains a carbon–carbon double bond. (23.3)

**Alkyne** an unsaturated hydrocarbon containing a carbon–carbon triple bond. The general formula is  $C_nH_{2n-2}$ . (23.3)

**Allotrope** one of two or more distinct forms of an element in the same physical state. (6.8)

**Alloy** a material with metallic properties that is either a compound or a mixture. (21.2)

**Alpha emission** emission of a  ${}^4_2He$  nucleus, or alpha particle, from an unstable nucleus. (20.1)

**Amide** a compound derived from the reaction of ammonia, or a primary or secondary amine, with a carboxylic acid. (23.7)

**Amide bond** see *Peptide bond*.

**Amine** a compound that is structurally derived by replacing one or more hydrogen atoms of ammonia with hydrocarbon groups. (23.7)

**Amino acid** a compound containing an amino group ( $-NH_2$ ) and a carboxyl group ( $-COOH$ ). (24.3)

**Amorphous solid** a solid that has a disordered structure; it lacks the well-defined arrangement of basic units (atoms, molecules, or ions) found in a crystal. (11.7)

**Ampere (A)** the base unit of current in the International System (SI). (19.11)

**Amphiprotic species** a species that can act as either an acid or a base (that is, it can either lose or gain a proton). (15.2)

**Amphoteric hydroxide** a metal hydroxide that reacts with both bases and acids. (17.5)

**Amphoteric oxide** an oxide that has both acidic and basic properties. (8.7)

**Angstrom (Å)** a non-SI unit of length;  $1 \text{ Å} = 10^{-10} \text{ m}$ . (1.6)

**Angular momentum quantum number ( $l$ )** also known as the azimuthal quantum number. The quantum number that distinguishes orbitals of given  $n$  having different shapes; it can have any integer value from 0 to  $n - 1$ . (7.5)

**Anion** a negatively charged ion. (2.6)

**Anode** the electrode at which oxidation occurs. (19.2)

**Antibonding orbitals** molecular orbitals having zero values in the region between two nuclei and therefore concentrated in other regions. (10.5)

**Aromatic hydrocarbon** a hydrocarbon that contains a benzene ring or similar structural feature. (23.1)

**Arrhenius equation** the mathematical equation  $k = Ae^{-E_a/RT}$ , which expresses the dependence of the rate constant on temperature. (13.6)

**Association colloid** a colloid in which the dispersed phase consists of micelles. (12.9)

**Atmosphere (atm)** a unit of pressure equal to exactly 760 mmHg;  $1 \text{ atm} = 101.325 \text{ kPa}$  (exact). (5.1)

**Atom** an extremely small particle of matter that retains its identity during chemical reactions. (2.1)

**Atomic mass unit (amu)** a mass unit equal to exactly one-twelfth the mass of a carbon-12 atom. (2.4)

**Atomic number ( $Z$ )** the number of protons in the nucleus of an atom. (2.3)

**Atomic orbital** a wave function for an electron in an atom; pictured qualitatively by describing the region of space where there is a high probability of finding the electron. (7.5)

**Atomic radius** as an approximate measure of the radius, the maximum in the radial distribution function of the outer shell of the atom. Also, the value for an atom in a set of covalent radii assigned to atoms in such a way that the sum of the covalent radii of atoms A and B predicts the approximate A—B bond length (often called the covalent radius). (8.6)

**Atomic symbol** a one- or two-letter notation used to represent an atom corresponding to a particular element. A temporary name with a three-letter notation (denoting the atomic number) is given to newly discovered elements. (2.1)

**Atomic theory** an explanation of the structure of matter in terms of different combinations of very small particles (atoms). (2.1)

## A-42 Glossary

- Atomic weight** the average atomic mass for the naturally occurring element, expressed in atomic mass units. (2.4)
- Aufbau principle** see *Building-up principle*.
- Autoionization** a reaction in which two like molecules react to give ions. (15.6)
- Avogadro's law** equal volumes of any two gases at the same temperature and pressure contain the same number of molecules. (5.2)
- Avogadro's number** ( $N_A$ ) the number of atoms in a 12-g sample of carbon-12, equal to  $6.02 \times 10^{23}$  to three significant figures. (3.2)
- Band of stability** the region in which stable nuclides lie in a plot of number of protons against number of neutrons. (20.1)
- Bar** a unit of pressure equal to  $1 \times 10^5$  Pa, slightly less than 1 atm. (5.1)
- Barometer** a device for measuring the pressure of the atmosphere. (5.1)
- Base** (Arrhenius definition) a substance that produces hydroxide ions,  $\text{OH}^-$ , when it dissolves in water. (4.4 and 15.1) (Bronsted-Lowry definition) the species (molecule or ion) that accepts a proton in a proton-transfer reaction. (4.4 and 15.2)
- Base-ionization (or base-dissociation) constant** ( $K_b$ ) the equilibrium constant for the ionization of a weak base. Thus  $K_b$  for  $\text{NH}_3$  is  $1.8 \times 10^{-5}$ . (16.3)
- Basic oxide** an oxide that reacts with acids. (8.7)
- Bayer process** a chemical procedure in which purified aluminum oxide,  $\text{Al}_2\text{O}_3$ , is separated from the aluminum ore bauxite. (21.2)
- Beta emission** emission of a high-speed electron from an unstable nucleus. (20.1)
- Bidentate ligand** a ligand that bonds to a metal atom through two atoms of the ligand. (22.3)
- Bimolecular reaction** an elementary reaction that involves two reactant molecules. (13.7)
- Binary compound** a compound composed of only two elements. (2.8)
- Binary hydride** a compound that contains hydrogen and one other element. (21.7)
- Binding energy (of a nucleus)** the energy needed to break a nucleus into its individual protons and neutrons. (20.6)
- Body-centered cubic unit cell** a cubic unit cell in which there is a lattice point at the center of the unit cell as well as at the corners. (11.7)
- Boiling point** the temperature at which the vapor pressure of a liquid equals the pressure exerted on the liquid (atmospheric pressure, unless the vessel containing the liquid is closed). (11.2)
- Boiling-point elevation** a colligative property of a solution equal to the boiling point of the solution minus the boiling point of the pure solvent. (12.6)
- Bond distance** see *Bond length*.
- Bond enthalpy** the average enthalpy change for the breaking of a bond in a molecule in the gas phase. Also called *bond energy*. (9.11)
- Bonding orbitals** molecular orbitals that are concentrated in the regions between nuclei. (10.5)
- Bonding pair** an electron pair shared between two atoms. (9.4)
- Bond length (bond distance)** the distance between the nuclei in a bond. (9.10)
- Bond order** in a Lewis formula, the number of pairs of electrons in a bond. (9.10) In molecular orbital theory, one-half the difference between the number of bonding electrons and the number of antibonding electrons. (10.5)
- Boyle's law** the volume of a sample of gas at a given temperature varies inversely with the applied pressure. (5.2)
- Bronsted-Lowry concept** a concept of acids and bases in which an acid is the species donating a proton in a proton-transfer reaction, whereas a base is the species accepting a proton in such a reaction. (4.4 and 15.2)
- Buffer** a solution characterized by the ability to resist changes in pH when limited amounts of acid or base are added to it. (16.6)
- Building-up principle (Aufbau principle)** a scheme used to reproduce the electron configurations of the ground states of atoms by successively filling subshells with electrons in a specific order (the building-up order). (8.2)
- Calorie (cal)** a non-SI unit of energy commonly used by chemists, originally defined as the amount of energy needed to raise the temperature of 1 g of water by  $1^\circ\text{C}$ ; now defined as  $1 \text{ cal} = 4.184 \text{ J}$  (exact). (6.1)
- Calorimeter** a device used to measure the heat absorbed or evolved during a physical or chemical change. (6.6)
- Carboxylic acid** a compound containing the carboxyl group,  $-\text{COOH}$ , whose H atom is acidic. (23.6)
- Catalysis** the increase in rate of a reaction as the result of the addition of a catalyst. (13.9)
- Catalyst** a substance that increases the rate of reaction without being consumed in the overall reaction. (2.9 and 13.1)
- Catenation** the covalent bonding of two or more atoms of the same element to one another. (21.8)
- Cathode** the electrode at which reduction occurs. (19.2)
- Cation** a positively charged ion. (2.6)
- Cell potential** the maximum potential difference between the electrodes of a voltaic cell. (19.4)
- Cell reaction** the net reaction that occurs in a voltaic cell. (19.2)
- Celsius scale** the temperature scale in general scientific use. There are exactly 100 units between the freezing point and the normal boiling point of water. (1.6)
- Chain reaction, nuclear** a self-sustaining series of nuclear fissions caused by the absorption of neutrons released from previous nuclear fissions. (20.7)
- Change of state (phase transition)** a change of a substance from one state to another. (11.2)
- Charles's law** the volume occupied by any sample of gas at a constant pressure is directly proportional to the absolute temperature. (5.2)
- Chelate** a complex formed by polydentate ligands. (22.3)
- Chemical change** see *Chemical reaction*.
- Chemical equation** the symbolic representation of a chemical reaction in terms of chemical formulas. (2.9)
- Chemical equilibrium** the state reached by a reaction mixture when the rates of forward and reverse reactions have become equal. (14.1)
- Chemical formula** a notation that uses atomic symbols with numerical subscripts to convey the relative proportions of atoms of the different elements in a substance. (2.6)
- Chemical nomenclature** the systematic naming of chemical compounds. (2.8)
- Chemical property** a characteristic of a material involving its chemical change. (1.4)
- Chemical reaction (chemical change)** a change in which one or more kinds of matter are transformed into a new kind of matter or several new kinds of matter. (1.4) The rearrangement of the atoms present in the reacting substances to give new chemical combinations present in the substances formed by the reaction. (2.1)

- Chemisorption** the binding of a species to a surface by chemical bonding forces. (13.9)
- Chiral** possessing the quality of handedness. A chiral object has a mirror image that is not identical to the object. (22.5)
- Chlor-alkali membrane cell** a cell for the electrolysis of aqueous sodium chloride in which the anode and cathode compartments are separated by a special plastic membrane that allows only cations to pass through it. (19.10)
- Chlor-alkali mercury cell** a cell for the electrolysis of aqueous sodium chloride in which mercury metal is used as the cathode. (19.10)
- cis-trans isomers** see *Geometric isomers*.
- Claus process** a method of obtaining free sulfur by the partial burning of hydrogen sulfide. (21.10)
- Close-packed structure** a crystal structure in which the atoms or other units are packed together as closely as possible. See *Hexagonal close-packed structure and cubic close-packed structure*. (11.8)
- Coagulation** the process by which the dispersed phase of a colloid is made to aggregate and thereby separate from the continuous phase. (12.9)
- Codon** a sequence of three bases in a messenger RNA molecule that serves as the code for a particular amino acid. (24.4)
- Colligative properties** properties that depend on the concentration of solute molecules or ions in a solution but not on the chemical identity of the solute. (12.4)
- Collision theory** the theory that in order for reaction to occur, reactant molecules must collide with an energy greater than some minimum value and with proper orientation. (13.5)
- Colloid** a dispersion of particles of one substance (the dispersed phase) throughout another substance or solution (the continuous phase). (12.9)
- Combination reaction** a reaction in which two substances combine to form a third substance. (4.5)
- Combustion reaction** a reaction of a substance with oxygen, usually with the rapid release of heat to produce a flame. (4.5)
- Common-ion effect** the shift in an ionic equilibrium caused by the addition of a solute that provides an ion that takes part in the equilibrium. (16.5 and 17.2)
- Complementary bases** nucleotide bases that form strong hydrogen bonds with one another. (24.4)
- Complete ionic equation** a chemical equation in which strong electrolytes (such as soluble ionic compounds) are written as separate ions in the solution. (4.2)
- Complex (coordination compound)** a compound consisting either of complex ions and other ions of opposite charge or of a neutral complex species. (22.3)
- Complex ion** an ion formed from a metal ion with a Lewis base attached to it by a coordinate covalent bond. (15.3, 17.5, and 22.3)
- Compound** a substance composed of two or more elements chemically combined. (1.4). A type of matter composed of atoms of two or more elements chemically combined in fixed proportions. (2.1)
- Condensation** the change of a gas to either the liquid or the solid state. (11.2)
- Condensation polymer** a polymer formed by linking many molecules together by condensation reactions. (24.1)
- Condensation reaction** a reaction in which two molecules or ions are chemically joined by the elimination of a small molecule such as water. (21.8)
- Condensed (structural) formula** a structural formula in which the bonds around each carbon atom are not explicitly written. (23.2)
- Conjugate acid** in a conjugate acid-base pair, the species that can donate a proton. (15.2)
- Conjugate acid-base pair** two species in an acid-base reaction, one acid and one base, that differ by the loss or gain of a proton. (15.2)
- Conjugate base** in a conjugate acid-base pair, the species that can accept a proton. (15.2)
- Constitutional (structural) isomers** isomers that differ in how the atoms are joined together (22.5); compounds with the same molecular formula but different structural formulas. (23.2)
- Contact process** an industrial method for the manufacture of sulfuric acid. It consists of the reaction of sulfur dioxide with oxygen to form sulfur trioxide using a catalyst of vanadium(V) oxide, followed by the reaction of sulfur trioxide with water. (21.10)
- Continuous spectrum** a spectrum containing light of all wavelengths. (7.3)
- Control rods** cylinders composed of substances that absorb neutrons, such as boron and cadmium, and can therefore slow a nuclear chain reaction. (20.7)
- Conversion factor** a factor equal to 1 that converts a quantity expressed in one unit to a quantity expressed in another unit. (1.8)
- Coordinate covalent bond** a bond formed when both electrons of the bond are donated by one atom. (9.4)
- Coordination compound** a compound consisting either of complex ions and other ions of opposite charge or of a neutral complex species. (22.3)
- Coordination number** in a crystal, the number of nearest-neighbor atoms of an atom. (11.8) In a complex, the total number of bonds the metal atom forms with ligands. (22.3)
- Copolymer** a polymer consisting of two or more different monomer units. (24.1)
- Coulomb's law** the potential energy obtained in bringing two charges  $Q_1$  and  $Q_2$ , initially far apart, up to a distance  $r$  apart is directly proportional to the product of the charges and inversely proportional to the distance between them. (9.1)
- Covalent bond** a chemical bond formed by the sharing of a pair of electrons between atoms. (9.4)
- Covalent network solid** a solid that consists of atoms held together in large networks or chains by covalent bonds. (11.6)
- Covalent radius** the value for an atom in a set of covalent radii assigned to atoms in such a way that the sum of the covalent radii of atoms A and B predicts the approximate A—B bond length. (8.6 and 9.10)
- Critical mass** the smallest mass of fissionable material in which a chain reaction can be sustained. (20.7)
- Critical pressure** the vapor pressure at the critical temperature; it is the minimum pressure that must be applied to a gas at the critical temperature to liquefy it. (11.3)
- Critical temperature** the temperature above which the liquid state of a substance no longer exists regardless of the pressure. (11.3)
- Crystal field splitting ( $\Delta$ )** the difference in energy between the two sets of  $d$  orbitals on a central metal ion that arises from the interaction of the orbitals with the electric field of the ligands. (22.7)
- Crystal field theory** a model of the electronic structure of transition-metal complexes that considers how the energies of the  $d$  orbitals of a metal ion are affected by the electric field of the ligands. (22.7)
- Crystal lattice** the geometric arrangement of lattice points of a crystal, in which we choose one lattice point at the same location within each of the basic units of the crystal. (11.7)

- Crystalline solid** a solid composed of one or more crystals; each crystal has a well-defined ordered structure in three dimensions. (11.7)
- Cubic close-packed structure (ccp)** a crystal structure composed of close-packed atoms (or other units) with the stacking ABCABCABCA.... It has a face-centered cubic unit cell. (11.8)
- Curie (Ci)** a unit of activity, equal to  $3.700 \times 10^{10}$  disintegrations per second. (20.3)
- Cycloalkane** a cyclic saturated hydrocarbon; that is, a saturated hydrocarbon in which the carbon atoms form a ring; the general formula is  $C_nH_{2n}$ . (23.2)
- Cyclotron** a type of particle accelerator consisting of two hollow, semicircular metal electrodes, called dees (because the shape resembles the letter D), in which charged particles are accelerated by stages to higher and higher kinetic energies. Ions introduced at the center of the cyclotron are accelerated in the space between the two dees. (20.2)
- Dalton's law of partial pressures** the sum of the partial pressures of all the different gases in a mixture is equal to the total pressure of the mixture. (5.5)
- de Broglie relation** the equation  $\lambda = h/mv$  relating the wavelength  $\lambda$  associated with a particle of mass  $m$  and speed  $v$ . (7.4)
- Decomposition reaction** a reaction in which a single compound reacts to give two or more substances. (4.5)
- Degree of ionization** the fraction of molecules that react with water to give ions. (16.1)
- Delocalized bonding** a type of bonding in which a bonding pair of electrons is spread over a number of atoms rather than localized between two. (9.7)
- Density** the mass per unit volume of a substance or solution. (1.7)
- Deoxyribonucleic acid (DNA)** the hereditary constituent of cells; it consists of two polymer strands of deoxyribonucleotide units. (24.4)
- Derived unit** see *SI derived unit*.
- Deuterons** nucleus of a hydrogen-2 atom. (20.2)
- Dextrorotatory** refers to a compound whose solution rotates the plane of polarized light to the right (when looking toward the source of light). (22.5)
- Diamagnetic substance** a substance that is not attracted by a magnetic field or is very slightly repelled by such a field. This property generally means that the substance has only paired electrons. (8.4)
- Diffusion** the process whereby a gas spreads out through another gas to occupy the space uniformly. (5.7)
- Dimensional analysis (factor-label method)** the method of calculation in which one carries along the units for quantities. (1.8)
- Dipole-dipole force** an attractive intermolecular force resulting from the tendency of polar molecules to align themselves such that the positive end of one molecule is near the negative end of another. (11.5)
- Dipole moment** a quantitative measure of the degree of charge separation in a molecule and therefore an indicator of the polarity of the molecule. (10.2)
- Dispersion forces** see *London forces*.
- Displacement reaction (single-replacement reaction)** a reaction in which an element reacts with a compound, displacing another element from it. (4.5)
- Dissociation constant of a complex ion ( $K_d$ )** the reciprocal, or inverse, value of the formation constant. (17.5)
- Double bond** a covalent bond in which two pairs of electrons are shared by two atoms. (9.4)
- Downs cell** a commercial electrochemical cell used to obtain sodium metal by the electrolysis of molten sodium chloride. (19.9)
- Dow process** a commercial method for isolating magnesium from seawater. (21.2)
- Dry cell** see *Alkaline dry cell* and *Zinc-carbon dry cell*.
- Effective nuclear charge** the positive charge that an electron experiences from the nucleus, equal to the nuclear charge but reduced by any shielding or screening from any intervening electron distribution. (8.6)
- Effusion** the process in which a gas flows through a small hole in a container. (5.7)
- Electrochemical cell** a system consisting of electrodes that dip into an electrolyte and in which a chemical reaction either uses or generates an electric current. (19.2)
- Electrolysis** the process of producing a chemical change in an electrolytic cell. (19.9)
- Electrolyte** a substance, such as sodium chloride, that dissolves in water to give an electrically conducting solution. (4.1)
- Electrolytic cell** an electrochemical cell in which an electric current drives an otherwise nonspontaneous reaction. (19.1)
- Electromagnetic spectrum** the range of frequencies or wavelengths of electromagnetic radiation. (7.1)
- Electromotive force (emf)** see *Cell potential*.
- Electron** a very light, negatively charged particle that exists in the region around the atom's positively charged nucleus. (2.2)
- Electron affinity** the energy required to remove an electron from the atom's negative ion (in its ground state); the negative of the energy change obtained when the neutral atom picks up an electron. (8.6)
- Electron capture** the decay of an unstable nucleus by capturing, or picking up, an electron from an inner orbital of an atom. (20.1)
- Electron configuration** the particular distribution of electrons among available subshells. (8.1)
- Electron-dot formula** see *Lewis electron-dot formula*.
- Electronegativity** a measure of the ability of an atom in a molecule to draw bonding electrons to itself. (9.5)
- Electron spin quantum number ( $m_s$ )** see *Spin quantum number*.
- Electron volt (eV)** the quantity of energy that would have to be imparted to an electron (whose charge is  $1.602 \times 10^{-19}$  C) to accelerate it by one volt potential difference. (20.2)
- Element** a substance that cannot be decomposed by any chemical reaction into simpler substances. (1.4)  
A type of matter composed of only one kind of atom, each atom of a given kind having the same properties. (2.1)  
A substance whose atoms all have the same atomic number. (2.3)
- Elementary reaction** a single molecular event, such as a collision of molecules, resulting in a reaction. (13.7)
- Empirical formula (simplest formula)** the formula of a substance written with the smallest integer (whole-number) subscripts. (3.5)
- Emulsion** a colloid consisting of liquid droplets dispersed throughout another liquid. (12.9)
- Enantiomers (optical isomers)** isomers that are nonsuperimposable mirror images of one another. (22.5)
- Endothermic process** a chemical reaction or physical change in which heat is absorbed by the system ( $q$  is positive). (6.3)
- Energy** the potential or capacity to move matter. (6.1)
- Energy levels** specific energy values in an atom. (7.3)
- Enthalpy ( $H$ )** an extensive property of a thermodynamic system defined as the internal energy,  $U$ , plus pressure,  $P$ , times volume,  $V$ :  $H = U + PV$ . (6.3)
- Enthalpy of formation** see *Standard enthalpy of formation*.

- Enthalpy of reaction ( $\Delta H$ )** the change in enthalpy for a reaction at a given temperature and pressure; it equals the heat of reaction at constant pressure. (6.3)
- Entropy ( $S$ )** a thermodynamic quantity that is a measure of how dispersed the energy of a system is among the different possible ways that a system can contain energy. (18.2)
- Equilibrium** see *Chemical equilibrium*.
- Equilibrium constant  $K$**  see *Thermodynamic equilibrium constant*.
- Equilibrium constant  $K_c$**  the value obtained for the equilibrium-constant expression when equilibrium concentrations are substituted. (14.2)
- Equilibrium constant  $K_p$**  an equilibrium constant for a gas reaction, similar to  $K_c$ , but in which concentrations of gases are replaced by partial pressures (in atm). (14.2)
- Equilibrium-constant expression** an expression obtained for a reaction by multiplying the concentrations of products, dividing by the concentrations of reactants, and raising each concentration term to a power equal to the coefficient in the chemical equation. (14.2)
- Equivalence point** the point in a titration when a stoichiometric amount of reactant has been added. (16.7)
- Ester** a compound formed from a carboxylic acid, RCOOH, and an alcohol, R'OH. (23.6)
- Ether** a compound formally obtained by replacing both H atoms of H<sub>2</sub>O by hydrocarbon groups R and R'. (23.6)
- Exact number** a number that arises when you count items or sometimes when you define a unit. (1.5)
- Exchange (metathesis) reaction** a reaction between compounds that, when written as a molecular equation, appears to involve the exchange of parts between the two reactants. (4.3)
- Exclusion principle** see *Pauli exclusion principle*.
- Exothermic process** a chemical reaction or physical change in which heat is evolved or is released from the system ( $q$  is negative). (6.3)
- Experiment** an observation of natural phenomena carried out in a controlled manner so that the results can be duplicated and rational conclusions obtained. (1.2)
- Face-centered cubic unit cell** a cubic unit cell in which there are lattice points at the center of each face of the unit cell in addition to those at the corners. (11.7)
- Factor-label method** see *Dimensional analysis*.
- Faraday constant ( $F$ )** the magnitude of charge on one mole of electrons, equal to  $9.6485 \times 10^4$  C. (19.4)
- Fibrous proteins** proteins that form long coils or align themselves in parallel to form long, water-insoluble fibers. (24.3)
- First ionization energy (first ionization potential)** the minimum energy needed to remove the highest-energy (that is, the outermost) electron from a neutral atom in the gaseous state. (8.6)
- First law of thermodynamics** the change in internal energy of a system,  $\Delta U$ , equals  $q + w$  (heat plus work). (6.2)
- Formal charge** (of an atom in a Lewis formula) the hypothetical charge you obtain for an atom by assuming that bonding electrons are equally shared between bonded atoms and that the electrons of each lone pair belong completely to one atom. (9.9)
- Formation constant (stability constant) of a complex ion ( $K_f$ )** the equilibrium constant for the formation of a complex ion from the aqueous metal ion and the ligands. (17.5)
- Formula** see *Chemical formula* and *Molecular formula*.
- Formula unit** the group of atoms or ions explicitly symbolized in the formula. (2.6)
- Formula weight (FW)** the sum of the atomic weights of all atoms in a formula unit of a compound. (3.1)
- Fractional (isotopic) abundance** the fraction of the total number of atoms that is composed of a particular isotope. (2.4)
- Fractional precipitation** the technique of separating two or more ions from a solution by adding a reactant that precipitates first one ion, then another, and so forth. (17.3)
- Frasch process** a mining procedure in which underground deposits of solid sulfur are melted in place with superheated water, and the molten sulfur is forced upward as a froth using air under pressure. (21.10)
- Free energy ( $G$ )** a thermodynamic quantity defined by the equation  $G = H - TS$ . (18.4)
- Free energy of formation** see *Standard free energy of formation*.
- Freezing** the change of a liquid to the solid state. (11.2)
- Freezing point** the temperature at which a pure liquid changes to a crystalline solid, or freezes. (11.2)
- Freezing-point depression** a colligative property of a solution equal to the freezing point of the pure solvent minus the freezing point of the solution. (12.6)
- Frequency ( $\nu$ )** the number of wavelengths of a wave that pass a fixed point in one unit of time (usually one second). (7.1)
- Frequency factor** the symbol  $A$  in the Arrhenius equation, assumed to be a constant. (13.6)
- Fuel cell** essentially a battery, but it differs by operating with a continuous supply of energetic reactants, or fuel. (19.8)
- Fuel rods** the cylinders that contain fissionable material for a nuclear reactor. (20.7)
- Functional group** a reactive portion of a molecule that undergoes predictable reactions. (2.7 and 23.6)
- Fusion** see *Melting*; see also *Nuclear fusion*.
- Galvanic cell** see *Voltaic cell*.
- Gamma emission** emission from an excited nucleus of a gamma photon, corresponding to radiation with a wavelength of about  $10^{-12}$  m. (20.1)
- Gamma photon** a particle of electromagnetic radiation of short wavelength (about 1 pm, or  $10^{-12}$  m) and high energy. (20.1)
- Gas** the form of matter that is an easily compressible fluid; a given quantity of gas will fit into a container of almost any size and shape. (1.4)
- Geiger counter** a kind of ionization counter used to count particles emitted by radioactive nuclei. It consists of a metal tube filled with gas, such as argon. (20.3)
- Gene** a sequence of nucleotides in a DNA molecule that codes for a given protein. (24.4)
- Geometric isomers** isomers in which the atoms are joined to one another in the same way but differ because some atoms occupy different relative positions in space. (10.4, 22.5, and 23.3)
- Globular proteins** proteins in which long coils fold into compact, roughly spherical shapes. (24.3)
- Goldschmidt process** a method of preparing a metal by reduction of its oxide with powdered aluminum. (21.6)
- Graham's law of effusion** the rate of effusion of gas molecules from a particular hole is inversely proportional to the square root of the molecular weight of the gas at constant temperature and pressure. (5.7)
- Gravimetric analysis** a type of quantitative analysis in which the amount of a species in a material is determined by converting the species to a product that can be isolated completely and weighed. (4.9)
- Group (of the periodic table)** the elements in any one column of the periodic table. (2.5)
- Half-cell** the portion of an electrochemical cell in which a half-reaction takes place. (19.2)
- Half-life ( $t_{1/2}$ )** the time it takes for the reactant concentration to decrease to one-half of its initial value. (13.4) The time it takes for one-half of the nuclei in a sample to decay. (20.4)

- Half-reaction** one of two parts of an oxidation–reduction reaction, one part of which involves a loss of electrons (or increase of oxidation number) and the other a gain of electrons (or decrease of oxidation number). (4.5)
- Hall–Héroult process** the commercial method for producing aluminum by the electrolysis of a molten mixture of aluminum oxide in cryolite,  $\text{Na}_3\text{AlF}_6$ . (21.2)
- Heat** an energy transfer (energy flow) into or out of a thermodynamic system that results from a temperature difference between the system and its surroundings. (6.2)
- Heat capacity ( $C$ )** the quantity of heat needed to raise the temperature of a sample of substance one degree Celsius (or one kelvin). (6.6)
- Heat of formation** see *Standard enthalpy of formation*.
- Heat of fusion (enthalpy of fusion)** the heat needed for the melting of a solid. (11.2)
- Heat of reaction** the heat,  $q$ , absorbed or evolved from a reaction system to retain a fixed temperature of the system under the conditions specified for the reaction (such as a fixed pressure). (6.3)
- Heat of vaporization (enthalpy of vaporization)** the heat needed for the vaporization of a liquid. (11.2)
- Henderson–Hasselbalch equation** an equation relating the pH of a buffer for different concentrations of conjugate acid and base:  $\text{pH} = \text{p}K_a + \log [\text{base}]/[\text{acid}]$ . (16.6)
- Henry's law** the solubility of a gas is directly proportional to the partial pressure of the gas above the solution. (12.3)
- Hess's law of heat summation** for a chemical equation that can be written as the sum of two or more steps, the enthalpy change for the overall equation equals the sum of the enthalpy changes for the individual steps. (6.7)
- Heterogeneous catalysis** the use of a catalyst that exists in a different phase from the reacting species, usually a solid catalyst in contact with a gaseous or liquid solution of reactants. (13.9)
- Heterogeneous equilibrium** an equilibrium that involves reactants and products in more than one phase. (14.3)
- Heterogeneous mixture** a mixture that consists of physically distinct parts, each with different properties. (1.4)
- Heteronuclear diatomic molecule** molecule composed of two different nuclei. (10.6)
- Hexagonal close-packed structure (hcp)** a crystal structure composed of close-packed atoms (or other units) with the stacking ABABABA...; the structure has a hexagonal unit cell. (11.8)
- High-spin complex ion** a complex ion in which there is minimum pairing of electrons in the orbitals of the metal atom. (22.7)
- Homogeneous catalysis** the use of a catalyst in the same phase as the reacting species. (13.9)
- Homogeneous equilibrium** an equilibrium that involves reactants and products in a single phase. (14.3)
- Homogeneous mixture (solution)** a mixture that is uniform in its properties throughout given samples. (1.4)
- Homologous series** a series of compounds in which one compound differs from a preceding one by a fixed group of atoms, for example, a  $-\text{CH}_2-$  group. (23.2)
- Homonuclear diatomic molecule** molecule composed of two like nuclei. (10.6)
- Homopolymer** a polymer whose monomer units are all alike. (24.1)
- Hund's rule** the lowest-energy arrangement of electrons in a subshell is obtained by putting electrons into separate orbitals of the subshell with the same spin before pairing electrons. (8.4)
- Hybrid orbitals** orbitals used to describe bonding that are obtained by taking combinations of atomic orbitals of the isolated atoms. (10.3)
- Hydrate** a compound that contains water molecules weakly bound in its crystals. (2.8)
- Hydration** the attraction of ions for water molecules. (12.2)
- Hydrocarbons** compounds containing only carbon and hydrogen. (2.7 and 23.1)
- Hydrogen bonding** a weak to moderate attractive force that exists between a hydrogen atom covalently bonded to a very electronegative atom and a lone pair of electrons on another small, electronegative atom. It is represented in formulas by a series of dots. (11.5)
- Hydrolysis** the reaction of an ion with water to produce the conjugate acid and hydroxide ion or the conjugate base and hydrogen ion. (16.4)
- Hydrophilic colloid** a colloid in which there is a strong attraction between the dispersed phase and the continuous phase (water). (12.9)
- Hydrophobic colloid** a colloid in which there is a lack of attraction between the dispersed phase and the continuous phase (water). (12.9)
- Hypothesis** a tentative explanation of some regularity of nature. (1.2)
- Ideal gas law** the equation  $PV = nRT$ , which combines all of the gas laws. (5.3)
- Inorganic compounds** compounds composed of elements other than carbon. A few simple compounds of carbon, including carbon monoxide, carbon dioxide, carbonates, and cyanides, are generally considered to be inorganic. (2.8)
- Integrated rate law** a mathematical relationship between concentration and time. (13.4)
- Intermolecular forces** the forces of interaction between molecules. (11.5)
- Internal energy ( $U$ )** the sum of the kinetic and the potential energies of the particles making up a system. (6.1)
- International System of Units (SI)** a particular choice of metric units that was adopted by the General Conference of Weights and Measures in 1960. (1.6)
- Ion** an electrically charged particle obtained from an atom or a chemically bonded group of atoms by adding or removing electrons. (2.6)
- Ionic bond** a chemical bond formed by the electrostatic attraction between positive and negative ions. (9.1)
- Ionic compound** a compound composed of cations and anions. (2.6)
- Ionic equation** see *Complete ionic equation*.
- Ionic radius** a measure of the size of the spherical region around the nucleus of an ion within which the electrons are most likely to be found. (9.3)
- Ionic solid** a solid that consists of cations and anions held together by the electrical attraction of opposite charges (ionic bonds). (11.6)
- Ionization energy** the energy needed to remove an electron from an atom (or molecule). Often used to mean *first ionization energy*. (8.6)
- Ion product ( $Q$ )** the product of ion concentrations in a solution, each concentration raised to a power equal to the number of ions in the formula of the ionic compound. (17.3)
- Ion-product constant for water ( $K_w$ )** the equilibrium value of the ion product  $[\text{H}_3\text{O}^+][\text{OH}^-]$ . (15.6)
- Isoelectronic** refers to different species that have the same number and configuration of electrons. (9.3)
- Isotope dilution** a technique to determine the quantity of a substance in a mixture or the total volume of solution by adding a known amount of an isotope to it. (20.5)
- Isotopes** atoms whose nuclei have the same atomic number but different mass numbers; that is, the nuclei have the same number of protons but different numbers of neutrons. (2.3)

- Joule (J)** the SI unit of energy;  $1 \text{ J} = 1 \text{ kg}\cdot\text{m}^2/\text{s}^2$ . (6.1)
- Kelvin (K)** the SI base unit of temperature; a unit on the absolute temperature scale. (1.6)
- Ketone** a compound containing a carbonyl group with two hydrocarbon groups attached to it. (23.6)
- Kilogram (kg)** the SI base unit for mass; equal to about 2.2 pounds. (1.6)
- Kinetic energy** the energy associated with an object by virtue of its motion. (6.1)
- Kinetic-molecular theory (kinetic theory)** the theory that a gas consists of molecules in constant random motion. (5.6)
- Lattice energy** the change in energy that occurs when an ionic solid is separated into isolated ions in the gas phase. (9.1 and 12.2)
- Law** a concise statement or mathematical equation about a fundamental relationship or regularity of nature. (1.2)
- Law of conservation of energy** energy may be converted from one form to another, but the total quantity of energy remains constant. (6.1)
- Law of conservation of mass** the total mass remains constant during a chemical change (chemical reaction). (1.3)
- Law of definite proportions (law of constant composition)** a pure compound, whatever its source, always contains definite or constant proportions of the elements by mass. (1.4)
- Law of effusion** see *Graham's law of effusion*.
- Law of heat summation** see *Hess's law of heat summation*.
- Law of mass action** the values of the equilibrium-constant expression  $K_c$  are constant for a particular reaction at a given temperature, whatever equilibrium concentrations are substituted. (14.2)
- Law of multiple proportions** when two elements form more than one compound, the masses of one element in these compounds for a fixed mass of the other element are in ratios of small whole numbers. (2.1)
- Law of partial pressures** see *Dalton's law of partial pressures*.
- Lead storage cell** a voltaic cell that consists of electrodes of lead alloy grids; one electrode is packed with a spongy lead to form the anode, and the other is packed with lead dioxide to form the cathode. (19.8)
- Le Châtelier's principle** when a system in equilibrium is disturbed by a change of temperature, pressure, or concentration variable, the system shifts in equilibrium composition in a way that tends to counteract this change of variable. (12.3 and 14.7)
- Leclanché dry cell** see *Zinc-carbon dry cell*.
- Levorotatory** refers to a compound whose solution rotates the plane of polarized light to the left (when looking toward the source of light). (22.5)
- Lewis acid** a species that can form a covalent bond by accepting an electron pair from another species. (15.3)
- Lewis base** a species that can form a covalent bond by donating an electron pair to another species. (15.3)
- Lewis electron-dot formula** a formula in which dots are used to represent valence electrons. (9.4)
- Lewis electron-dot symbol** a symbol in which the electrons in the valence shell of an atom or ion are represented by dots placed around the letter symbol of the element. (9.1)
- Ligand** a Lewis base that bonds to a metal ion to form a complex ion. (17.5 and 22.3)
- Limiting reactant (limiting reagent)** the reactant that is entirely consumed when a reaction goes to completion. (3.8)
- Line spectrum** a spectrum showing only certain colors or specific wavelengths of light. (7.3)
- Liquid** the form of matter that is a relatively incompressible fluid; a liquid has a fixed volume but no fixed shape. (1.4)
- Liter (L)** a unit of volume equal to a cubic decimeter (equal to approximately one quart). (1.7)
- Lithium-iodine battery** a voltaic cell in which the anode is lithium metal and the cathode is an  $\text{I}_2$  complex. (19.8)
- London forces (dispersion forces)** the weak attractive forces between molecules resulting from the small, instantaneous dipoles that occur because of the varying positions of the electrons during their motion about nuclei. (11.5)
- Lone pair (nonbonding pair)** an electron pair that remains on one atom and is not shared. (9.4)
- Low-spin complex ion** a complex ion in which there is more pairing of electrons in the orbitals of the metal atom than in a corresponding high-spin complex ion. (22.7)
- Magic number** the number of nuclear particles in a completed shell of protons or neutrons. (20.1)
- Magnetic quantum number ( $m_l$ )** the quantum number that distinguishes orbitals of given  $n$  and  $l$ —that is, of given energy and shape—but having a different orientation in space; the allowed values are the integers from  $-l$  to  $+l$ . (7.5)
- Manometer** a device that measures the pressure of a gas or liquid in a sealed vessel. (5.1)
- Markownikoff's rule** a generalization stating that the major product formed by the addition of an unsymmetrical reagent such as  $\text{H}-\text{Cl}$ ,  $\text{H}-\text{Br}$ , or  $\text{H}-\text{OH}$  is the one obtained when the  $\text{H}$  atom of the reagent adds to the carbon atom of the multiple bond that already has the greater number of hydrogen atoms attached to it. (23.3)
- Mass** the quantity of matter in a material. (1.3)
- Mass defect** the total nucleon mass minus the atomic mass of a nucleus. (20.6)
- Mass number ( $A$ )** the total number of protons and neutrons in a nucleus. (2.3)
- Mass percentage** parts per hundred parts of the total, by mass. (3.3)
- Mass percentage of solute** the percentage by mass of solute contained in a solution. (12.4)
- Matter** all of the objects around you; whatever occupies space and can be perceived by our senses. (1.3)
- Melting (fusion)** the change of a solid to the liquid state. (11.2)
- Melting point** the temperature at which a crystalline solid changes to a liquid, or melts. (11.2)
- Messenger RNA** a relatively small RNA molecule that can diffuse about the cell and attach itself to a ribosome, where it serves as a pattern for protein synthesis. (24.4)
- Metal** a substance or mixture that has a characteristic luster or shine, is generally a good conductor of heat and electricity, and is malleable and ductile. (2.5 and 21.2)
- Metallic solid** a solid that consists of positive cores of atoms held together by a surrounding "sea" of electrons (metallic bonding). (11.6)
- Metalloid (semimetal)** an element having both metallic and nonmetallic properties. (2.5)
- Metallurgy** the scientific study of the production of metals from their ores and the making of alloys having various useful properties. (21.2)
- Metaphosphoric acids** acids with the general formula  $(\text{HPO}_3)_n$ . (21.9)
- Metastable nucleus** a nucleus in an excited state with a lifetime of at least one nanosecond ( $10^{-9}$  s). (20.1)
- Metathesis reaction** see *Exchange reaction*.
- Meter (m)** the SI base unit of length. (1.6)
- Micelle** a colloidal-sized particle formed in water by the association of molecules or ions each of which has a hydrophobic end and a hydrophilic end. (12.9)

- Millimeters of mercury (mmHg)** a unit of pressure also known as the *torr*. A unit of pressure equal to that exerted by a column of mercury 1 mm high at 0.00°C. (5.1)
- Mineral** a naturally occurring inorganic solid substance or solid solution with definite crystalline form. (21.2)
- Miscible fluids** fluids that mix with or dissolve in each other in all proportions. (12.1)
- Mixture** a material that can be separated by physical means into two or more substances. (1.4)
- Moderator** a substance that slows down neutrons in a nuclear fission reactor. (20.7)
- Molality** the moles of solute per kilogram of solvent. (12.4)
- Molar concentration (molarity),  $M$**  the moles of solute dissolved in one liter (cubic decimeter) of solution. (4.7)
- Molar gas constant ( $R$ )** the constant of proportionality relating the molar volume of a gas to  $T/P$ . (5.3)
- Molar gas volume ( $V_m$ )** the volume of one mole of gas. (5.2)
- Molarity** see *Molar concentration*.
- Molar mass** the mass of one mole of substance. In grams, it is numerically equal to the formula mass in atomic mass units. (3.2)
- Mole (mol)** the quantity of a given substance that contains as many molecules or formula units as the number of atoms in exactly 12 g of carbon-12. The amount of substance containing Avogadro's number of molecules or formula units. (3.2)
- Molecular equation** a chemical equation in which the reactants and products are written as if they were molecular substances, even though they may actually exist in solution as ions. (4.2)
- Molecular formula** a chemical formula that gives the exact number of different atoms of an element in a molecule. (2.6)
- Molecular geometry** the general shape of a molecule, as determined by the relative positions of the atomic nuclei. (10.1)
- Molecularity** the number of molecules on the reactant side of an elementary reaction. (13.7)
- Molecular orbital theory** a theory of the electronic structure of molecules in terms of molecular orbitals, which may spread over several atoms or the entire molecule. (10.5)
- Molecular solid** a solid that consists of atoms or molecules held together by intermolecular forces. (11.6)
- Molecular weight (MW)** the sum of the atomic weights of all the atoms in a molecule. It is, therefore, the average mass of a molecule, expressed in atomic mass units. (3.1)
- Molecule** a definite group of atoms that are chemically bonded together—that is, tightly connected by attractive forces. (2.6)
- Mole fraction** the fraction of moles of a component in the total moles of a mixture. (5.5); the moles of a component substance divided by the total moles of solution. (12.4)
- Monatomic ion** an ion formed from a single atom. (2.8)
- Monodentate ligand** a ligand that bonds to a metal atom through one atom of the ligand. (22.3)
- Monomer** the small molecules that are linked together to form a polymer (2.6); a compound used to make a polymer (and from which the polymer's repeating unit arises). (24.1)
- Nernst equation** an equation relating the cell potential,  $E_{\text{cell}}$ , to its standard potential cell,  $E^{\circ}_{\text{cell}}$ , and the reaction quotient,  $Q$ . At 25°C, the equation is  $E_{\text{cell}} = E^{\circ}_{\text{cell}} - (0.0592/n) \log Q$ . (19.7)
- Net ionic equation** an ionic equation from which spectator ions have been canceled. (4.2)
- Neutralization reaction** a reaction of an acid and a base that results in an ionic compound and possibly water. (4.4)
- Neutron** a particle found in the nucleus of an atom; it has a mass almost identical to that of the proton but no electric charge. (2.3)
- Neutron activation analysis** an analysis of elements in a sample based on the conversion of stable isotopes to radioactive isotopes by bombarding a sample with neutrons. (20.5)
- Nickel–cadmium cell** a voltaic cell consisting of an anode of cadmium and a cathode of hydrated nickel oxide (approximately NiOOH) on nickel; the electrolyte is potassium hydroxide. (19.8)
- Noble-gas core** an inner-shell configuration corresponding to one of the noble gases. (8.2)
- Nomenclature** see *Chemical nomenclature*.
- Nonbonding pair** see *Lone pair*.
- Nonelectrolyte** a substance, such as sucrose, or table sugar ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ), that dissolves in water to give a nonconducting or very poorly conducting solution. (4.1)
- Nonmetal** an element that does not exhibit the characteristics of a metal. (2.5)
- Nuclear bombardment reaction** a nuclear reaction in which a nucleus is bombarded, or struck, by another nucleus or by a nuclear particle. (20.1)
- Nuclear equation** a symbolic representation of a nuclear reaction. (20.1)
- Nuclear fission** a nuclear reaction in which a heavy nucleus splits into lighter nuclei and energy is released. (20.6)
- Nuclear fission reactor** a device that permits a controlled chain reaction of nuclear fissions. (20.7)
- Nuclear force** a strong force of attraction between nucleons that acts only at very short distances (about  $10^{-15}$  m). (20.1)
- Nuclear fusion** a nuclear reaction in which light nuclei combine to give a stabler, heavier nucleus plus possibly several neutrons, and energy is released. (20.6)
- Nucleic acids** polynucleotides folded or coiled into specific three-dimensional shapes. (24.4)
- Nucleotides** the building blocks of nucleic acids. (24.4)
- Nucleus** the atom's central core; it has most of the atom's mass and one or more units of positive charge. (2.2)
- Nuclide** a particular atom characterized by a definite atomic number and mass number. (2.3)
- Number of significant figures** the number of digits reported for the value of a measured or calculated quantity, indicating the precision of the value. (1.5)
- Octet rule** the tendency of atoms in molecules to have eight electrons in their valence shells (two for hydrogen atoms). (9.4)
- Optical isomers (enantiomers)** isomers that are nonsuperimposable mirror images of one another. (22.5)
- Optically active** having the ability to rotate the plane of light waves, either as a pure substance or in solution. (22.5)
- Orbital diagram** a diagram to show how the orbitals of a subshell are occupied by electrons. (8.1)
- Ore** a rock or mineral from which a metal or nonmetal can be economically produced. (21.2)
- Organic compounds** compounds that contain carbon combined with other elements, such as hydrogen, oxygen, and nitrogen. (2.7 and 23.2)
- Osmosis** the phenomenon of solvent flow through a semipermeable membrane to equalize the solute concentrations on both sides of the membrane. (12.7)
- Osmotic pressure** a colligative property of a solution equal to the pressure that, when applied to the solution, just stops osmosis. (12.7)
- Ostwald process** an industrial preparation of nitrogen monoxide starting from the catalytic oxidation of ammonia to nitric oxide. (21.9)
- Overall order of a reaction** the sum of the orders of the reactant species in the rate law. (13.3)

- Oxidation** the part of an oxidation–reduction reaction in which there is a loss of electrons by a species (or an increase in the oxidation number of an atom). (4.5)
- Oxidation number (oxidation state)** either the actual charge on an atom in a substance, if the atom exists as a monatomic ion, or a hypothetical charge assigned by simple rules. (4.5)
- Oxidation–reduction reaction (redox reaction)** a reaction in which electrons are transferred between species or in which atoms change oxidation number. (4.5)
- Oxide** a binary compound with oxygen in the  $-2$  oxidation state. (21.10)
- Oxidizing agent** a species that oxidizes another species; it is itself reduced. (4.5)
- Oxoacid** an acid containing hydrogen, oxygen, and another element (often called the central element). (2.8); a substance in which O atoms (and possibly other electronegative atoms) are bonded to a central atom, with one or more H atoms usually bonded to the O atoms. (9.6)
- Pairing energy ( $P$ )** the energy required to put two electrons into the same orbital. (22.7)
- Paramagnetic substance** a substance that is weakly attracted by a magnetic field; this attraction generally results from unpaired electrons. (8.4)
- Partial pressure** the pressure exerted by a particular gas in a mixture. (5.5)
- Particle accelerator** a device used to accelerate electrons, protons, and alpha particles and other ions to very high speeds. (20.2)
- Pascal (Pa)** the SI unit of pressure;  $1 \text{ Pa} = 1 \text{ kg}/(\text{m}\cdot\text{s}^2)$ . (5.1)
- Pauli exclusion principle** no two electrons in an atom can have the same four quantum numbers. It follows from this that an orbital can hold no more than two electrons and can hold two only if they have different spin quantum numbers. (8.1)
- Peptide (amide) bond** the C–N bond resulting from a condensation reaction between the carboxyl group of one amino acid and the amino group of a second amino acid. (24.3)
- Percentage composition** the mass percentages of each element in a compound. (3.3)
- Percentage yield** the actual yield (experimentally determined) expressed as a percentage of the theoretical yield (calculated). (3.8)
- Period (of the periodic table)** the elements in any one horizontal row of the periodic table. (2.5)
- Periodic law** when the elements are arranged by atomic number, their physical and chemical properties vary periodically. (8.6)
- Periodic table** a tabular arrangement of elements in rows and columns, highlighting the regular repetition of properties of the elements. (2.5)
- Peroxide** a compound with oxygen in the  $-1$  oxidation state. (21.10)
- pH** the negative of the logarithm of the molar hydrogen-ion concentration. (15.8)
- Phase** one of several different homogeneous materials present in the portion of matter under study. (1.4)
- Phase diagram** a graphical way to summarize the conditions under which the different states of a substance are stable. (11.3)
- Phase transition** see *Change of state*.
- Photoelectric effect** the ejection of electrons from the surface of a metal or other material when light shines on it. (7.2)
- Photon** particle of electromagnetic energy with energy  $E$  proportional to the observed frequency of light:  
 $E = h\nu$ . (7.2)
- Physical change** a change in the form of matter but not in its chemical identity. (1.4)
- Physical property** a characteristic that can be observed for a material without changing its chemical identity. (1.4)
- Pi ( $\pi$ ) bond** a bond that has an electron distribution above and below the bond axis. (10.4)
- Planck's constant ( $h$ )** a physical constant with the value  $6.63 \times 10^{-34} \text{ J}\cdot\text{s}$ . It is the proportionality constant relating the frequency of light to the energy of a photon. (7.2)
- Plasma** an electrically neutral gas of ions and electrons. (20.7)
- Polar covalent bond** a covalent bond in which the bonding electrons spend more time near one atom than near the other. (9.5)
- Polyatomic ion** an ion consisting of two or more atoms chemically bonded together and carrying a net electric charge. (2.8)
- Polydentate ligand** a ligand that can bond with two or more atoms to a metal atom. (22.3)
- Polymer** a very large molecule made up of a number of smaller molecules repeatedly linked together. (2.6); a chemical species of very high molecular mass that is made up from many repeating units of low molecular mass. (24.1)
- Polynucleotide** a linear polymer of nucleotide units. (24.4)
- Polypeptide** a polymer formed by the linking of many amino acids by peptide bonds. (24.3)
- Phosphoric acids** acids with the general formula  $\text{H}_{n+2}\text{P}_n\text{O}_{3n-1}$  formed from linear chains of P–O bonds. (21.9)
- Polyprotic acid** an acid that yields two or more acidic hydrogens per molecule. (4.4 and 16.2)
- Positron** a particle that is similar to an electron and has the same mass but has a positive charge. (20.1)
- Positron emission** emission of a positron from an unstable nucleus. (20.1)
- Potential difference** the difference in electrical potential (electrical pressure) between two points. (19.4)
- Potential energy** the energy an object has by virtue of its position in a field of force. (6.1)
- Precipitate** an insoluble solid compound formed during a chemical reaction in solution. (4.3)
- Precision** the closeness of the set of values obtained from identical measurements of a quantity. (1.5)
- Pressure** the force exerted per unit area of surface. (5.1)
- Pressure-volume work** work equal to the negative of the pressure times the change in volume of the system. (6.3)
- Primary structure (of a protein)** the order, or sequence, of the amino-acid units in the protein. (24.3)
- Principal quantum number ( $n$ )** the quantum number on which the energy of an electron in an atom principally depends; it can have any positive integer value: 1, 2, 3, . . . (7.5)
- Product** a substance that results from a chemical reaction. (2.9)
- Protein** a biological polymer of small molecules called amino acids; a polypeptide that has a biological function. (24.3)
- Proton** a particle found in the nucleus of the atom; it has a positive charge equal in magnitude, but opposite in sign, to that of the electron and a mass 1836 times that of the electron. (2.3)
- Pseudo-noble-gas core** the noble-gas core together with  $(n - 1)d^{10}$  electrons. (8.2)
- Qualitative analysis** the determination of the identity of substances present in a mixture. (4.9 and 17.7)
- Quantitative analysis** the determination of the amount of a substance or species present in a material. (4.9)
- Quantum (wave) mechanics** the branch of physics that mathematically describes the wave properties of submicroscopic particles. (7.4)
- Racemic mixture** a mixture of equal amounts of optical isomers. (22.5)

- Rad** the dosage of radiation that deposits  $1 \times 10^{-2}$  J of energy per kilogram of tissue. (20.3)
- Radioactive decay** the process in which a nucleus spontaneously disintegrates, giving off radiation. (20.1)
- Radioactive decay constant ( $k$ )** rate constant for radioactive decay. (20.4)
- Radioactive decay series** a sequence in which one radioactive nucleus decays to a second, which then decays to a third, and so on. (20.1)
- Radioactive tracer** a very small amount of radioactive isotope added to a chemical, biological, or physical system to facilitate study of the system. (20.5)
- Raoult's law** the partial pressure of solvent,  $P_A$ , over a solution equals the vapor pressure of the pure solvent,  $P_A^\circ$ , times the mole fraction of the solvent,  $X_A$ , in solution:  $P_A = P_A^\circ X_A$ . (12.5)
- Rate constant** a proportionality constant in the relationship between rate and concentrations. (13.3)
- Rate-determining step** the slowest step in a reaction mechanism. (13.8)
- Rate law** an equation that relates the rate of a reaction to the concentrations of reactants (and catalyst) raised to various powers. (13.3)
- Reactant** a starting substance in a chemical reaction. (2.9)
- Reaction intermediate** a species produced during a reaction that does not appear in the net equation because it reacts in a subsequent step in the mechanism. (13.7)
- Reaction mechanism** the set of elementary reactions whose overall effect is given by the net chemical equation. (13.7)
- Reaction order** the exponent of the concentration of a given reactant species in the rate law, as determined experimentally. (13.3) See also *Overall order of reaction*.
- Reaction quotient ( $Q_c$ )** an expression that has the same form as the equilibrium-constant expression but whose concentration values are not necessarily those at equilibrium. (14.5)
- Reaction rate** the increase in molar concentration of product of a reaction per unit time or the decrease in molar concentration of reactant per unit time. (13.1)
- Redox reaction** see *Oxidation–reduction reaction*.
- Reducing agent** a species that reduces another species; it is itself oxidized. (4.5)
- Reduction** the part of an oxidation–reduction reaction in which there is a gain of electrons by a species (or a decrease of oxidation number of an atom). (4.5)
- Reduction potential** see *Standard electrode potential*.
- Reference form** the stablest form (physical state and allotrope) of an element under standard thermodynamic conditions. (6.8)
- Rem** a unit of radiation dosage used to relate various kinds of radiation in terms of biological destruction. It equals the rad times a factor for the type of radiation, called the relative biological effectiveness (RBE):  $\text{rems} = \text{rads} \times \text{RBE}$ . (20.3)
- Resonance description** a representation in which you describe the electron structure of a molecule having delocalized bonding by writing all possible electron-dot formulas. (9.7)
- Ribonucleic acid (RNA)** a constituent of cells that is used to manufacture proteins from genetic information. It is a polymer of ribonucleotide units. (24.4)
- Ribosomal RNA** the RNA in a ribosome. (24.4)
- Ribosomes** tiny cellular particles on which protein synthesis takes place. (24.4)
- Roasting** the process of heating a mineral in air to obtain the oxide. (21.2)
- Root-mean-square (rms) molecular speed** a type of average molecular speed, equal to the speed of a molecule having the average molecular kinetic energy. It equals  $\sqrt{3RT/M_m}$ , where  $M_m$  is the molar mass. (5.7)
- Rounding** the procedure of dropping nonsignificant digits in a calculation result and adjusting the last digit reported. (1.5)
- Salt** an ionic compound that is a product of a neutralization reaction. (4.4)
- Salt bridge** a tube of an electrolyte in a gel that is connected to the two half-cells of a voltaic cell; it allows the flow of ions but prevents the mixing of the different solutions that would allow direct reaction of the cell reactants. (19.2)
- Saturated hydrocarbon** a hydrocarbon that has only single bonds between carbon atoms; all carbon atoms are bonded to the maximum number of hydrogen atoms (that is, the hydrocarbon is *saturated* with hydrogen). A saturated hydrocarbon molecule can be cyclic or acyclic. (23.1)
- Saturated solution** a solution that is in equilibrium with respect to a given dissolved substance. (12.2)
- Scientific notation** the representation of a number in the form  $A \times 10^n$ , where  $A$  is a number with a single nonzero digit to the left of the decimal point and  $n$  is an integer, or whole number. (1.5)
- Scintillation counter** a device that detects nuclear radiations from flashes of light generated in a material by the radiation. (20.3)
- Second (s)** the SI base unit of time. (1.6)
- Secondary structure (of a protein)** the relatively simple coiled or parallel arrangement of a protein molecule. (24.3)
- Second law of thermodynamics** the total entropy of a system and its surroundings always increases for a spontaneous process. Also, for a spontaneous process at a given temperature, the change in entropy of the system is greater than the heat divided by the absolute temperature. (18.2)
- Self-ionization** see *Autoionization*.
- Semimetal** see *Metalloid*.
- Shell model of the nucleus** a nuclear model in which protons and neutrons exist in levels, or shells, analogous to the shell structure that exists for electrons in an atom. (20.1)
- SI** see *International System*.
- SI base units** the SI units of measurement from which all others can be derived. (1.6)
- SI derived unit** a unit derived by combining SI base units. (1.7)
- SI prefix** a prefix used in the International System to indicate a power of 10. (1.6)
- Sigma ( $\sigma$ ) bond** a bond that has a cylindrical shape about the bond axis. (10.4)
- Significant figures** those digits in a measured number (or in the result of a calculation with measured numbers) that include all certain digits plus a final digit having some uncertainty. (1.5)
- Silica** a covalent network solid of  $\text{SiO}_2$  in which each silicon atom is covalently bonded in tetrahedral directions to four oxygen atoms; each oxygen atom is in turn bonded to another silicon atom. (21.8)
- Silicate** a compound of silicon and oxygen (with one or more metals) that may be formally regarded as a derivative of silicic acid,  $\text{H}_4\text{SiO}_4$  or  $\text{Si}(\text{OH})_4$ . (21.8)
- Silicone** a polymer that contains chains or rings of Si—O with one or more of the bonding positions on each Si atom occupied by an organic group. (21.8)
- Simple cubic unit cell** a cubic unit cell in which lattice points are situated only at the corners of the unit cell. (11.7)
- Simplest formula** see *Empirical formula*.
- Single bond** a covalent bond in which a single pair of electrons is shared by two atoms. (9.4)
- Single-replacement reaction** see *Displacement reaction*.
- Sol** a colloid that consists of solid particles dispersed in a liquid. (12.9)

- Solid** the form of matter characterized by rigidity; a solid is relatively incompressible and has fixed shape and volume. (1.4)
- Solubility** the amount of a substance that dissolves in a given quantity of solvent (such as water) at a given temperature to give a saturated solution. (12.2)
- Solubility product constant ( $K_{sp}$ )** the equilibrium constant for the solubility equilibrium of a slightly soluble (or nearly insoluble) ionic compound. (17.1)
- Solute** in the case of a solution of a gas or solid dissolved in a liquid, the gas or solid; in other cases, the component in smaller amount. (12.1)
- Solution** see *Homogeneous mixture*.
- Solvay process** an industrial method for obtaining sodium carbonate from sodium chloride and limestone. (21.4)
- Solvent** in a solution of a gas or solid dissolved in a liquid, the liquid; in other cases, the component in greater amount. (12.1)
- Specific heat capacity (specific heat)** the quantity of heat required to raise the temperature of one gram of a substance by one degree Celsius (or one kelvin) at constant pressure. (6.6)
- Spectator ion** an ion in an ionic equation that does not take part in the reaction. (4.2)
- Spectrochemical series** an arrangement of ligands according to the relative magnitudes of the crystal field splittings they induce in the  $d$  orbitals of a metal ion. (22.7)
- Spin quantum number ( $m_s$ )** the quantum number that refers to the two possible orientations of the spin axis of an electron; its possible values are  $+\frac{1}{2}$  and  $-\frac{1}{2}$ . (7.5)
- Spontaneous fission** the spontaneous decay of an unstable nucleus in which a heavy nucleus of mass number greater than 89 splits into lighter nuclei and energy is released. (20.1)
- Spontaneous process** a physical or chemical change that occurs by itself. (18.2)
- Stability constant (of a complex)** see *Formation constant*.
- Standard cell potential ( $E^\circ_{\text{cell}}$ )** the potential of a voltaic cell operating under standard-state conditions (solute concentrations are 1  $M$ , gas pressures are 1 atm, and the temperature has a specified value—usually 25°C). (19.5)
- Standard electrode potential ( $E^\circ$ )** the electrode potential when the concentrations of solutes are 1  $M$ , the gas pressures are 1 atm, and the temperature has a specified value—usually 25°C. (19.5)
- Standard enthalpy of formation (standard heat of formation),  $\Delta H_f^\circ$**  the enthalpy change for the formation of one mole of a substance in its standard state from its elements in their reference forms and in their standard states. (6.8)
- Standard enthalpy of reaction ( $\Delta H^\circ$ )** the enthalpy change for a reaction in which reactants in their standard states yield products in their standard states. (6.8)
- Standard (absolute) entropy ( $S^\circ$ )** the entropy value for the standard state of a species. (18.3)
- Standard free energy of formation ( $\Delta G_f^\circ$ )** the free-energy change that occurs when one mole of substance is produced from its elements in their reference forms (usually the stablest states) at 1 atm and at a specified temperature (usually 25°C). (18.4)
- Standard heat of formation** see *Standard enthalpy of formation*.
- Standard state** the standard thermodynamic conditions (1 atm and usually 25°C) chosen for substances when listing or comparing thermochemical data. (6.8)
- Standard temperature and pressure (STP)** the reference conditions for gases, chosen by convention to be 0°C and 1 atm. (5.2)
- State function** a property of a system that depends only on its present state, which is determined by variables such as temperature and pressure and is independent of any previous history of the system. (6.3)
- States of matter** the three forms that matter can commonly assume—solid, liquid, and gas. (1.4)
- Steam-reforming process** an industrial preparation in which steam and hydrocarbons from natural gas or petroleum react at high temperature and pressure in the presence of a catalyst to form carbon monoxide and hydrogen. (21.7)
- Stereoisomers** isomers in which the atoms are bonded to each other in the same order but that differ in the precise arrangement of the atoms in space. (22.5)
- Stoichiometry** the calculation of the quantities of reactants and products involved in a chemical reaction. (3.6)
- Strong acid** an acid that ionizes completely in water; it is a strong electrolyte. (4.4 and 15.1)
- Strong base** a base that is present in aqueous solution entirely as ions, one of which is  $\text{OH}^-$ ; it is a strong electrolyte. (4.4 and 15.1)
- Strong electrolyte** an electrolyte that exists in solution almost entirely as ions. (4.1)
- Structural isomers** see *Constitutional isomers*.
- Sublimation** the change of a solid directly to the vapor. (11.2)
- Substance** a kind of matter that cannot be separated into other kinds of matter by any physical process. (1.4)
- Substitution reaction** a reaction in which a part of the reacting molecule is substituted for an H atom on a hydrocarbon or a hydrocarbon group. (23.2)
- Substrate** the substance whose reaction an enzyme catalyzes. (13.9)
- Superoxide** a binary compound with oxygen in the  $-\frac{1}{2}$  oxidation state; it contains the superoxide ion,  $\text{O}_2^-$ . (21.10)
- Supersaturated solution** a solution that contains more dissolved substance than does a saturated solution; the solution is not in equilibrium with the solid substance. (12.2)
- Surface tension** the energy required to increase the surface area of a liquid by a unit amount. (11.4)
- Surroundings** everything in the vicinity of a thermodynamic system. (6.2)
- System** see *Thermodynamic system*.
- Termolecular reaction** an elementary reaction that involves three reactant molecules. (13.7)
- Tertiary structure (of a protein)** the structure associated with the way the protein coil is folded. (24.3)
- Theoretical yield** the maximum amount of product that can be obtained by a reaction from given amounts of reactants. (3.8)
- Theory** a tested explanation of basic natural phenomena. (1.2)
- Thermochemical equation** the chemical equation for a reaction (including phase labels) in which the equation is given a molar interpretation, and the enthalpy of reaction for these molar amounts is written directly after the equation. (6.4)
- Thermodynamic equilibrium constant ( $K$ )** the equilibrium constant in which the concentrations of gases are expressed in partial pressures in atmospheres, whereas the concentrations of solutes in liquid solutions are expressed in molarities. (18.6)
- Thermodynamic system** the substance or mixture of substances that we single out for study (perhaps including the vessel) in which a change occurs. (6.2)
- Third law of thermodynamics** a substance that is perfectly crystalline at 0 K has an entropy of zero. (18.3)
- Titration** a procedure for determining the amount of substance  $A$  by adding a carefully measured volume of a solution with known concentration of  $B$  until the reaction of  $A$  and  $B$  is just complete. (4.10)
- Torr** see *Millimeters of mercury*.
- Transfer RNA (tRNA)** a small RNA molecule; it binds to a particular amino acid, carries it to a ribosome, and then attaches itself (through base pairing) to a messenger RNA codon. (24.4)

**Transition elements** the B columns of elements in the periodic table. (2.5); the *d*-block transition elements in which a *d* subshell is being filled. (8.2); those metallic elements that have an incompletely filled *d* subshell or easily give rise to common ions that have incompletely filled *d* subshells. (22.1)

**Transition state** see *Activated complex*.

**Transition-state theory** a theory that explains the reaction resulting from the collision of two molecules in terms of an activated complex (transition state). (13.5)

**Transmutation** the change of one element to another by bombardment of the nucleus of the element with nuclear particles or nuclei. (20.2)

**Transuranium element** an element with atomic number greater than that of uranium ( $Z = 92$ ), the naturally occurring element of greatest  $Z$ . (20.2)

**Triple bond** a covalent bond in which three pairs of electrons are shared by two atoms. (9.4)

**Triple point** the point on a phase diagram representing the temperature and pressure at which three phases of a substance coexist in equilibrium. (11.3)

**Tyndall effect** the scattering of light by colloidal-size particles. (12.9)

**Uncertainty principle** a relation stating that the product of the uncertainty in position and the uncertainty in momentum (mass times speed) of a particle can be no smaller than Planck's constant divided by  $4\pi$ . (7.4)

**Unimolecular reaction** an elementary reaction that involves one reactant molecule. (13.7)

**Unit** a fixed standard of measurement. (1.5)

**Unit cell** the smallest boxlike unit (each box having faces that are parallelograms) from which you can imagine constructing a crystal by stacking the units in three dimensions. (11.7)

**Unsaturated hydrocarbon** a hydrocarbon that has at least one double or triple bond between carbon atoms; not all carbon atoms are bonded to the maximum number of hydrogen atoms (that is, the hydrocarbon is *unsaturated* with hydrogen). (23.1)

**Unsaturated solution** a solution that is not in equilibrium with respect to a given dissolved substance and in which more of the substance can dissolve. (12.2)

**Valence bond theory** an approximate theory to explain the electron pair or covalent bond in terms of quantum mechanics. (10.3)

**Valence electron** an electron in an atom outside the noble-gas or pseudo-noble-gas core. (8.2)

**Valence-shell electron-pair repulsion (VSEPR) model** predicts the shapes of molecules and ions by assuming that the valence-shell electron pairs are arranged about each atom so that electron pairs are kept as far away from one another as possible, thus minimizing electron-pair repulsions. (10.1)

**van der Waals equation** an equation that is similar to the ideal gas law but includes two constants, *a* and *b*, to account for deviations from ideal behavior. (5.8)

**van der Waals forces** a general term for those intermolecular forces that include dipole–dipole and London forces. (11.5)

**Vaporization** the change of a solid or a liquid to the vapor. (11.2)

**Vapor pressure** the partial pressure of the vapor over the liquid, measured at equilibrium at a given temperature. (5.5 and 11.2)

**Vapor-pressure lowering** a colligative property equal to the vapor pressure of the pure solvent minus the vapor pressure of the solution. (12.5)

**Viscosity** the resistance to flow that is exhibited by all liquids and gases. (11.4)

**Volt (V)** the SI unit of potential difference. (19.4)

**Voltaic cell (galvanic cell)** an electrochemical cell in which a spontaneous reaction generates an electric current. (19.1)

**Volumetric analysis** a method of analysis based on titration. (4.10)

**Wavelength ( $\lambda$ )** the distance between any two adjacent identical points of a wave. (7.1)

**Wave mechanics** see *Quantum mechanics*.

**Weak acid** an acid that is only partly ionized in water; it is a weak electrolyte. (4.4 and 15.1)

**Weak base** a base that is only partly ionized in water; it is a weak electrolyte. (4.4 and 15.1)

**Weak electrolyte** an electrolyte that dissolves in water to give a relatively small percentage of ions. (4.1)

**Work** an energy transfer (or energy flow) into or out of a thermodynamic system whose effect on the surroundings is equivalent to moving an object through a field of force. (6.2)

**Zinc–carbon (Leclanché) dry cell** a voltaic cell that has a zinc can as the anode; a graphite rod in the center, surrounded by a paste of manganese dioxide, ammonium and zinc chlorides, and carbon black, is the cathode. (19.8)

 Amino group, 849  
 Ammonia, 114*t*  
   aqueous, 114  
   boiling point of, 372  
   classification of, 117  
   common-ion effect of, 566  
   diluting, 134, 134*f*  
   dipole moment of, 324  
   electrostatic potential map of, 48*t*  
   Haber process, 88–91, 757–758, 758*f*  
   heat of reaction from production of, 198  
   industrial production of, 515, 515*f*  
   Lewis electron-dot formula for, 283–284  
   lone pair of, 316  
   manufacture of, 442  
   molecular formula of, 48*t*  
   molecular geometry of, 314  
   molecular model of, 48*t*  
   oxidation of, 209, 517*f*  
   properties of, 144*t*  
   reaction with boron trifluoride, 526  
   reaction with carbon dioxide, 607, 608  
   reaction with copper sulfate, 582*f*  
   reaction with hydrochloric acid, 523, 523*f*, 525–526  
   reaction with sulfuric acid, 119  
   structural formula of, 48*t*  
   synthesis of, 500, 508–509  
   thermochemical equation for synthesis of, 195  
   titration by hydrochloric acid, 577–579  
   as weak base, 118  
   as weak electrolyte, 105, 107  
 Ammonium chloride, 388  
 Ammonium dichromate, 182*f*  
 Ammonium ion, 56  
 Ammonium nitrate, 79, 80, 411  
   reaction with barium hydroxide, 210  
   reaction with barium hydroxide octahydrate, 186–187, 186*f*, 191  
 Ammonium perchlorate, 212  
 Ammonium salts, 53  
   reaction with barium hydroxide, 183, 183*f*  
 Amontons, Guillaume, 155  
 Amontons's law, 155  
 Amorphous solid, 380  
 Ampere (A), 675–676  
 Amphiprotic species, 524  
 Amphoteric hydroxides, 599–600

## A-56 Index

- Calorimeters, 199–202, 200*f*  
 Calvin, Melvin, 705  
 Camphor  
   boiling-point-elevation and freezing-point-depression constants of, 424*t*  
   molecular weight of, 426–427  
 Cancer therapy, 2, 706  
 Capacitance, 322  
 Capillary rise, 366, 366*f*  
 Caraway, 320, 321*f*  
 Carbohydrates, 721  
 Carbon, 721, 750–752  
   allotropes, 750–751  
   bonding of, 812  
   buckminsterfullerene, 47, 751, 756, 756*f*  
   carbonates, 752  
   carbon black, 751  
   compounds, 752*t*  
   determining percentage in compound, 80–82, 80*f*  
   diamond structure of, 309*f*  
   electron configuration of, 253  
   forms of, 747, 747*f*  
   ionization energy of, 263*t*  
   isotopes of, 39*f*  
   molecular structure, 47  
   orbital diagram of, 326  
   oxides of, 751–752  
   reaction with oxygen, 35  
   standard enthalpies of formation for, 207*t*  
   standard entropy of, 616*t*  
   standard free energies of formation for, 621*t*  
   thermodynamic quantities for, A8  
 Carbon-11, 709  
 Carbon-12, 39*f*, 73, 689  
 Carbon-13, 39*f*, 689  
 Carbon-14, 688, 689  
   radioactive dating and, 702–704  
 Carbonate ion, electron structure of, 292–293  
 Carbonates, 752  
   in acid-base reactions, 121, 121*t*  
 Carbon black, 751  
 Carbon dioxide, 35, 58, 266, 751  
   bond dipoles in, 323  
   decomposition of, 203  
   dry ice, 350*f*, 520*f*  
   effusion rate of, 173–174  
   greenhouse effect and, 178–179, 178*f*, 179, 179*f*  
   liquid, 350  
   phase diagram of, 362*f*  
   pressure change and solubility of, 412  
   properties of, 144*t*, 365*t*  
   reaction with ammonia, 607, 608  
   reaction with calcium hydroxide, 742, 742*f*  
   reaction with magnesium, 739, 739*f*  
   reaction with sodium hydroxide, 80, 80*n*, 733  
   supercritical, 364  
   test for, 741, 752*f*  
   triple point of, 362  
 Carbon disulfide, boiling-point-elevation and freezing-point-depression constants of, 424*t*  
 Carbon-hydrogen bonds, hybrid orbitals and, 327  
 Carbonic acid, 121, 551–552, 752  
 Carbon-12 mass scale, 40  
 Carbon monoxide, 58, 751  
   burning of, 624  
   conversion of coal to, 211  
   effect of temperature change in formation of, 513–514  
   properties of, 144*t*  
   reaction with hydrogen, 489–490  
   reaction with nitrogen dioxide, 468–469, 470  
 Carbon-oxygen bond, 322–323  
 Carbon tetrachloride, 355, 469  
   entropy change of vaporization of, 614  
   nonpolarity of, 322*f*  
   properties of, 365*t*  
 Carbonyl chloride, 296–297  
 Carbonyl chloride (phosgene), 290  
 Carbonyl group, 836  
 Carboplatin, 2  
 Carboxyl group, 849  
 Carboxylic acid group, 544*f*  
 Carboxylic acids, 52*t*, 837, 838*t*  
   thermodynamic quantities for, A8  
 Cardiac studies, using radioactive isotopes, 707–708, 708*f*  
 Carlsbad Cavern, 596  
 $\beta$ -Carotene, 344  
 Carothers, Wallace Hume, 843, 845–846, 845*f*  
 Carrier, 13  
 Catalysis, 478–481  
   enzyme, 481  
   heterogeneous, 479–480  
   homogeneous, 479  
 Catalysts, 64, 442, 778  
   effect on chemical equilibrium, 516–517  
   heterogeneous, 744*f*  
   surface area of, 443  
   transition elements and, 778  
 Catalytic converter, 480, 481*f*  
 Catalytic cracking, 819  
 Catalytic hydrogenation, 479–480, 480*f*, 820  
 Catalytic methanation, 487, 488, 489*f*, 496  
 Catenation, 750  
 Cathode, 35–36, 644  
 Cathode rays, 35–36, 35*n*, 36*f*  
 Cathode reaction, 671  
 Cathodic protection, 667–668, 667*f*, 668*f*  
 Cation, 270, 281  
   common, of transition elements, 54*t*  
   defined, 49  
   transition-metal, 278–279, 278*f*  
 Cationics, 436, 436*f*  
 Caustic soda, 735  
 Cavendish, Henry, 747  
 Caves, limestone, 583, 596  
 CD players, 226–227, 227*f*  
 Cell  
   coupling of reactions in, 624, 625*f*  
   osmosis and, 430  
 Cell membrane, model of, 437*f*  
 Cell potentials, 647–649  
   calculating, 654–656  
   defined, 648  
   dependent on concentration, 660–663  
   determining pH from, 661–663  
   equilibrium constants from, 657–659  
   free-energy change and, 657–659  
   standard, 649–656  
 Celluloid, 842  
 Cellulose nitrate (guncotton), 842  
 Celsius scale, 20–21, 20*f*  
 Centimeter ruler, 15*f*  
 Cerium, 781  
 Cerium selenate, 410  
 Cesium  
   electronegativity of, 286  
   thermodynamic quantities for, A8  
 Cesium chloride, structure of, 387–388, 388*f*  
 Chadwick, James, 39, 692  
 Chain reaction, of nuclear fission, 714–715, 715*f*  
 Chalcogens, properties of, 267. *See also* Group 6A (chalcogens)  
 Change of state, 351. *See also* Phase transitions  
 Charcoal, 747  
 Charge  
   calculating amount, from amount of product in electrolysis, 676  
   calculating amount of product from amount of, in electrolysis, 676–677  
 Charles, Jacques Alexandre, 149  
 Charles's law, 149–151, 151  
   molecular description of, 168–170  
 Chelate, 788  
 Chelate stability, 790  
 Chemical analysis, with radioactive isotopes, 705–706  
 Chemical bonds, 270  
   carbon and, 812  
   compared with intermolecular forces, 367*t*  
   infrared spectroscopy and vibrations of, 305–306  
   in metals, 728–730  
   molecular orbital theory of, 336–346  
   multiple bonding, 331–336  
   in nitroglycerin, 285  
   peptide, 851–852  
   valence bond theory, 325–331  
   *See also* Covalent bonds; Ionic bonds  
 Chemical change, 10. *See also* Chemical reactions  
 Chemical equations, 63–67  
   balancing, 64–67  
   complete ionic, 108, 109  
   defined, 63  
   molar interpretation of, 88–89  
   molecular, 108  
   net ionic, 108, 109–111  
   writing, 63–64, 469  
 Chemical equilibrium, 486–519  
   altering in gaseous reactions, 507–517  
   choosing optimum conditions, 514–515  
   defined, 488  
   as dynamic equilibrium, 487–490  
   effects of catalysts on, 516–517  
   equilibrium constants, 490–497, 500–507  
   heterogeneous, 497–499  
   homogeneous, 497  
   Le Châtelier's principle and, 507–517  
   pressure changes, 510–513  
   reaction conditions and, 507–517  
   removing products/adding reactants, 508–510  
   temperature changes, 513–514  
   *See also* Acid-base equilibria; Equilibrium constants ( $K$ ); Solubility equilibria  
 Chemical formulas, 46–51  
   calculating formula mass from, 72–73  
   calculating formula weight from, 72  
   from composition, 82–86  
   defined, 46–47  
   determining, 78–88  
   of ionic substances, 48–51  
   mass of element from, 74–75  
   mass percentages from, 78–80  
   of molecular substances, 47–48  
   naming compounds and, 56–57, 59  
   naming hydrate from, 62  
   percentage composition from, 78  
   using elemental analysis, 82–84  
   *See also* Empirical formulas; Molecular formulas  
 Chemical kinetics, 442. *See also* Reaction rates  
 Chemical nomenclature, 53, 55  
   of alkanes, 827–831  
   of alkenes, 831–832  
   of alkynes, 831–832  
   of aromatic hydrocarbons, 833  
   of coordination compounds, 789–793  
   of hydrocarbons, 827–833  
 Chemical property, defined, 10  
 Chemical reactions, 6*n*, 32, 102–153  
   acid-base reactions, 114–122  
   amounts of substances in, 89–93  
   defined, 32  
   exchange reactions, 112  
   in ionic solutions, 103–111  
   oxidation-reduction reactions, 122–131  
   precipitation reactions, 111–114  
   quantitative analysis and, 135–140  
   types of, 111  
   working with solutions, 131–135  
   *See also* Heats of reaction; Reaction mechanisms; Reaction rates; *specific reactions*

 combustion in oxygen, 95, 95*f*  
 combustion of, 212  
 determining percentage in compound, 80–82, 80*f*  
 emission spectrum of, 216*f*  
 Haber process and, 748  
 ionization energy of, 263*t*  
 ions, 277  
 isotopes, 748  
 preparation of, 747–749  
 properties of, 266, 747–749  
 reactions and compounds, 749–750  
 reaction with carbon monoxide, 489–490  
 reaction with iodine, 506–507  
 reaction with nitrogen monoxide, 450  
 reaction with oxygen, 40  
 rocket fuels and, 212  
 standard enthalpies of formation for, 207*t*  
 standard entropy of, 616*t*  
 standard free energies of formation for, 621*t*  
 thermodynamic quantities for, A9  
 Hydrogenation, 749  
 catalytic, 820  
 Hydrogen atom  
 Bohr theory of, 222–227  
 orbital energies for, 234*f*  
 Hydrogen bomb, 717  
 Hydrogen bonding, 367, 370–375  
 complementary bases and, 858*f*  
 in water, 396  
 between water and ethanol molecules, 407*f*  
 Hydrogen bromide, 770  
 Hydrogen chloride, 77, 770  
 bonding in, 326, 326*f*  
 dipole-dipole forces and, 367, 368*f*  
 dipole moment of, 322  
 molecular model of, 286*f*  
 reaction with water, 528  
 vibration of, 305*f*  
 Hydrogen chloride fountain, 770*f*  
 Hydrogen chloride gas, 104, 105–106  
 Hydrogen cyanide, 77, 559  
 Hydrogen electrode, 646, 646*f*  
 Hydrogen fluoride, 372, 532  
 Hydrogen fluorine, 343*f*  
 Hydrogen fountain, 173, 173*f*  
 Hydrogen fuel cell, 665, 665*f*  
 Hydrogen gas  
 collection of gas over water and, 165*f*, 166  
 properties of, 144*t*  
 reaction with nitrogen monoxide, 476–477  
 Hydrogen iodide, 770  
 decomposition of, 494–495  
 formation of, 467–468  
 Hydrogen ion, 116  
 Hydrogen molecule  
 bonding in, 326, 326*f*  
 bonding orbitals in, 336, 337*f*  
 bond order in, 338  
 covalent bonding of, 281–282, 281*f*  
 potential-energy curve for, 283*f*  
 Hydrogen nucleus, 522*n*  
 Hydrogen peroxide, 64, 76, 78, 452–453  
 decomposition of, 479, 480*f*  
 molecular formula of, 47, 82  
 molecular model of, 82*f*  
 reaction with hydrobromic acid, 442, 443*f*  
 Hydrogen sulfide, 58, 596–597, 602*n*, 766–767  
 properties of, 144*t*  
 Hydrogen sulfites, 767  
 Hydrologic cycle, 397, 397*f*  
 Hydrolysis, 558  
 preparation of sodium hydroxide by, 541*f*  
 Hydronium ion, 116, 116*n*, 521–522, 522*f*, 637  
 autoionization of water and, 533–535  
 calculating concentration from pH, 539  
 calculating pH from concentration of, 538  
 concentration in weak acids, 544  
 concentrations in solutions of strong acid or base, 534–537  
 Hydrophilic colloids, 433–434  
 Hydrophobic colloids, 433–434  
 Hydroxide ion  
 autoionization of water and, 533–535  
 concentrations in solutions of strong acid or base, 534–537  
 Hydroxides, 118  
 amphoteric, 599–600  
 Hydroxyapatite, 594–595  
 Hydroxyl groups, 370–371  
 Hypochlorite ion, 55, 771  
 Hypochlorous acid, 771  
 Hypothesis, 4–5  
 Ice  
 melting, 610, 613  
 structure of, 396, 396*f*  
 Ice melt, 425  
 Ideal gas equation, 176  
 Ideal gas law, 155–160  
 calculations using, 156–160  
 deriving empirical gas laws from, 155–156  
 gas density and, 157–160  
 kinetic theory and, 166–170  
 Ideal solution, 422  
 Ignarro, Louis, 154  
 Immiscible liquids, 402, 403*f*, 406*f*  
 Indium, 742  
 Indium oxide, 266  
 Industrial ceramics, 744  
 Infrared radiation, 219, 220*n*  
 Infrared spectrometer, 448  
 Infrared spectroscopy, 305–306  
 Initial-rate method, 451, 453  
 Initiator, 843  
 Inner-transition elements, 44, 249, 778  
 Inorganic compounds, 53  
 In phase, 393–394  
 Insecticides, 769  
 Instantaneous dipoles, 368–369  
 Instantaneous rate of reaction, 443–444, 444*f*  
 Insulin, 849  
 Integrated rate law, 454–455  
 Intensive property, 650  
 Intercept, A6  
 Interconversions of energy, 184, 184*f*  
 Intermolecular forces, 367–375  
 compared with chemical bonds, 367*t*  
 dipole-dipole forces, 367  
 effect on gas pressure, 176*f*  
 hydrogen bonding, 370–375  
 ideal gas law and, 167*n*  
 London (dispersion) forces, 367–369  
 in molecular solids, 376, 376*t*  
 polar molecules and, 325  
 properties of liquids and, 369–370  
 solids and, 376, 376*t*  
 van der Waals forces, 367  
 vapor pressure and, 374  
 Internal energy, 186  
 change of, 188–189  
 International System of units. *See* SI units  
 International Union of Pure and Applied Chemistry (IUPAC)  
 nomenclature for coordination compounds, 789–793  
 nomenclature for hydrocarbons, 827–831  
 periodic table conventions of, 43  
 on standard pressure, 146*n*, 206*n*  
 Iodic acid, 641  
 Iodide ion, oxidation of, 452–453  
 Iodine, 11*f*, 769  
 properties of, 267  
 reaction with acetone, 450  
 reaction with hydrogen, 506–507  
 standard enthalpies of formation for, 207*t*  
 standard entropy of, 616*t*  
 standard free energies of formation for, 621*t*  
 sublimation of, 352*f*  
 thermodynamic quantities for, A9

- Iodine-131, 708  
 decay of, 700, 700f  
 Iodine atoms, 33f  
 Iodine pentafluoride, molecular geometry of, 319, 319f  
 Ion  
 in aqueous solutions, 103–111, 104f  
 complex, 526  
 defined, 48  
 electron configurations of, 276–279  
 main-group element, 276–277  
 monatomic, 277  
 polyatomic, 54–57, 278  
 spectator, 109  
 standard enthalpies of formation for, 210  
 surrounding charged colloidal particles, 434f  
 thermodynamic quantities for, A7–A11  
 transition-metal, 278–279  
 Ion-dipole force, 407–408, 408f  
 Ion exchange, water and, 397  
 Ionic bonds, 270–281  
 defined, 270  
 describing, 270–276  
 electron configurations and, 276–279  
 energy involved in, 272–273  
 ionic radii and, 279–281  
 lattice energies from Born-Haber cycle, 274  
 Lewis electron-dot symbols, 271–272  
 of main-group elements, 276–277  
 of polyatomic ions, 278  
 properties of ionic substances, 275–276  
 in solids, 387–389  
 of transition-metal ions, 278–279  
 Ionic compounds  
 defined, 49  
 evolving gases when treated with acids, 121, 121t  
 naming, 53–57  
 neutralization reaction and, 119  
 solubility rules for, 107t  
 Ionic equations, 629  
 complete, 108, 109  
 net, 108, 109–111  
 Ionic equilibrium, 583n  
 Ionic hydrides, 749  
 Ionic liquids, 275  
 Ionic radii, 279–281  
 of main-group elements, 280t  
 Ionic solids  
 crystalline, 387–389  
 defined, 376  
 in electrolytes, 104  
 properties of, 376t, 380t  
 solubility of, 104  
 Ionic solutions, 103–111, 407–410  
 colligative properties of, 431–432  
 electrical conductivity of, 103, 104–105  
 ionic equations for, 109–111  
 molecular equations for, 108  
 motion of ions in, 104f  
 solubility rules for, 106–108, 107t  
 strong and weak electrolytes, 105–106  
 Ionic species, writing Lewis formula for, 290–291  
 Ionic substances  
 chemical formulas of, 48–51  
 mole of, 74  
 properties of, 275–276  
 Ionic theory of solutions, 103–108  
 Ionization  
 acid, 544–551  
 base, 555–558  
 of polyprotic acid, 551–555  
 Ionization energy (I. E.), 251, 260–263  
 atomic number vs., 261f  
 electronegativity and, 286  
 of first ten elements, 263t  
 of transition elements, 781, 781t  
 Ion product, 590–591

   calculating cell potentials, 654–656  
   cell potential, 647–649  
   commercial, 663–668  
   construction of, 642–645  
   defined, 642  
   dependence of cell potential on concentration,  
   660–663  
   equilibrium constants for cell potentials,  
   657–659  
   half-cells in, 642–645  
   list of standard electrode potentials, 652*t*  
   Nernst equation and, 660–661  
   notation for, 645–647  
   standard cell potentials, 649–656  
   standard electrode potentials, 649–656  
   strengths of oxidizing/reducing agents,  
   651–654  
   writing cell reactions for, 646–647  
   *See also* Cell potentials; Standard electrode  
   potentials  
 Volt (V), 647  
 Volume  
   calculating molarity from, 132  
   calculating volume of reactant needed,  
   137–138  
   pressure-volume work, 191–192  
   relating amount of gas and, 153  
   relating pressure of gas to, 146–149, 147*f*,  
   148*f*  
   relating temperature and pressure of gas and,  
   151–153  
   relating temperature of gas and, 149–151,  
   149*f*  
   relationship of U.S. and metric units, 27*t*  
   SI derived unit, 22, 22*t*  
   using density to relate mass and, 24  
 Volumetric analysis, 137–140

## A-74 Index

- Volumetric flask, 22*f*  
 von Laue, Max, 250, 395  
 VSEPR model. *See* Valence-shell electron-pair repulsion (VSEPR) model  
 Vulcanization, 844
- Waage, Peter, 492  
 Walker, John, 197  
 Washing soda, 52, 736*f*. *See also* Sodium carbonate  
 Water, 396–397  
   amphiprotic character of, 524  
   autoionization of, 533–535  
   boiling-point-elevation and freezing-point-depression constants of, 424*t*  
   bonding in, 330–331  
   collecting gases over, 164–166, 165*f*  
   density of, 23, 23*f*, 396, 396*f*  
   dipole moment of, 323  
   dissolution of sodium chloride in, 9–10, 10*f*, 103–104  
   electrical conductivity of, 104  
   electrolysis of, 672, 749  
   electrostatic potential map of, 48*t*  
   formula for, 40*n*  
   formula unit of, 49  
   greenhouse effect and, 178*f*  
   half-reactions involving, 670–675  
   hard, 397  
   heating curve for, 356*f*  
   hydrogen bonding in, 372–373, 372*f*, 396, 407*f*  
   hydroxyl group, 370, 371*f*  
   ion-dipole forces and, 408*f*  
   ion-product constant for, 534  
   liquid, 610  
   mixing octane with, 406  
   mixing with methanol, 407  
   molecular formula of, 48*t*  
   molecular model of, 48*t*  
   molecular weight of, 71  
   phase changes in, 610  
   phase diagram for, 361*f*  
   polarity of, 322*f*  
   properties of, 365*t*, 396  
   reaction with ethyl acetate, 447  
   reaction with hydrogen chloride, 528  
   reaction with sodium metal, 239*f*, 720*f*  
   solubility of alcohols in, 407, 407*t*  
   specific heat and molar heat capacities of, 199*t*  
   standard enthalpy of formation of liquid, 206  
   states of, 8  
   structural formula of, 47, 48*t*  
   surface tension of, 366*f*  
   triple point of, 361*n*  
   vapor-pressure lowering of, 421  
   vapor pressure of, 165, 165*t*, 353*f*, A7  
 Water-gas reaction, 211, 748  
 Water glass, 754  
 Water softeners/softening, 397, 741–742  
 Waterston, John James, 167  
 Water strider, 365*f*

 Zinc(II) ions, 603–604  
 Zinc iodide, 70*f*, 75–76  
 Zinc metal  
   reaction with hydrochloric acid, 192, 192*f*  
   reaction with nitric acid, 639–641  
 Zinc sulfide, 98, 122  
 Zirconium, 738, 781  
 Zwitterions, 851

## UNIT CONVERSIONS

### LENGTH

SI base unit = meter, m

- 1 Å =  $10^{-10}$  m = 100 pm  
 1 in = 2.54 cm (exact)  
 1 cm = 0.3937 in  
 1 yd = 0.9144 m (exact)  
 1 m = 1.0936 yd  
 1 mi = 1.6093 km  
 1 km = 0.6214 mi  
 1 mi = 5280 ft

### VOLUME

SI derived unit = cubic meter, m<sup>3</sup>

- 1 L = 1 dm<sup>3</sup> (exact)  
 1 mL = 1 cm<sup>3</sup> (exact)  
 1 L = 1.0567 qt  
 1 in<sup>3</sup> = 16.387064 cm<sup>3</sup> (exact)  
 1 gal = 3.785411784 L (exact)  
 1 gal = 4 qt (exact)  
 1 qt = 16 fluid oz (exact)

### MASS

SI base unit = kilogram, kg

- 1 amu =  $1.660538921 \times 10^{-27}$  kg  
 1 lb = 453.59237 g (exact)  
 1 kg = 2.2046 lb  
 1 lb = 16 oz (exact)  
 1 ton = 907.18474 kg (exact)  
 1 ton = 2000 lb (exact)  
 1 metric ton =  $10^3$  kg (exact)  
 1 metric ton = 2204.6 lb

### ENERGY

SI derived unit = joule, J

- 1 J = 1 kg·m<sup>2</sup>/s<sup>2</sup> (exact)  
 1 J = 0.2390 cal  
 1 J = 1 C V = 1 coulomb volt (exact)  
 1 cal = 4.184 J (exact)  
 1 eV =  $1.6022 \times 10^{-19}$  J  
 1 eV/molecule = 96.4853 kJ/mol  
 1 J =  $9.4781 \times 10^{-4}$  Btu

### TEMPERATURE

SI base unit = kelvin, K

- 0 K =  $-273.15^\circ\text{C}$   
 0 K =  $-459.67^\circ\text{F}$   
 $T_{\text{K}} = \left(t_{\text{C}} \times \frac{1 \text{ K}}{1^\circ\text{C}}\right) + 273.15 \text{ K}$   
 $t_{\text{C}} = \frac{5^\circ\text{C}}{9^\circ\text{F}} \times (t_{\text{F}} - 32^\circ\text{F})$   
 $t_{\text{F}} = \left(t_{\text{C}} \times \frac{9^\circ\text{F}}{5^\circ\text{C}}\right) + 32^\circ\text{F}$

### PRESSURE

SI derived unit = pascal, Pa

- 1 Pa = 1 kg/m·s<sup>2</sup> (exact)  
 1 atm = 101,325 Pa (exact)  
 1 atm = 760 torr (exact)  
 1 torr = 1 mmHg (exact)  
 1 bar =  $10^5$  Pa (exact)  
 1 atm = 14.696 lb/in<sup>2</sup>

## FUNDAMENTAL PHYSICAL CONSTANTS

(values from 2010 CODATA)

Atomic mass unit	1 amu = $1.660538921 \times 10^{-27}$ kg	Molar gas volume, STP	$V_m = 0.022413968 \text{ m}^3/\text{mol}$ $= 22.413968 \text{ L/mol}$
Avogadro's number	$N_A = 6.02214129 \times 10^{23} \text{ mol}^{-1}$	Neutron mass	$m_n = 1.674927351 \times 10^{-27} \text{ kg}$
Electron (proton) charge	$e = 1.602176565 \times 10^{-19} \text{ C}$	Planck's constant	$h = 6.62606957 \times 10^{-34} \text{ J}\cdot\text{s}$
Electron mass	$m_e = 9.10938291 \times 10^{-31} \text{ kg}$	Proton mass	$m_p = 1.672621777 \times 10^{-27} \text{ kg}$
Faraday constant	$F = 9.64853365 \times 10^4 \text{ C/mol}$	Speed of light (in vacuum)	$c = 2.99792458 \times 10^8 \text{ m/s (exact)}$
Molar gas constant	$R = 0.08205746 \text{ L}\cdot\text{atm}/(\text{K}\cdot\text{mol})$ $= 8.314462 \text{ kPa}\cdot\text{dm}^3/(\text{K}\cdot\text{mol})$ $= 8.314462 \text{ J}/(\text{K}\cdot\text{mol})$ $= 1.9872041 \text{ cal}/(\text{K}\cdot\text{mol})$	Standard acceleration of gravity	$g = 9.80665 \text{ m/s}^2 \text{ (exact)}$
